Removes specified components of the KMIP configuration.

[mrhsm set](#) on page 995

Sets KMIP parameters.

[configure.sh](#) on page 3186

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Data Fabric client nodes, and configuring services for a node.

mrhsm init

Creates the KMIP token and initializes the KMIP configuration for first use.

Use the `mrhsm init` command to create the [KMIP](#) token for the first time and initialize the [KMIP](#) configuration. On successful initialization, the command creates the [KMIP](#) token that is used for authentication and communication with the external [KMIP](#) key store. In addition, the command generates a random user PIN used to encrypt the [KMIP](#) configuration in `/opt/mapr/conf/tokens/mrhsm.conf`.

Syntax

```
mrhsm init
[ -cacert <ca-cert> ]      Path to KMIP server CA certificate in PEM format
[ -clientcert <cert> ]     Path to client certificate in PEM format
[ -clientkey <key> ]       Path to client private key in PEM format
[ -ip <ip1,ip2,...> ]      Comma-separated list of KMIP server IP addresses
[ -kmipversion <version> ] KMIP version: 1.0, 1.1, 1.2, 1.3, or 1.4.
Default: 1.1
-label <text>              Defines the label of the object or the token.
[ -storetype file|kmip ]   Store type. Default: kmip
[ -port <kmip-port> ]      KMIP port number. Default is 5696
-sopin <so-pin>            PIN for SO (Security Officer)
```

Parameters

The list of parameters are as follows. Only the [PKCS#11](#) label and SO PIN are required; you can configure the remainder later using the [mrhsm set](#) on page 995 command.

IMPORTANT: Other than the [KMIP](#) port number and version which have default values, you must configure all parameters before you use the [mrhsm enable](#) on page 977 command to establish a connection to the [KMIP](#) server and initialize it.

cacert

The full or relative path name of the CA certificate chain in PEM format used to sign the [KMIP](#) server certificate. The Data Fabric [KMIP](#) client enforces peer validation and requires the CA certificate chain to verify the [KMIP](#) server. At the minimum, the root CA certificate is required. If an intermediate CA is used to sign the [KMIP](#) server certificate, then this file must contain all the certificates in the chain starting from the root CA certificate in PEM format.

Refer to the [KMIP](#) Integration Guide for the respective [KMIP](#) server ([Utlimaco ESKM Integration Guide](#) on page 1000, [Gemalto SafeNet KeySecure Key Manager](#) (now known as [Thales CipherTrust Manager](#)) [Integration Guide](#) on page 1015, or [Vormetric Data Security Manager \(DSM\) Integration Guide](#) on page 1030) for instructions on how to obtain the CA certificate chain.

clientcert

The full or relative path name of the CA certificate chain in PEM format used to sign the [KMIP](#) server certificate. The Data Fabric [KMIP](#) client enforces peer validation and requires the CA certificate chain to verify the [KMIP](#) server. At the minimum, the root CA certificate is required. If an intermediate CA is used to sign the [KMIP](#) server certificate, then this file must contain all the certificates in the chain starting from the root CA certificate in PEM format.

Refer to the [KMIP](#) Integration Guide for the respective [KMIP](#) server ([Utlimaco ESKM Integration Guide](#) on page 1000, [Gemalto SafeNet KeySecure Key Manager](#) (now known as [Thales CipherTrust Manager](#)) [Integration Guide](#) on page 1015, or [Vormetric Data Security Manager \(DSM\) Integration Guide](#) on page 1030) for instructions on how to obtain the client certificate.

clientkey

The full or relative path name of the client private key used to generate the client CSR.

Refer to the [KMIP](#) Integration Guide for the respective [KMIP](#) server ([Utlimaco ESKM Integration Guide](#) on page 1000, [Gemalto SafeNet KeySecure Key Manager](#) (now known as [Thales CipherTrust Manager](#)) [Integration Guide](#) on page 1015, or [Vormetric Data Security Manager \(DSM\) Integration Guide](#) on page 1030) for instructions on how to obtain the client private key.

ip

A comma-separated list of host names or IP addresses of [KMIP](#) servers. Most [KMIP](#) deployments have at least two [KMIP](#) servers in the HSM cluster for reliability and high availability. The Data Fabric [KMIP](#) client cycles through each [KMIP](#) server in the list in a round-robin manner until an accessible server is reached.

kmipversion

The [KMIP](#) version to use when communicating with the external [KMIP](#) -enabled key management appliance. Supported values are 1.0, 1.1, 1.2, 1.3 and 1.4

| | |
|------------------|--|
| | Refer to the vendor-specific documentation for information about the KMIP versions they support. At present, set this value to 1.1 for SafeNet KeySecure. Utimaco ESKM and Vormetric DSM should work with all Data Fabric supported KMIP versions. Default value is 1.1. |
| storetype | <p>A descriptor for the type of object store. Beginning with release 7.0.0, possible values are file and kmip. The default store type is set to kmip. The file option designates a file-based object store.</p> <p>Note these considerations:</p> <ul style="list-style-type: none"> • The -ip, -port, -cacert, -clientcert, -clientkey, and -kmipversion options do not apply to file-based stores. Specifying any of these options with the -storetype file option results in an error. • The mrhsm init should be invoked only once per node, regardless of whether the file or kmip store type is used. Subsequent configuration changes should be performed using mrhsm set. • Specifying -storetype file in mrhsm init sets the objectstore.backend parameter in the mrhsm configuration file \${MAPR_HOME}/conf/maprhsm.conf to a value of file. |
| label | An ASCII string which defines the label of the object or the token. The maximum length is 32 characters. |
| port | <p>The listening port number of the KMIP server. All KMIP servers in the HSM cluster must listen to the same port. Port numbers must be from 1-65535 inclusive and cannot start with a 0.</p> <p>Default is 5696.</p> |
| sopin | The PIN for the Security Officer. If not specified in the command line, a prompt will be displayed to enter the SO PIN. |

Example

The following code demonstrates an example of a sample session.

```
# mrhsm init -label "Utimaco ESKM"
Slot 0 has a free/uninitialized token.
Enter SO PIN (4-255 characters): *****
Please reenter SO PIN: *****
Generated random user PIN Ve%h*tz^G7Qev@8
```

[mrhsm remove](#) on page 993

Removes specified components of the KMIP configuration.

[mrhsm set](#) on page 995

Sets KMIP parameters.

[configure.sh](#) on page 3186

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Data Fabric client nodes, and configuring services for a node.

mrhsm rekey

Rekeys the common or core Key Encryption Keys (KEK).

Use the `mrhsm rekey` command on a CLDB node to rekey the common or core KEK, and use the core KEK to re-encrypt the CLDB and DARE keys. See [External KMIP Keystore Overview](#) on page 960 for more information on HSM keystores. See [KMIP Rekey Process](#) on page 969 for a discussion on the [KMIP](#) Rekey process.

Rekeying the Core KEK also involves decrypting the CLDB and DARE keys using the existing Core KEK before generating a new Core KEK, and then re-encrypting the CLDB and DARE keys using the new Core

KEK. This command only updates the **KMIP** configuration on the CLDB node on which this command was invoked.

On successful re-keying, copy the contents of the token directory `${MAPR_HOME}/conf/tokens` to all CLDB and ZooKeeper nodes in the cluster. Ensure that all files in the `${MAPR_HOME}/conf/tokens` directory are owned by the `mapr` user and group.

Syntax

```
# mrhsm rekey
  -keytype core|common  Specifies the key type, which is either core or
  common
  -sopin <so-pin>       PIN for SO (Security Officer)
```

Parameters

| | |
|----------------|---|
| keytype | The type of key , either common or core, to rekey. |
| sopin | The PIN for the Security Officer. If not specified in the command line, a prompt will be displayed to enter the SO PIN. |

Example

A sample session is as follows. Use `mrhsm info -kmip` to display the SHA-256 checksums of the various keys before the re-key. After the re-key, use `mrhsm info -kmip` to display the SHA-256 checksums again. The UUID and SHA-256 checksums for the CLDB and DARE keys should remain the same since the CLDB and DARE keys are not changed, but instead re-encrypted with the re-keyed Core KEK.

The UUID and SHA-256 checksum for the Core KEK is now different, since it is rekeyed.

[configure.sh](#) on page 3186

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Data Fabric client nodes, and configuring services for a node.

mrhsm remove

Removes specified components of the KMIP configuration.

Use the `mrhsm remove` command to remove various components of the [KMIP](#) configuration or to set them to their default values.

NOTE: You must set all components of the [KMIP](#) configuration to enable communication with the external [KMIP](#)-enabled key store. Therefore, if you remove any component, use the [mrhsm set](#) on page 995 command to reconfigure the settings, and then re-enable the HSM.

Syntax

```
# mrhsm remove
[ -cacert ]           Remove configured CA certificate
[ -clientcert ]       Remove configured client certificate
[ -clientkey ]        Remove configured client private key
[ -ip ]               Remove IP addresses
[ -kmipversion ]      Remove KMIP version. Reverts to 1.1
[ -port ]              Remove KMIP port number. Reverts to 5696.
-sopin <so-pin>       PIN for SO (Security Officer)
```

Parameters

cacert

The full or relative path name of the CA certificate chain in PEM format used to sign the [KMIP](#) server certificate. The Data Fabric [KMIP](#) client enforces peer validation and requires the CA certificate chain to verify the [KMIP](#) server.

clientcert

The full or relative path name of the client certificate in PEM format.

clientkey

The full or relative path name of the client private key used to generate the client CSR.

| | |

[configure.sh](#) on page 3186

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Data Fabric client nodes, and configuring services for a node.

mrhsm set

Sets KMIP parameters.

Use the `mrhsm set` command to configure [KMIP](#) settings. This command is usually run as part of the [configure.sh](#) on page 3186 script to configure the system for a fresh install or upgrade. However, you can run this command manually as the superuser (root) to change settings such as client certificates.

Syntax

```
# mrhsm set
[ -cacert <ca-cert> ]      Path to KMIP server CA certificate in PEM format
[ -clientcert <cert> ]     Path to client certificate in PEM format
[ -clientkey <key> ]       Path to client private key in PEM format
[ -ip <ip1,ip2,...> ]      Comma-separated list of KMIP server IP addresses
[ -kmipversion <version> ] KMIP version: 1.0, 1.1, 1.2, 1.3, or 1.4.
Default: 1.1
[ -storetype file|kmip ]   Store type. Default: kmip
[ -port <kmip-port> ]      KMIP port number. Default is 5696
-sopin <so-pin>           PIN for SO (Security Officer)
```

Run this command ONLY after you have configured the external [KMIP](#) server. See the appropriate Data Fabric [KMIP](#) Integration Guide ([Gemalto SafeNet KeySecure Key Manager \(now known as Thales CipherTrust Manager\) Integration Guide](#) on page 1015, [Utimaco ESKM Integration Guide](#) on page 1000, or [Vormetric Data Security Manager \(DSM\) Integration Guide](#) on page 1030, or [HashiCorp Vault Integration Guide](#) on page 1044) for instructions on how to configure the external [KMIP](#) server and obtain the CA certificate chain, client certificate, and client private key.

Set all the parameters before running the [mrhsm enable](#) on page 977 command to establish a connection to the [KMIP](#) server and initialize it.

Parameters

cacert

The full or relative path name of the CA certificate chain in PEM format used to sign the [KMIP](#) server certificate. The Data Fabric [KMIP](#) client enforces peer validation and requires the CA certificate chain to verify the [KMIP](#) server. At the minimum, the root CA certificate is required. If an intermediate CA is used to sign the [KMIP](#) server certificate, then this file must contain all the certificates in the chain starting from the root CA certificate in PEM format.

Refer to the [KMIP](#) Integration Guide for the respective [KMIP](#) server ([Gemalto SafeNet KeySecure Key Manager \(now known as Thales CipherTrust Manager\)](#))

| | |
|--------------------|--|
| | <p>Integration Guide on page 1015, Utimaco ESKM Integration Guide on page 1000, or Vormetric Data Security Manager (DSM) Integration Guide on page 1030, or HashiCorp Vault Integration Guide on page 1044) for instructions on how to obtain the CA certificate chain.</p> |
| clientcert | <p>The full or relative path name of the client certificate in PEM format. Pre-configure this certificate in the KMIP server so that the server recognizes and trusts the Data Fabric KMIP client.</p> <p>Refer to the KMIP Integration Guide for the respective KMIP server (Gemalto SafeNet KeySecure Key Manager (now known as Thales CipherTrust Manager) Integration Guide on page 1015, Utimaco ESKM Integration Guide on page 1000, or Vormetric Data Security Manager (DSM) Integration Guide on page 1030, or HashiCorp Vault Integration Guide on page 1044) for instructions on how to obtain the client certificate.</p> |
| clientkey | <p>The full or relative path name of the client private key used to generate the client CSR.</p> <p>Refer to the KMIP Integration Guide for the respective KMIP server (Gemalto SafeNet KeySecure Key Manager (now known as Thales CipherTrust Manager) Integration Guide on page 1015, Utimaco ESKM Integration Guide on page 1000, or Vormetric Data Security Manager (DSM) Integration Guide on page 1030, or HashiCorp Vault Integration Guide on page 1044) for instructions on how to obtain the private client key.</p> |
| ip | <p>A comma-separated list of host names or IP addresses of KMIP servers. Most KMIP deployments have at least two KMIP servers in the HSM cluster for reliability and high availability. The Data Fabric KMIP client cycles through each KMIP server in the list in a round-robin manner until an accessible server is reached.</p> |
| kmipversion | <p>The KMIP version to use when communicating with the external KMIP -enabled key management appliance. Supported values are 1.0, 1.1, 1.2, 1.3 and 1.4</p> <p>Refer to the vendor-specific documentation for information about the KMIP versions they support. At present, set this value to 1.1 for SafeNet KeySecure. Utimaco ESKM and Vormetric DSM should work with all Data Fabric supported KMIP versions. Default value is 1.1.</p> |
| storetype | <p>A descriptor for the type of object store. Beginning with release 7.0.0, possible values are file and kmip. The default store type is set to kmip. The file option designates a file-based object store.</p> <p>Note these considerations:</p> |

- The `-ip`, `-port`, `-cacert`, `-clientcert`, `-clientkey`, and `-kmipversion` options do not apply to file-based stores. Specifying any of these options with the `-storetype file` option, or when the existing store type is file-based, results in an error.
- Setting the `storetype` controls the `storetype` that is used for the next `mrhsm enable` or `mrhsm info` commands.
- Specifying `mrhsm set -storetype` does not require the `sopin` unless other parameters are specified.
- As in release 6.2.0, the `mrhsm set` command changes only the configuration settings in `${MAPR_HOME}/conf/tokens/mrhsm.conf` or the `objectstore.backend` in the `${MAPR_HOME}/conf/maprhsm.conf`. It does not create any keys.

port

The listening port number of the [KMIP](#) server. All [KMIP](#) servers in the HSM cluster must listen to the same port. Port numbers must be from 1-65535 inclusive and cannot start with a 0.

Default is 5696.

sopin

The PIN for the Security Officer. If not specified in the command line, a prompt will be displayed to enter the SO PIN.

mrhsm sopin

Changes the security officer PIN (SO PIN).

Use the `mrhsm sopin` to change the SO PIN, which is used by the cluster administrator to perform [PKCS#11](#) file or [KMIP](#) store modifications.

Syntax

```
# mrhsm sopin
  [ -oldsopin <PIN> ]
  [ -newsopin <PIN> ]
```

The `mrhsm sopin` can be called with or without the `-oldsopin <PIN>` or `-newsopin <PIN>` parameters. If either parameter is not used while issuing the `mrhsm sopin` command, the system prompts you to specify the old or new SO PIN accordingly.

The PIN you specify can be 4-255 characters. All characters are allowed, including combinations of alphabetic, numeric, and special characters.

See [About the SO PIN](#) on page 999 for more information.

Parameters

oldsopin

The `-oldsopin <PIN>` parameter requires you to specify the current SO PIN.

newsopin

The `-newsopin <PIN>` parameter assigns a new SO PIN.

Example

```
# mrhsm sopin
Current SO PIN: ****
Enter new SO PIN (4-255 characters): ****
Please reenter new SO PIN: ****
New SO PIN is set successfully
```

Related concepts

[About the SO PIN](#) on page 999

The Security Officer PIN (SO PIN) is a string of at least four characters that the cluster administrator must supply to perform certain operations that modify the PKCS#11 file or KMIP store.

Related reference

[configure.sh](#) on page 3186

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Data Fabric client nodes, and configuring services for a node.

About the SO PIN

The Security Officer PIN (SO PIN) is a string of at least four characters that the cluster administrator must supply to perform certain operations that modify the PKCS#11 file or KMIP store.

How the SO PIN Is Used

In a KMIP environment, the cluster admin must enter the SO PIN to change certain system settings, which can include:

- Rekeying the common or core KEK keys.
- Setting a new client certificate to replace an expired certificate.
- Configuring KMIP IP addresses.

In the file-store environment:

- The SO PIN prevents unauthorized configuration changes to the PKCS#11 store.
- The cluster admin does not need to use the SO PIN directly, but it is a best practice to change it to something other than the default value.
- You must provide the SO PIN only during an `mrhsm rekey` operation. `mrhsm rekey` creates a new Core KEK, which is used to encrypt the CLDB key and DARE key.
- The SO PIN becomes more useful if the cluster is later reconfigured to use an external KMIP keystore.

Specifying the SO PIN

The SO PIN is configured during the initial invocation of `configure.sh` after you specify the `-hsmopin <so-pin>` parameter. See [configure.sh](#) on page 3186. The PIN you specify can be 4-255 characters. All characters are allowed, including combinations of alphabetic, numeric, and special characters.

Default SO PIN

For a new installation of a release 7.0.0 or later Data Fabric cluster, the default SO PIN is 1234 unless you specify the SO PIN after you use `configure.sh`.

Changing the SO PIN

To change the SO PIN, use the `mrhsm sopin` command. The command requires you to specify the old (current) and new SO PIN values. For example:

```
# mrhsm sopin
Current SO PIN: ****
Enter new SO PIN (4-255 characters): ****
Please reenter new SO PIN: ****
New SO PIN is set successfully
```

If You Lose the SO PIN

Losing or forgetting the SO PIN does not affect normal cluster operations but prevents certain KMIP configuration changes. See FAQ #2 in [Frequently Asked Questions](#) on page 1055.

Upgrading and the SO PIN

By default, the Data Fabric software initializes `mrhsm` using the same default `hsm` label and SO PIN as done during a new release 7.0.0 installation (if `mrhsm` has not already been initialized). You can change default values by specifying `-hsmlabel <label>` and `-hsmsopin <so-pin>` options in `configure.sh`. See [Upgrade Notes \(Release 8.1\)](#) on page 44.

Integration Guides

This section contains the Data Fabric integrations guides with external vendors for KMIP.

The vendors currently supported are:

Utimaco ESKM Integration Guide

Describes how to integrate the Data Fabric platform with the Utimaco ESKM server.

This integration guide outlines the steps required to integrate the Data Fabric platform with the [Utimaco Enterprise Software Key Manager \(ESKM\) server](#):

- For a fresh installation, perform the following steps before installing the Data Fabric platform.
- For an upgrade, perform these steps before running the [configure.sh](#) on page 3186 script.

The difference between the fresh installation and upgrade is that for a fresh installation, the CLDB and DARE master keys are generated by the ESKM and saved in the ESKM for disaster recovery purposes, whereas for an upgrade, the existing CLDB and DARE master keys are used.

The Data Fabric integration will work with any ESKM release from 4.0 onwards, although this integration guide is based on the ESKM 5.2 release. Changes in the ESKM user interface and functionality in different ESKM releases may affect the steps outlined in this integration guide. Refer to the **Utimaco ESKM documentation** (get it from the vendor) for the authoritative guide for the ESKM appliance.

The steps to integrate Data Fabric platform are as follows:

1. Install and set up the ESKM
2. Download the CA Certificate
3. Create and download the client certificate
4. Create the [KMIP](#) group and user

Step 1: Install and Setup ESKM

Describes how to install and setup Utimaco ESKM server.

To start, install and set up the ESKM server using the steps in the **ESKM Read Me First** and **ESKM 5.2 Installation and Replacement Guide** (get them from the vendor). If you are using an existing ESKM appliance, you can skip this installation and setup step. At the end of this step, you should have obtained the following:

1. IP address of the ESKM server.
2. **KMIP** port number of the ESKM server. The default **KMIP** port number is 5696.
3. The Local CA certificate.

Step 2: Download the Local CA Certificate

Describes how to download the local CA certificate from the ESKM server.

Download the local CA certificate from the ESKM server, and install it on the Data Fabric platform.

1. From the Admin UI, navigate to the **Security > Local CA** page. Click the local CA in the CA Name column in the Local Certificate Authority List section. The details of the local CA are displayed as shown in the following example:

2. Click **Download** to download the CA certificate. In this example, it should be saved as `LocalCA.crt`.

[configure.sh](#) on page 3186

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Data Fabric client nodes, and configuring services for a node.

Step 3: Download the Client Certificate

Describes how to create and download the local client certificate from the ESKM server.

This section describes the steps to obtain a client certificate that is signed by the local CA of the ESKM. You can also import custom client certificates from a trusted CA. For more information, refer to Chapter 4 in the *Certificate Procedures* and *Certificate Authority Procedures* section of the **ESKM 5.2 User Guide** (get it from the vendor).

The steps required to create and download the client certificate are as follows:

1. Generate the certificate signing request (CSR).
2. Sign the CSR.
3. Download the signed client certificate.
4. Install the signed client certificate.

Generate the Certificate Signing Request (CSR)

Describes how to generate a CSR using OpenSSL.

To generate the CSR:

Use OpenSSL. In this example, the client private key is saved in a file named `client.key`, and the CSR is saved in a file named `client.csr`:

```
$ openssl req -newkey rsa:2048 -nodes -keyout client.key -out client.csr
Generating a 2048 bit RSA private key
.....+++
.....+++
writing new private key to 'client.key'
-----
You are about to be asked to enter information that will be incorporated
into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [XX]:US
State or Province Name (full name) []:California
Locality Name (eg, city) [Default City]:Santa Clara
Organization Name (eg, company) [Default Company Ltd]:HPE
Organizational Unit Name (eg, section) []:MapR
Common Name (eg, your name or your server's hostname) []:maprkmipclient1
Email Address []:security@hpe.com

Please enter the following 'extra' attributes
to be sent with your certificate request
A challenge password []:
An optional company name []:
```

In this example, the client private key is saved in a file name `client.key`, and the CSR is saved in a file named `client.csr`.

Describes how to sign a CSR.

To sign the CSR:

1. From the Certificate Name section, click the CSR that you just generated. In the example, it is `maprkmipclient1`.
2. The CSR properties are displayed. Select the contents of the CSR starting from `-----BEGIN CERTIFICATE REQUEST-----` to `-----END CERTIFICATE REQUEST-----` and copy the contents to the clipboard.
3. Navigate to **Security > Local CAs** and click the Sign Request option corresponding to the local CA in the Local Certificate Authority List listing. Then:
 - a. Select Client for Certificate Purpose.
 - b. Change the Certificate Duration if needed.

- c. Paste the contents of the CSR that you previously copied to the clipboard, to the Certificate Request section.
- d. Click Sign Request to sign the CSR.

-----END CERTIFICATE-----
```

Cancel OK

4. Copy the contents of the signed client certificate starting with -----BEGIN CERTIFICATE----- and ending with -----END CERTIFICATE----- to your clipboard.

TIP:

If you have overwritten the clipboard contents, you can obtain the signed client certificate using the following steps:

1. Navigate to **Security > Local CAs**.
2. Click **Show Signed Certs**.
3. In the **Signed Certificates** section, select the certificate matching the CN and other details that you configured in Step 1 from the list. In this example, the certificate is `maprkmpclient1`.
4. Click **Properties**. The Signed Certificate Information page appears.
5. Copy the contents of the signed client certificate starting with `-----BEGIN CERTIFICATE-----` and ending with `-----END CERTIFICATE-----` to your clipboard.

Download the Signed Client Certificate

Describes how to download a signed client certificate to the Data Fabric system.

After you have installed your signed client certificate on the ESKM server, you need to download it to the Data Fabric hosts running the [KMIP](#) client, that is. the Data Fabric CLDB hosts. To do this:

1. Click **Security > Certificates**, and navigate to the `Certificate List` section.
2. Select the certificate where the Certificate Name matches the Common Name (CN) that you specified when creating your CSR. Then click **Properties**. The Certificate Information page is displayed.
3. Click **Download** to download the client certificate to your Data Fabric CLDB host. In the example, since the CN for the certificate is `maprkmipclient1`, the signed client certificate is saved to a file named `maprkmipclient1.crt` in PEM format.

[configure.sh](#) on page 3186

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Data Fabric client nodes, and configuring services for a node.

Step 4: Create the Data Fabric KMIP Group and User for the Cluster

Describes how to create the KMIP group and user to store cluster keys on the ESKM server.

You now need to create a [KMIP](#) user/object group pair to store your keys. As [KMIP](#) keys for Data Fabric are cluster-specific, you should create a different [KMIP](#) user/object group pair for each cluster so that each cluster can only access its own [KMIP](#) keys.

Create the Cluster-Specific Data Fabric KMIP Group

To create a cluster-specific **KMIP** group:

1. Navigate to **Security > Local Users & Groups > Local Groups** and click **Add**.
2. Enter the name of the group in the format **mapr-<cluster>** where **<cluster>** is the cluster name.
3. In the drop-down box for the Group Type, select **KMIP**.
4. Click **Next**.

The system displays a confirmation page to create two **KMIP** groups:

- A **KMIP** user group called **mapr-<cluster>_user**
- A **KMIP** object group called **mapr-<cluster>**

5. Click **Save**.

The system creates two **KMIP** groups. In this example, the Data Fabric cluster is named **my.cluster.com**. Therefore, the system creates the **KMIP** group pair: **mapr-my.cluster.com** object group, and **mapr-my.cluster.com_user** user group, as shown.

Create the Data Fabric KMIP User for the Cluster

To create the **KMIP** user:

1. Navigate to **Security > Local Users & Groups > Local Users** and click **Add**. The Create Local User page appears.
2. Enter the information for the local user:
 - a. The user name must match the CN of the client certificate. In the example, the CN for the client certificate is **maprkmipclient1**, and therefore this is also the user name.
 - b. The User Administration Permission and Change Password Permission fields do not apply to **KMIP** groups, so leave these unchecked.
 - c. Check the Enable KMIP option.
 - d. Leave the Map non-existent Object Group to x-Object Group option unchecked.
 - e. Set the **KMIP** User Group to the user group that you created earlier. In this example, the user group is **mapr-my.cluster.com_user**.

3. Click **Create**. The system creates the **KMIP** user (maprkmipclient1 in this example), and returns to the Local Users listing.

At the end of this phase, you should have the following files that are needed to set up your Data Fabric **KMIP** client, in addition to the list of IP addresses and port number of the key management appliances:

- The CA used to sign the client certificate. This is the local CA that is downloaded from the ESKM.
- The signed client certificate that was signed by the KeySecure local CA and downloaded from the ESKM.
- The client private key which was generated using OpenSSL.

Continue the setup on the Data Fabric CLDB node using the [configure.sh](#) on page 3186 script with the HSM parameters, or the [mrhsm Commands](#) on page 975.

Gemalto SafeNet KeySecure Key Manager (now known as Thales CipherTrust Manager) Integration Guide

Describes how to integrate the Data Fabric platform with the Gemalto SafeNet KeySecure Key Manager (now known as Thales CipherTrust Manager).

The Data Fabric integration should work with any [KMIP-enabled SafeNet KeySecure Key Manager](#), although this integration guide is based on the KeySecure 8.11.1 release. Changes in the SafeNet KeySecure user interface and functionality in different KeySecure releases may affect the steps outlined in this integration guide. Refer to the **SafeNet KeySecure documentation** (get it from the vendor) for the authoritative guide for the KeySecure appliance.

This guide assumes that the SafeNet KeySecure Local CA is used to sign the client certificate. This may not always be the case in production deployments, since trusted CA's may be imported. Refer to the **SafeNet KeySecure Appliance Installation and Configuration Guide** (get it from the vendor) for details on how to configure and/or import CAs and client certificates.

The integration steps are as follows:

1. Install and set up the SafeNet KeySecure appliance
2. Download the CA certificate
3. Create and download the client certificate
4. Create the local group and user

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Data Fabric client nodes, and configuring services for a node.

Step 1: Install and set up the SafeNet KeySecure Appliance

Describes how to install and configure the Gemalto SafeNet KeySecure Appliance (now known as Thales CipherTrust Manager).

To start, install and set up the SafeNet KeySecure Appliance by following the steps in the **SafeNet KeySecure Appliance Installation and Configuration Guide** (get it from the vendor). You must enable the [KMIP](#) server following the instructions in *Chapter 5, Adding A KMIP Server* as mentioned in that guide. If you are using an existing KeySecure appliance, you can skip the installation and setup step. At the end of this installation, you should have obtained the following:

1. IP address of the SafeNet KeySecure appliances in the cluster.
2. [KMIP](#) port number of the KeySecure appliance. The default [KMIP](#) port number is 5696. All KeySecure appliances in the cluster must have the same port number.
3. The Local CA certificate

Sets KMIP parameters.

[configure.sh](#) on page 3186

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Data Fabric client nodes, and configuring services for a node.

Step 3: Create and Download the Client Certificate

Describes the steps to obtain a client certificate that is signed by the local CA of the SafeNet KeySecure appliance.

Alternatively, you can import custom client certificates from a trusted CA. Refer to the SafeNet KeySecure documentation for more details.

The steps required to create and download the client certificate are as follows:

1. Generate the certificate signing request (CSR).
2. Sign the CSR.
3. Download the signed client certificate.

[configure.sh](#) on page 3186

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Data Fabric client nodes, and configuring services for a node.

Generate the Certificate Signing Request (CSR)

Describes how to generate the CSR

Before you can obtain a signed client certificate, you need to first generate a Certificate Signing Request. One way to do this is using OpenSSL. For example:

```
openssl req -newkey rsa:2048 -nodes -keyout client.key -out client.csr

Generating a 2048 bit RSA private key
.....+++
.....+++
writing new private key to 'client.key'
-----
You are about to be asked to enter information that will be incorporated
into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [XX]:US
State or Province Name (full name) []:California
Locality Name (eg, city) [Default City]:Santa Clara
Organization Name (eg, company) [Default Company Ltd]:HPE
Organizational Unit Name (eg, section) []:MapR
Common Name (eg, your name or your server's hostname) []:safenetclient1
Email Address []:

Please enter the following 'extra' attributes
to be sent with your certificate request
A challenge password []:
An optional company name []:
```

In this example, the client private key is saved in a file name `client.key`, and the CSR is saved in a file named `client.csr`.

Download Back

For configuring the client certificate section of the local user, copy the contents of the signed client certificate starting with -----BEGIN CERTIFICATE----- and ending with -----END CERTIFICATE----- to your clipboard.

TIP:

If you have overwritten the clipboard contents, you can obtain the signed client certificate using the following steps:

1. Navigate to **Security > Local CAs**.
2. Click **Show Signed Certs**.
3. In the **Signed Certificates** section, select the certificate matching the CN and other details that you configured in Step 1 from the list. In this example, the certificate is `safenetc1ent1`.
4. Click **Properties**. The **Signed Certificate Information** page appears.
5. Copy the contents of the signed client certificate starting with -----BEGIN CERTIFICATE----- and ending with -----END CERTIFICATE----- to your clipboard.

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Data Fabric client nodes, and configuring services for a node.

Step 4: Create the KMIP User for the Cluster

Describes how to create a KMIP user on the Data Fabric cluster to store SafeNet Key Secure credentials.

You need to create the [KMIP](#) user for the Data Fabric cluster. To do this:

1. Navigate to **Local Authentication > Local Users & Groups** and then click **Add** in the Local Users section.

NOTE: The user name must match the common name in your client certificate for the [KMIP](#) certificate authentication to succeed. In this example, since the CN for the client certificate is `safenetcclient1`, the username must also be `safenetcclient1`:

Security > Local Authentication > Local Users & Groups

User & Group Configuration

Local Users Help ?

Filtered by: --- where value contains Set Filter

Items per page: 10 Submit

| Username | Password | User Administration Permission | Change Password Permission | Password Expiration |
|---------------------------------|----------|--------------------------------|----------------------------|---------------------|
| mapr-perfnod95 | ***** | ☐ | ☐ | None |
| safenetcclient1 | ***** | ☐ | ☐ | |

1 - 1 of 1

Save Cancel

2. Enter the password for the user. This is required when creating a user, but is not used for [KMIP](#), as authentication is performed using certificate authentication. You do not need to check the User Administration Permission and Change Password Permission boxes, as these are not used for [KMIP](#).
3. Click **Save** to create the user. The newly created user is added to the Local Users listing, as shown in the following example:

At the end of this phase, you should have the following files that are needed to set up your Data Fabric [KMIP](#) client, in addition to the list of IP addresses and port number of the key management appliances:

- The CA used to sign the client certificate. This is the local CA that is downloaded from the Gemalto SafeNet KeySecure Key Manager.
- The signed client certificate that was signed by the KeySecure local CA and downloaded from the KeySecure appliance.
- The client private key which was generated using OpenSSL.

Continue the setup on the Data Fabric CLDB node using the [configure.sh](#) on page 3186 script with the HSM parameters, or the [mrhsm Commands](#) on page 975.

Describes how to integrate the Data Fabric platform with the Vormetric Data Security Manager.

This chapter discusses how to set up the [Vormetric Data Security Manager \(DSM\)](#) and prepare it for integration with the Data Fabric [KMIP](#) client.

Data Fabric integration works with any DSM release that supports [KMIP](#) 1.0-1.4, although this integration guide is based on the Data Security Manager Release 6. Changes in the DSM user interface and functionality in different DSM releases may affect the steps outlined in this integration guide. For more information, refer to the Vormetric DSM documentation for the authoritative guide for the DSM appliance:

- **Data Security Manager Release 6 Installation and Configuration Guide**
- **Data Security Manager DSM Release 6 Administration Guide** (get these two guides from the vendor)

This chapter provides an overview of DSM setup and installation as it relates to the Data Fabric core platform and [KMIP](#). DSM requires a [KMIP](#) license in order to run the [KMIP](#) server and connect [KMIP](#) clients to the DSM. Details of how to set up and manage [KMIP](#) in DSM can be found in *Chapter 25: Key Management Interoperability Protocol* of the **Data Security Manager DSM Release 6 Administration Guide** (get it from the vendor).

It is assumed that the Vormetric DSM Local CA is used to sign the client certificate. This may not always be the case in production deployments, since trusted CA's may be imported. Refer to the **Vormetric DSM Administration Guide** (get it from the vendor) for details on how to configure and/or import CAs and client certificates.

The steps for integration are as follows:

1. Install and set up the DSM, including high availability
2. Install the [KMIP](#) license

3. Install the [KMIP](#) trusted CA certificate
4. Create and download the client certificate
5. Create the [KMIP](#) group and user
6. Create a [KMIP](#)-enabled DSM domain

Step 2: Install the KMIP License

Upload KMIP License for Vormetric DSM.

The Vormetric DSM requires a [KMIP](#) license to run. If this is not already done during the previous step, upload your [KMIP](#) license now. Ensure that Agent Type column of your license display includes KMIP, as shown in the following example:

| Agent Type | Term License | Perpetual License | Hourly License | LDT License | Docker License | Efficient Storage License | FF1 License |
|------------|-----------------|-------------------|-----------------|-----------------|----------------|---------------------------|-------------|
| | Agents Licensed | Cores Licensed | Expiration Date | Agents Licensed | Cores Licensed | | |
| FS | 20 | Unlimited | 31 Jan 2021 | 0 | 0 | 0 | N/A |
| Key | 20 | Unlimited | 31 Jan 2021 | 0 | 0 | N/A | 20 |
| KMIP | 20 | Unlimited | 31 Jan 2021 | 0 | 0 | N/A | N/A |

For more details on the [KMIP](#) license, refer to the *Enable the DSM for KMIP* section in the **Key Management Interoperability Protocol** chapter of the **Vormetric DSM Administration Guide** (get it from the vendor).

Step 3: Install the KMIP Trusted CA Certificate

Illustrates how to upload an external CA certificate to the DSM.

The Vormetric DSM requires that the CAs used to sign the client certificate be obtained from an external source and uploaded to the DSM. After you have obtained the external CA certificate:

1. Log on to the DSM as an administrator of type **System Administrator** or **All**.
2. Navigate to **System > KMIP Trusted CA Certificates**.
3. In the KMIP CA section, click **Choose File** to select the external CA certificate.
4. Click **Import/Update Certificate** to import the certificate.

On successful completion, the external CA is uploaded to the DSM and displayed in the [KMIP](#) CA listing as shown in the following example.:

For details, refer to the *Establish Trust Between DSM and KMIP Client* section in the *Key Management Interoperability Protocol* chapter of the **Vormetric DSM Administration Guide** (get it from the vendor).

Enables external KMIP keystore support.

[mrhsm get](#) on page 980

Retrieves the contents of the CA and client certificates, and puts them in a file.

[mrhsm info](#) on page 981

Displays HSM configuration information.

[mrhsm init](#) on page 987

Creates the KMIP token and initializes the KMIP configuration for first use.

[mrhsm rekey](#) on page 990

Rekeys the common or core Key Encryption Keys (KEK).

[mrhsm remove](#) on page 993

Removes specified components of the KMIP configuration.

[mrhsm set](#) on page 995

Sets KMIP parameters.

[configure.sh](#) on page 3186

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Data Fabric client nodes, and configuring services for a node.

Step 4: Create a KMIP-Enabled Domain

Describes how to create a KMIP-enabled domain to add KMIP clients.

To create a [KMIP](#)-enabled domain where you can add your [KMIP](#) clients:

1. Navigate to **Domains > Manage Domains**.
2. Click **Add**.
3. Enter the domain name.
4. Select the **Enable KMIP** option.
5. Click **Apply** to create the domain, as shown in the following example:

| Dashboard Domains - Administrators - High Availability Reports Log - System - | |
|---|-------------------------------------|
| Add Domain | |
| <div> <div>General</div> <div>Assign Admin</div> <div>License</div> </div> | |
| *Name | dsmaprqa |
| Organization | HPE |
| Description | MapR QA Test Domain |
| Help Desk Information | |
| Enable KMIP | ☒ |
| <div>Ok Apply Cancel</div> | |

6. Click the **Assign Admin** tab to assign an administrator to this domain. Select the administrator from the list. In this example, this is administrator `alladmin` with administrative privileges of type `All`. Then, click **OK**:

Dashboard Domains - Administrators - High Availability Reports Log - System -

Edit Domain - dsmmaprqa

General Assign Admin License

View 20 Total: 1

Page 1 of 1

| Selected | Name | Status |
|-------------------------------------|----------|-----------------------------|
| ☒ | alladmin | User not assigned to domain |

Page 1 of 1

Disable Administrators Ok Apply Cancel

The domain is then added to the list of domains, as shown in the following example:

Sets KMIP parameters.

[configure.sh](#) on page 3186

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Data Fabric client nodes, and configuring services for a node.

Step 5: Add the KMIP Client to the Domain

Describes how to add the KMIP client to the KMIP-enabled domain.

To add the [KMIP](#) client to the [KMIP](#)-enabled domain:

1. Obtain a signed client certificate.
2. Add the [KMIP](#) host to the domain.
3. Import the signed client certificate associated with this [KMIP](#) host.

IMPORTANT: The Common Name (CN) field of the signed client certificate must match the host name.

The certificate can either be self-signed certificate or a signed by an external CA that is trusted by the DSM. In this example, the [KMIP](#) trusted CA certificate is already installed in Step 3, and will be used to sign the CSR.

To obtain a signed client certificate:

1. Use OpenSSL to create a Certificate Signing Request (CSR) that will be used to sign the client certificate. Note that the name we entered into the Common Name field is dsmqatest, which must match the [KMIP](#) host name in a later step:

```
[root@qa-node125 vormetric_dsm_qa]# openssl req -newkey
rsa:2048 -nodes -keyout dsmqatest.key -out dsmqatest.csr
Generating a 2048 bit RSA private key
.....+++
+++
writing new private key to 'dsmqatest.key'
-----
You are about to be asked to enter information that will be incorporated
into your certificate request.
What you are about to enter is what is called a Distinguished Name or a
DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [XX]:US
State or Province Name (full name) []:San Jose
Locality Name (eg, city) [Default City]:California
Organization Name (eg, company) [Default Company Ltd]:Hewlett-Packard
Enterprise
Organizational Unit Name (eg, section) []:MapR
Common Name (eg, your name or your server's hostname) []:dsmqatest
Email Address []:

Please enter the following 'extra' attributes
to be sent with your certificate request
A challenge password []:
An optional company name []:
```

2. Get the certificate signed by the trusted CA.

To add the [KMIP](#) host to the domain:

1. Log on to the DSM Web UI as an administrator with privileges of type All. In our example, the administrator is alladmin.
2. Navigate to **Domains > Switch Domains** and select the domain you have just created. In this example, the domain is dsmmaprqa.
3. Click **Switch to domain**:

4. From the Hosts menu, click **Hosts**:

5. Click **Add**. Enter the following information in the Add Host dialog:
 - a. The Host Name must match EXACTLY with the common name (CN) that you have configured in your **KMIP** client certificate. In this example, the CN is dsmqatest, so the hostname must also be dsmqatest.
 - b. Leave the **Password Creation Method** at its default value of Generate.
 - c. DO NOT select the **Automatically Assign to a Server** option.
 - d. Enter a description for the **KMIP** client.
 - e. Select the license type. This must match the **KMIP** license that you have configured for this DSM. After you enter the correct license type, a few license choices appear. Select **TERM** as the license type.
 - f. Select the **KMIP** option.
 - g. Select the **Communication Enabled** option to enable your **KMIP** client to communicate with the DSM **KMIP** server.
 - h. Click **Ok** to add the **KMIP** client.

The KMIP client is then added to the list of hosts, as shown in the following example:

The screenshot shows the 'Hosts' management page. At the top, there is a search bar with 'Host Name Contains' and 'Agent Type' set to 'All'. Below the search bar, there are buttons for 'Add', 'Delete', and 'Import'. A table lists the hosts, with columns for 'Select', 'OS Type', 'Host Name', 'FS Agent', 'Key Agent', 'KMIP', 'One Way Communication', 'Delete', 'License Type', 'LDT', 'Docker', 'Efficient Storage', and 'Description Sharing'. The host 'dsmqatest' is selected, and the 'KMIP' agent type is highlighted. The table shows that the 'KMIP' agent is enabled for this host.

| Select | OS Type | Host Name | FS Agent | Key Agent | KMIP | One Way Communication | Delete | License Type | LDT | Docker | Efficient Storage | Description Sharing |
|-------------------------------------|---------|-----------|----------|-----------|------|-----------------------|--------|--------------|-----|--------|-------------------|---------------------|
| ☒ | Unknown | dsmqatest | N/A | | | | | TERM | | | | MapR QA Test Client |

To import the **KMIP** certificate for the host:

1. Click the Host Name field, which is dsmqatest in the example.
2. Scroll down to the end of the Edit Hosts page and click **Import KMIP Cert**:

The screenshot shows the 'Edit Host - dsmqatest' page. The 'Host Information' section includes fields for Name (dsmqatest), OS Type (Unknown), FS Communication Port (7024), License Type (TERM), FS Agent Locked, Support Challenge & Response, Password Creation Method (Generate), Docker, Efficient Storage, and Secure Start GuardPoint. The 'Agent Information' section shows a table with columns for Agent, Version, Certificate Fingerprint, Registration Allowed, and Communication Enabled. The 'KMIP' agent is selected, and the 'Import KMIP Cert' button is visible at the bottom.

| Agent | Version | Certificate Fingerprint | Registration Allowed | Communication Enabled |
|-------|---------|-------------------------|-------------------------------------|-------------------------------------|
| FS | | | ☐ | ☐ |
| Key | | | ☐ | ☐ |
| KMIP | | | ☒ | ☒ |

3. Click **Choose File** to select the client certificate that you have created.

IMPORTANT: If you are uploading a client certificate signed by an external CA, then that external CA must first be configured into the DSM.

4. Click **OK** to import the client certificate. The certificate is then imported, as shown in the following example:

The integration is now complete. You should have the following pieces of information, either downloaded from the DSM or obtained externally:

- DSM CA certificate used to sign the **KMIP** server certificate
- **KMIP** client certificate
- **KMIP** client private key
- IP addresses of DSM servers
- **KMIP** port number (default 5696)

To test the **KMIP** connection, view the **KMIP** objects under **Keys > KMIP Objects** as shown in the following example:

At the end of this phase, you should have the following files that are needed to set up your Data Fabric [KMIP](#) client, in addition to the list of IP addresses and port number of the key management appliances:

- The CA used to sign the client certificate. This is the local CA that is downloaded from the Vormetric DSM.
- The signed client certificate that was signed by the KeySecure local CA and downloaded from the Vormetric DSM.
- The client private key which was generated using OpenSSL.

Continue the setup on the Data Fabric CLDB node using the [configure.sh](#) on page 3186 script with the HSM parameters, or the [mrhsm Commands](#) on page 975.

HashiCorp Vault Integration Guide

Describes how to integrate the Data Fabric platform with HashiCorp Vault.

This chapter discusses how to set up [HashiCorp Vault](#) and prepare it for integration with the Data Fabric [KMIP](#) client.

Data Fabric integration works with HashiCorp release versions from 1.5.0+ent onwards, although this integration guide is based on the Vault 1.5.3+ent release. Changes in the Vault user interface and functionality in different Vault releases may affect the steps outlined in this integration guide. For more information, refer to the HashiCorp Vault documentation for the authoritative guide for the Vault appliance.

This chapter assumes that the HashiCorp Vault Local CA is used to sign the client certificate. This may not always be the case in production deployments, since trusted CAs may be imported. Refer to the HashiCorp Vault documentation for details on how to configure and/or import CAs and client certificates. Steps 2-4 are outlined in [HashiCorp's Guide](#) for deploying Vault's [KMIP](#) secrets engine.

The steps for integration are as follows:

1. Install and set up Vault
2. Enable and Configure the [KMIP](#) secrets engine
3. Create Scopes and Rules
4. Generate the CA and Client certificate

Sets KMIP parameters.

[configure.sh](#) on page 3186

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Data Fabric client nodes, and configuring services for a node.

Step 1: Install and Set Up the Vault

Explains how to setup HashiCorp Vault.

To start, install and set up the Vault. [HashiCorp's Vault Deployment Guide](#) might be a helpful resource to use. If you are using an existing Vault appliance, make sure that the version is at least 1.5.0+ent . If so, you can skip the installation.

This guide walks you through enabling and configuring the [KMIP](#) secrets engine in the next step.

Sets KMIP parameters.

[configure.sh](#) on page 3186

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Data Fabric client nodes, and configuring services for a node.

Step 2: Configure KMIP Secrets Engine

Explains how to setup the KMIP secrets engine.

This guide uses CLI commands but these steps can be accomplished through the Web UI as outlined in [HashiCorp's Vault Deployment Guide](#).

1. Create and set policies to allow the Secrets engine to work. The following permissions are needed to successfully perform all the steps in this guide:

```
# Work with kmip secrets engine
path "kmip/*" {
  capabilities = [ "create", "read", "update", "delete", "list" ]
}

# Enable secrets engine
path "sys/mounts/*" {
  capabilities = [ "create", "read", "update", "delete", "list" ]
}

# List enabled secrets engine
path "sys/mounts" {
  capabilities = [ "read", "list" ]
}
```

2. Write these permissions to a new file called `kmip-policy.hcl`:

```
$ tee kmip-policy.hcl <<EOF
# Work with kmip secrets engine
path "kmip/*" {
  capabilities = [ "create", "read", "update", "delete", "list" ]
}

# Enable secrets engine
path "sys/mounts/*" {
  capabilities = [ "create", "read", "update", "delete", "list" ]
}

# List enabled secrets engine
path "sys/mounts" {
  capabilities = [ "read", "list" ]
}
EOF
```

3. Load this policy into the active configuration:

```
$ vault policy write kmip kmip-policy.hcl
Success! Uploaded policy: kmip
```

- Now that the correct policies are enabled, start to set up the [KMIP](#) secrets engine. First enable the engine using the command:

```
vault secrets enable kmip
```

- Set up the configuration. Find out the machine's IP address as well as the port that you want to use for [KMIP](#). This guide assumes the port used for the [KMIP](#) server is 5696. To configure Vault's [KMIP](#), run:

```
$ vault write kmip/config listen_addrs=<Host's IP Address>:5696
```

The [KMIP](#) configuration should be similar to the following:

```
$ vault read kmip/config
Key                               Value
---                               -
default_tls_client_key_bits       256
default_tls_client_key_type       ec
default_tls_client_ttl            336h
listen_addrs                      [0.0.0.0:5696]
server_hostnames                  [localhost]
server_ips                        [127.0.0.1 ::1]
tls_ca_key_bits                   256
tls_ca_key_type                   ec
tls_min_version                   tls12
```

The [KMIP](#) secrets engine is now properly configured.

[configure.sh](#) on page 3186

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Data Fabric client nodes, and configuring services for a node.

Step 3: Create Scopes and Rules

Explains how to setup Scopes and Rules.

Scopes partition [KMIP](#) managed object storage into multiple named buckets, while Roles in the [KMIP](#) secrets engine determine the set of [KMIP](#) operations that [KMIP](#) clients are allowed to perform.

1. Create a Scope. In this example, it is named `mapr`.

```
$ vault write -f kmip/scope/mapr
```

2. Create a new Role under the example Scope `mapr`. Name the Role `maprkmipclient1`.

```
$ vault write kmip/scope/mapr/role/maprkmipclient1 operation_all=true
```

The Role should be displayed as follows:

```
$ vault read kmip/scope/mapr/role/maprkmipclient1
Key          Value
---          -
operation_all true
tls_client_key_bits 0
tls_client_key_ttl   0s
tls_client_key_type  n/a
```

Sets KMIP parameters.

[configure.sh](#) on page 3186

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Data Fabric client nodes, and configuring services for a node.

Step 4: Generate the CA and the Client Certificate

Explains how to generate the CA and the Client certificate to install on the Data Fabric platform.

Download the local CA certificate from the Vault, as well as create and download the client certificates and install them on the Data Fabric platform.

1. Retrieve the CA certificates:

```
$ vault read kmip/ca
Key      Value
---      -
ca_pem   -----BEGIN CERTIFICATE-----
MIICNzCCAzigAwIBAgIUP8qJ5bh/nsBeAh2V61xuBYgf+8swCgYIKoZIzj0EAwIw

/zxa8PYxFi62BpmjIKPsyw4U7l0rJ0JBMn3unS8=
-----END CERTIFICATE-----
```

The **bold** block is part of the response that is your CA certificate. Copy this into a file called `ca.pem` using your favorite text editor.

2. Generate a certificate in PEM format and save it to a JSON file named `credential.json`:

```
$ vault write -format=json \
  kmip/scope/mapr/role/maprkmipclient1/credential/generate \
  format=pem > credential.json
```

3. Extract the private key from the `credential.json` file using the `jq` tool and save it in a file named `key.pem`:

```
$ jq -r .data.private_key < credential.json > key.pem
```

4. Find the certification serial numbers associated with the `maprkmipclient1` role:

```
$ vault list kmip/scope/mapr/role/maprkmipclient1/credential
Keys
-----
693751915900546682090704263335075174345458639865
```

In this example, the key is 693751915900546682090704263335075174345458639865 but your serial number may be different. Copy this down for the next step.

5. Lookup the client and CA certificates using this serial number (make sure to use your own serial number):

```
$ vault read kmip/scope/mapr/role/maprkmipclient1/credential/lookup \
  serial_number=693751915900546682090704263335075174345458639865

```

In the preceding response, the **bold** block is the CA certificate, which should look similar to the CA certificate saved earlier, while the *italics* block is the client certificates. Save the client certificates to a file called `cert.pem` using your text editor.

6. Combine the `cert.pem` and the `key.pem` files to create a file called `client.pem`, which is the file that the `mrhsm` commands use.

This concludes the Vault-specific setup and configuration steps. At the end of this phase, you should have the following files that are needed to set up your Data Fabric [KMIP](#) client, in addition to the list of IP addresses and the port number of the key management appliances:

1. The CA used to sign the client certificate. This is contained in `ca.pem`.
2. The signed client certificate contained in `client.pem`.
3. The client private key which is contained in `key.pem`.

Continue the setup on the Data Fabric CLDB node using the [configure.sh](#) on page 3186 script with the HSM parameters, or the [mrhsm Commands](#) on page 975.

Frequently Asked Questions

Answers the frequently asked questions on disaster recovery for KMIP.

1. My client certificate has expired. How do I update it?

- a. You would first need to obtain a new valid, signed client certificate. Follow the instructions from the HSM vendor to update it on the HSM, if needed. For example, Utimaco ESKM requires that you enter the new certificate contents into the [KMIP](#)-enabled local user.
- b. Run the following command:

```
/opt/mapr/server/mrhsm set -clientcert <client_cert.pem> -clientkey
<client_key.pem> -sopin <pin>
```

NOTE: As of March 2025, you can execute the preceding command, only if you have the following patch releases:

- v7.2.0-EBF released on or after 2025-01-28 (patch release 7.2.0.33)
- v7.9.0-EBF released on or after 2025-03-03 (patch release 7.9.0.5)

For any other release versions, Contact HPE Technical Support for help.

2. I forgot my SO PIN. Can I still perform KMIP operations? Can I still make changes to the KMIP configuration?

Keep your SO PIN in a safe place. The SO PIN is not stored in the Data Fabric platform or the HSM. Although you can continue normal operations such as starting the MFS and CLDB without the SO PIN, you would not be able to make any changes to your configuration without it.

If you lose your SO PIN but you want to change some [KMIP](#) configuration settings, you would have to delete your [KMIP](#) token and the `mrhsm.conf` configuration file, that is, everything in the `/opt/mapr/conf/tokens` directory, and then configure the [KMIP](#) settings from scratch, using either the [mrhsm Commands](#) on page 975 or the [configure.sh](#) on page 3186 script. Your CLDB, DARE, Core KEK and Common Master keys are saved in the external HSM, so you would not lose any keys.

3. I accidentally deleted my `/opt/mapr/conf/tokens` directory and I cannot start the CLDB and MFS. How do I recover from this?

The CLDB and DARE keys are stored in the encrypted `/opt/mapr/conf/tokens/mrhsm.conf` file. If you enable HSM functionality, the CLDB and MFS will not be able to start if they cannot find this file. You would need to perform your HSM configuration again from scratch, using either the [mrhsm Commands](#) on page 975 or the [configure.sh](#) on page 3186 script. Your CLDB, DARE, Core KEK and Common Root keys are saved in the external HSM, so you would not lose any keys.

4. I deleted my `/opt/mapr/conf/tokens` directory, and I did not save a copy of my private client key. How do I recover from this?

Once configured, the client private key is stored in encrypted format in the `mrhsm.conf` file and cannot be extracted. You are responsible for keeping a copy of your private client key for disaster recovery purposes. If you deleted your `/opt/mapr/conf/tokens` directory, then, as stated in the previous answer, you would need to perform your HSM configuration again from scratch, and to do this, you would need your client private key.

If you did not save a copy of the client private key, then you would have to follow the instructions in the integration guides ([Utimaco ESKM Integration Guide](#) on page 1000, [Gemalto SafeNet KeySecure Key Manager \(now known as Thales CipherTrust Manager\) Integration Guide](#) on page 1015, or [Vormetric Data Security Manager \(DSM\) Integration Guide](#) on page 1030) to generate the client private key and CSR, and then obtain a new signed client certificate, which may have to be configured into the HSM depending on the vendor.

5. Can I mix and match HSMs from different vendors?

Not within the same Data Fabric cluster. Data Fabric supports multiple HSM vendors, but you can only select one vendor per Data Fabric cluster. HSM vendors normally implement their own clustering solutions, so key propagation to other HSMs in the cluster only works for HSMs from the same vendor. Most HSM vendors recommend a cluster of at least 2 appliances for high reliability and availability purposes. For example, if you choose the Utimaco ESKM, then you would normally configure at least 2 Utimaco ESKM appliances.

6. Can I use different HSM vendors on different clusters, even if there is volume mirroring and table replication between the clusters?

Yes. The HSMs only protect the critical keys within a single Data Fabric cluster, so it is possible to use different HSM vendors for different clusters if there is a good reason to do so. However, this may not be cost-effective as maintaining multiple HSMs from different vendors may result in higher operating costs. HSMs are designed to accommodate multiple keys from different clients.

The Data Fabric [KMIP](#) solution is engineered to generate cluster-specific key names, so there will be no namespace conflict between keys from different clusters.

7. If I initially go for one HSM vendor and store my keys there, can I later migrate to a different HSM vendor?

This is a general migration issue that does not pertain to Data Fabric. Normally, HSMs will be used to store master keys from different applications, of which Data Fabric is one. Migrating to a different HSM vendor will require migrating all the keys from the old HSM vendor to the new one, and involves exporting the [KMIP](#) keys (using the [KMIP](#) Get operation) from the old HSM vendor, and then importing the keys (using the [KMIP](#) Register or Import operation) to the new HSM.

Customers will need to write an application to do this themselves, or engage a professional service provider to do this. After the keys are migrated, follow the steps in the integration guides ([Utimaco ESKM Integration Guide](#) on page 1000, [Gemalto SafeNet KeySecure Key Manager \(now known as Thales CipherTrust Manager\) Integration Guide](#) on page 1015, or [Vormetric Data Security Manager \(DSM\) Integration Guide](#) on page 1030) to configure the new HSM, and use either the [mrhsm Commands](#) on page 975 or the [configure.sh](#) on page 3186 script to set up the Data Fabric CLDB node to work with the new HSM. Then, copy the contents of the `/opt/mapr/conf/tokens` directory to the other CLDB nodes in the cluster. Ensure that all the files in the `/opt/mapr/conf/tokens` directory are owned by the `mapr` user and the `mapr` group.

8. I do not want to use the HSM to store my master keys anymore. However, I already encrypted my disks using DARE, and I do not want to regenerate my Data Fabric tickets. Can I revert to the old file-based solution?

Assuming you did an upgrade from the file-based solution to use the HSM, and you have saved a copy of your `/opt/mapr/conf/cldb.key` and `/opt/mapr/conf/dare.master.key`, the steps to revert are as follows:

- Backup the contents of the `/opt/mapr/conf/tokens` directory, in case you want to go back to the HSM solution.
- Remove the `/opt/mapr/conf/tokens` directory.
- Restore the `/opt/mapr/conf/cldb.key` and the `/opt/mapr/conf/dare.master.key` that you have backed up before you moved to the HSM solution.

9. I do not want to use the HSM to store my master keys anymore, but I do not have backups of `/opt/mapr/conf/cldb.key` and `/opt/mapr/conf/dare.master.key`. Can I still revert to the old file-based solution?

This is not a supported scenario, but you can still do this. Contact HPE Support.

10. I have successfully upgraded from the old file-based solution to use the HSM. Do I still need to backup my `/opt/mapr/conf/cldb.key` and `/opt/mapr/conf/dare.master.key`?

If you have successfully upgraded to use the HSM, then the HSM should contain backups of the CLDB and DARE master keys for disaster recovery purposes. Provided you do not intend to revert to the older (insecure) file-based solution in the future, you can safely delete the `/opt/mapr/conf/cldb.key` and the `/opt/mapr/conf/dare.master.key`.

However, if, for some reason, you feel you may revert from the more secure HSM solution to the less secure file-based solution, you should keep backups of these keys.

11. I am trying to upgrade to use the HSM, but I need time to configure it. Can the Data Fabric platform continue to function while I am testing my configuration?

The HSM functionality will not take effect until you enable it using either the [mrhsm Commands](#) on page 975 or the [configure.sh](#) on page 3186 script. HSM will be enabled only if all settings are correct and all configured HSMs are accessible using the Discover Versions [KMIP](#) operation. If the CLDB or MFS detects that HSM functionality has not been enabled and the `/opt/mapr/conf/cldb.key` and the `/opt/mapr/conf/dare.master.key` exist, it will use those files.

Managing Concurrent User Sessions for User

Describes how to configure or restrict the maximum number of concurrent web server sessions for a Data Fabric user.

Default Behavior

A Data Fabric web UI application, that is, the Data Fabric UI, the Object Store UI, or the Control System, does not impose any restriction on number of concurrent web server sessions for a Data Fabric user. A Data Fabric user can create as many concurrent web server sessions as they wish to, by logging in to a Data Fabric web UI application, using same user credentials, from multiple browsers and/or devices simultaneously, without logging out of any of the applications. There is no restriction on the number of sessions.

Restricting the Maximum Concurrent Web Server Sessions for User

For security purposes, you would want to restrict the maximum number of concurrent web server sessions for a user. For example, you might want to allow only a single web server session for a Data Fabric user at any given point in time.

To restrict the concurrent web server sessions for a Data Fabric user, you must set the `apiserver.max.concurrent.user.sessions` configuration parameter to a non-zero positive integer value. This is a global setting that applies to all Data Fabric users.

IMPORTANT:

- If you wish to restrict the maximum number of concurrent web server sessions permissible for a Data Fabric user, **DO NOT** configure spring security concurrency control in session-management. For example, DO NOT use code similar to the following:

```
<session-management>
  <concurrency-control max-sessions="2" />
</session-management>
```

- If you change the value for the `apiserver.max.concurrent.user.sessions` field when the `apiserver` service is running on your cluster nodes, you must restart the `apiserver` service on all relevant cluster nodes after changing the value for the `apiserver.max.concurrent.user.sessions` field.

Use the [config save](#) on page 2394 command to set the value of `apiserver.max.concurrent.user.sessions`.

For example, to allow only one web server session at a time for a Data Fabric user, set the value of `apiserver.max.concurrent.user.sessions` to 1.

```
maprcli config save -values '{"apiserver.max.concurrent.user.sessions":"1"}'
```

See [config](#) on page 2378 for details on `apiserver.max.concurrent.user.sessions`.

Security for Ecosystem Components

Whether you install Data Fabric software by using the Installer or by using manual steps, the platform and its ecosystem components are installed with security ON by default.

Installer: Security with a Single Click

A single option in the [Installer](#) controls security for the platform and ecosystem components. The **Enable MapR Secure Cluster** option is checked by default for new installations.

Before starting a new installation, if you want to disable security for the platform and ecosystem components, you can deselect the **Enable MapR Secure Cluster** option. Later, after the cluster is installed, if you want to add or remove security, you can select or deselect the option during an **Incremental Install** operation. For more information, see [Enable Data Fabric Secure Cluster](#).

NOTE: Note that some [exceptions to secure by default](#) can require manual intervention. Also, before enabling security using the Incremental Install function, be sure to review the known issue (IN-1084) related to custom certificates. See [Installer Known Issues](#).

Manual Installation: Security with `configure.sh`

When you install a Data Fabric cluster by using the [manual steps](#), you configure security on all nodes by using the `configure.sh` script with the `-secure -genkeys` [options](#), as described in [Enabling Security on a New Cluster Installation](#) on page 250.

Manual installation also creates a cluster that is *secure by default*. For individual ecosystem components, additional security measures are supported, depending on the component. See the notes in the following table.

Security and Ecosystem Components

The Data Fabric platform and the majority of ecosystem components are installed to be secure by default (with some exceptions). The following table lists the EEP 6.0.0 ecosystem components that are secure by default when installed using the Installer or manual installation steps.

Component	Supports Secure by Default	Notes
AsynchHBase	N/A	Security is not applicable. This component acts as a library.
Data Access Gateway 2.0	Yes	For more information, see Understanding the HPE Data Fabric Data Access Gateway on page 1098.
Drill	Yes	For more information about Drill security, see Securing Drill on page 4776.
HBase	Yes	For more information, see HBase Configuration Properties on page 4916.
HBase REST / Thrift Gateway	Yes	For more information, see HBase REST Gateway and HBase Thrift Gateway Secured By Default to Use SSL on page 4932.
Hive	Yes	For more information, see Hive Security on page 4958.
Httpfs	Yes	For more information, see Configuring HttpFS on page 5156.
Hue	Yes	For more information, see Configure Hue with Security on page 5177.
Kafka-Connect	Yes	For more information, see Worker Configuration on page 5299.
Kafka-REST	Yes	For more information, see User Impersonation on page 5261 and SSL Security Configuration on page 5260.

Component	Supports Secure by Default	Notes
KSQL	Yes	For more information, see KSQL Security on page 5228.
Kafka Streams	No	For more information, see Kafka Streams Security on page 5251.
Livy	Yes	For more information, see Configure Livy on page 5223.
Data Fabric Installer	Yes	For more information, see Using the Enable MapR Secure Cluster Option and Using the Enable MapR DARE Option .
Pig	N/A	Security is not applicable. This component acts as a library.
Schema Registry	Yes	For more information, see Security Parameters on page 5336.
Sentry	No	This component can be configured to run on a secure Data Fabric cluster. Security must be configured manually.
Spark	Yes	For more information, see Spark configure.sh on page 5429.
Sqoop 1	N/A	Security is not applicable. This component acts as a library.
Timeline Server	Yes	For more information, see Configuring the Timeline Server to Use the Hive-on-Tez User Interface on page 5046.
Data Fabric Monitoring Components		
collectd	Yes	Communicates over Data Fabric streams. See Spyglass on Streams on page 1962.
ElasticSearch	Yes	For additional steps that you can take to enhance security, see Security Exceptions on page 1093.
FluentD	Yes	For additional steps that you can take to enhance security, see Security Exceptions on page 1093.
Grafana	Yes	For additional steps that you can take to enhance security, see Security Exceptions on page 1093.
Kibana	Yes	For additional steps that you can take to enhance security, see Security Exceptions on page 1093.
OpenTSDB	Yes	Communicates over Data Fabric streams. See Spyglass on Streams on page 1962.

Setting Server Side Timeout for Session Management

Describes how to configure server side timeout to automatically log a Data Fabric user out of an inactive user session in the Data Fabric Web UI application (Control System UI, the Object Store UI or the Data Fabric UI).

IMPORTANT: The value of `session-timeout` in `/opt/mapr/apiserver/conf/web.xml` is specified in minutes, whereas the value of `time-to-live-seconds` and `max-idle-seconds` in `/opt/mapr/apiserver/conf/hazelcast.xml` are specified in seconds. The Data Fabric web server side timeout will work only if following variables are set to the same value (the value must be the same when a common unit of measurement is considered for all the tags in the relevant xml files).

To enable the automatic logout of a user during an inactive session for session timeout management of the Control System, the Object Store UI or the Data Fabric UI, you must set the following tags to the same value.

- Server time out value in `web.xml` (`session-timeout` tag in `/opt/mapr/apiserver/conf/web.xml`)
- Server time out value in `hazelcast.xml` (`time-to-live-seconds` and `max-idle-seconds` tags in `/opt/mapr/apiserver/conf/hazelcast.xml`)
- If SSO is enabled, the timeout value is set in SSO service provider realm (SSO Session Idle) for the SSO user. This value should be two minutes less compared to `session-timeout` value in `web.xml`. See [Keycloak Server Administration Guide](#) for more information. Additionally, the value of the `Access Token Lifespan` variable on Keycloak must be less than the value of the `SSO Session Idle` variable on Keycloak.
-  **NOTE:** A user session becomes inactive only when web browser tab or window running the Data Fabric UI web application is closed.

Example

For example, to initiate an auto-logout of a user after an inactive session of 5 minutes, do the following:

1. In `/opt/mapr/apiserver/conf/web.xml`, set the `session-timeout` as 5 minutes.
`<session-timeout>5</session-timeout>`
2. In `/opt/mapr/apiserver/conf/hazelcast.xml`, set the `time-to-live-seconds` as 300 seconds.

```
<time-to-live-seconds>300</time-to-live-seconds>
|
<max-idle-seconds>300</max-idle-seconds>
```

3. If SSO is enabled, the `SSO Session Idle` value be set to 3 minutes in the SSO service provider realm for the SSO user. The `Access Token Lifespan` could be 1 minute.

Once this is done, a user is logged out automatically from the Control System, the Object Store UI or the Data Fabric UI, when the user session is inactive for a the specified time.

Security Settings for Ecosystem Components

Lists the security settings for all HPE Data Fabric ecosystem components.

The security settings for the various ecosystem components are as follows:

Security Settings for Hadoop/Yarn

File or command: `core-default.xml`

Description: Authentication used for the HTTP web-consoles

	<p><i>Default Secure Setting:</i> <code>hadoop.http.authentication.type:org.apache.hadoop.security.authentication.server.MultiMechsAuthenticationHandler</code></p> <p><i>Alternate Value or Change Command:</i> <code>simple kerberos #AUTHENTICATION_HANDLER_CLASSNAME#</code></p> <p><i>Notes:</i> None</p>
File or command: <code>core-default.xml</code>	<p><i>Description:</i> Custom principal of the service</p> <p><i>Default Secure Setting:</i> <code>hadoop.security.custom.auth.principal.class:com.mapr.security.MapRPrincipal</code></p> <p><i>Alternate Value or Change Command:</i> None</p> <p><i>Notes:</i> None</p>
File or command: <code>core-default.xml & core-site.xml</code>	<p><i>Description:</i> LDAP Configuration</p> <p><i>Default Secure Setting:</i> <code>hadoop.security.group.mapping.ldap.search.filter.user:(&(objectClass=user)(sAMAccountName={0}))</code></p> <p><i>Alternate Value or Change Command:</i> None</p> <p><i>Notes:</i> An additional filter to use when searching for LDAP users. The default filter is usually appropriate for Active Directory installations. If connecting to an LDAP server with a non-AD schema, replace the default filter with <code>(&(objectClass=inetOrgPerson)(uid={0}))</code>. {0} is a special string used to denote where the username fits into the filter. If the LDAP server supports posixGroups, Hadoop can enable the feature by setting the value of this property to <code>posixAccount</code> and the value of the <code>hadoop.security.group.mapping.ldap.search.filter.group</code> property to <code>posixGroup</code>.</p>
File or command: <code>core-default.xml & core-site.xml</code>	<p><i>Description:</i> Client authentication types</p> <p><i>Default Secure Setting:</i> <code>hadoop.security.authentication: CUSTOM</code></p> <p><i>Alternate Value or Change Command:</i> None</p> <p><i>Notes:</i> None.</p>
File or command: <code>core-default.xml & core-site.xml</code>	<p><i>Description:</i> Java class that handles HTTP auth secret</p> <p><i>Default Secure Setting:</i> <code>hadoop.http.authentication.signature.secret:com.mapr.security.maprauth.MaprSignatureSecretFactory</code></p> <p><i>Alternate Value or Change Command:</i> None</p> <p><i>Notes:</i> None.</p>
File or command: <code>core-default.xml & core-site.xml</code>	<p><i>Description:</i> Group authentication cache duration</p> <p><i>Default Secure Setting:</i> <code>hadoop.security.groups.cache.secs:300</code></p> <p><i>Alternate Value or Change Command:</i> None</p> <p><i>Notes:</i> None.</p>
File or command: <code>core-default.xml & core-site.xml</code>	<p><i>Description:</i> Name of the <code>SignerSecretProvider</code> class to use</p>

	<p><i>Default Secure Setting:</i> <code>hadoop.http.authentication.signer.secret.provider:org.apache.hadoop.security.authentication.util.MapRSignerSecretProvider</code></p> <p><i>Alternate Value or Change Command:</i> None</p> <p><i>Notes:</i> None.</p>
File or command: <code>core-default.xml & core-site.xml</code>	<p><i>Description:</i> Service that manages the HPE Data Fabric ticket</p> <p><i>Default Secure Setting:</i> <code>yarn.external.token.manager:com.mapr.hadoop.yarn.security.MapRTicketManager</code></p> <p><i>Alternate Value or Change Command:</i> None</p> <p><i>Notes:</i> None.</p>
File or command: <code>core-default.xml & core-site.xml</code>	<p><i>Description:</i> OS security random device file path</p> <p><i>Default Secure Setting:</i> <code>hadoop.security.random.device.file.path:/dev/urandom</code></p> <p><i>Alternate Value or Change Command:</i> None</p> <p><i>Notes:</i> None.</p>
File or command: <code>core-default.xml & core-site.xml</code>	<p><i>Description:</i> Key to set if the registry is secure</p> <p><i>Default Secure Setting:</i> <code>hadoop.registry.secure:false</code></p> <p><i>Alternate Value or Change Command:</i> <code>true</code></p> <p><i>Notes:</i> Turning it on, changes the permissions policy from open access to restrictions on kerberos with the option of a user adding one or more auth key pairs down their own tree.</p>
File or command: <code>core-default.xml & core-site.xml</code>	<p><i>Description:</i> Authentication class name</p> <p><i>Default Secure Setting:</i> <code>hadoop.log.level.authenticator.class:com.mapr.security.maprauth.MaprAuthenticator</code></p> <p><i>Alternate Value or Change Command:</i> None</p> <p><i>Notes:</i> None</p>
File or command: <code>core-default.xml & core-site.xml</code>	<p><i>Description:</i> Indicates if administrator ACLs are required to access instrumentation servlets (JMX, METRICS, CONF, STACKS)</p> <p><i>Default Secure Setting:</i> <code>hadoop.security.instrumentation.requires.admin:false</code></p> <p><i>Alternate Value or Change Command:</i> <code>true</code></p> <p><i>Notes:</i> None</p>
File or command: <code>core-default.xml & core-site.xml</code>	<p><i>Description:</i> The keystores factory to use for retrieving certificates</p> <p><i>Default Secure Setting:</i> <code>hadoop.ssl.keystores.factory.class:org.apache.hadoop.security.ssl.FileBasedKeyStoresFactory</code></p> <p><i>Alternate Value or Change Command:</i> None</p> <p><i>Notes:</i> None</p>

File or command: `core-default.xml` & `core-site.xml`

Description: Comma-separated list of crypto codec implementations for AES/CTR/NoPadding

Default Secure Setting:

`hadoop.security.crypto.codec.classes.aes.ctr.nopadding:org.apache.hadoop.crypto.OpenSSLAesCtrCryptoCodec,org.apache.hadoop.crypto.JceAesCtrCryptoCodec`

Alternate Value or Change Command: None

Notes: None

File or command: `core-default.xml` & `core-site.xml`

Description: The attribute of the group object that identifies the users that are members of the group.

Default Secure Setting:

`hadoop.security.group.mapping.ldap.search.attr.member:member`

Alternate Value or Change Command: None

Notes: None

File or command: `core-default.xml` & `core-site.xml`

Description: Logs a warning message, if looking up a single user to group takes longer than the specified number of milliseconds

Default Secure Setting:

`hadoop.security.groups.cache.warn.after.ms:5000`

Alternate Value or Change Command: None

Notes: None

File or command: `core-default.xml` & `core-site.xml`

Description: The attribute applied to the LDAP Search Control properties to set a maximum time limit when searching and waiting for a result

Default Secure Setting:

`hadoop.security.group.mapping.ldap.directory.search.timeout:10000`

Alternate Value or Change Command: The unit is in milliseconds. Set to 0 if an infinite wait period is desired. Default is 10 seconds.

Notes: None

File or command: `core-site.xml`

Description: HPE Data Fabric service account ("mapr") impersonation

Default Secure Setting:

- `hadoop.proxyuser.mapr.hosts:*`
- `hadoop.proxyuser.mapr.groups:*`

Alternate Value or Change Command: None

Notes: Set by default in version 6.1 secure install.

File or command: `yarn-site.xml`

Description: Defines the authentication used for the timeline server HTTP endpoint.

Default Secure Setting:

`yarn.timeline-service.http-authentication.type:com.mapr.security.maprauth.MaprDelegationTokenAuthenticationHandler`

Alternate Value or Change Command: Supported values are:

```
simple / kerberos /
#AUTHENTICATION_HANDLER_CLASSNAME
# Defaults to simple.
```

Notes: None.

File or command: `yarn-default.xml`

Description: The allowed pattern for UNIX user names enforced by the Linux-container-executor when used in Nonsecure mode (use case for this is using cgroups).

Default Secure Setting:

```
yarn.nodemanager.linux-container-executor.nonsecure-mode.user-pattern:^([_A-Za-z0-9][-@_.A-Za-z0-9]{0,255}?[$]?$
```

Alternate Value or Change Command: None

Notes: The default value is taken from `/usr/sbin/adduser`.

File or command: `core-default.xml` & `core-site.xml`

Description: Indicates whether or not to use SSL when connecting to the LDAP server.

Default Secure Setting:

```
hadoop.security.group.mapping.ldap.ssl:false
```

Alternate Value or Change Command: true

Notes: None

File or command: `core-default.xml` & `core-site.xml`

Description: An additional filter to use when searching for LDAP groups

Default Secure Setting:

```
hadoop.security.group.mapping.ldap.search.filter.group:(objectClass=group)
```

Alternate Value or Change Command: None

Notes: Change this filter when resolving groups against a non-Active Directory installation. See the description of `hadoop.security.group.mapping.ldap.search.filter.user` to enable posixGroups support.

File or command: `core-default.xml` & `core-site.xml`

Description: This setting is the configuration controlling the validity of the entries in the cache containing the `userId` to `userName` and `groupId` to `groupName` mappings that are used by `NativeIO` `getFstat()`.

Default Secure Setting:

```
hadoop.security.uid.cache.secs:14400
```

Alternate Value or Change Command: None

*Notes:*None

File or command: `yarn-default.xml`

Description: Determines which of the two modes LCE should use on a nonsecure cluster.

Default Secure Setting:

```
yarn.nodemanager.linux-container-executor.nonsecure-mode.limit-users:true
```

Alternate Value or Change Command: false

*Notes:*Set this value to true, to launch all containers as the user specified in

yarn.nodemanager.linux-container-executor.nonsecure-mode.local-user. Set this value to false to run containers as the user who submitted the application.

File or command: yarn-default.xml

Description: Disable insecure protocols

Default Secure Setting:

```
hadoop.ssl.exclude.insecure.protocols:
SSLv3, TLSv1, TLSv1.1
```

Alternate Value or Change Command: None

Notes: None

File or command: core-default.xml & core-site.xml

Description: Class for user to group mapping (get groups for a given user) for ACL.

Default Secure Setting:

```
hadoop.security.group.mapping:org.apache
.hadoop.security.JniBasedUnixGroupsMappingWithFallback
```

Alternate Value or Change Command: None

Notes: The default implementation org.apache.hadoop.security.JniBasedUnixGroupsMappingWithFallback determines if the Java Native Interface (JNI) is available. If JNI is available, the implementation uses the API within Hadoop to resolve a list of groups for a user. If JNI is not available, then the shell implementation ShellBasedUnixGroupsMapping, is used. This implementation shells out to the Linux/Unix environment with the bash -c groups command to resolve a list of groups for a user.

File or command: core-default.xml & core-site.xml

Description: Class for the 'custom type of authentication' method

Default Secure Setting:

```
hadoop.security.custom.rpc.auth.method:
class:org.apache.hadoop.security.rpcauth.
MaprAuthMethod
```

Alternate Value or Change Command: None

Notes: None

File or command: core-default.xml & core-site.xml

Description: The attribute of the group object that identifies the group name

Default Secure Setting:

```
hadoop.security.group.mapping.ldap.search.attr.group.name:cn
```

Alternate Value or Change Command: None

Notes: The default setting is usually appropriate for all LDAP systems.

File or command: core-default.xml & core-site.xml

Description: The Java secure random algorithm.

Default Secure Setting:

```
hadoop.security.java.secure.random.algorithm:SHA1PRNG
```

Alternate Value or Change Command: None

Notes: None

File or command: `core-default.xml` & `core-site.xml`

Description: Indicates whether service-level authorization is enabled

Default Secure Setting:
`hadoop.security.authorization:true`

Alternate Value or Change Command: `false`

Notes: None

File or command: `core-default.xml` & `core-site.xml`

Description: Expiration time for entries in the the negative user-to-group mapping caching, in seconds

Default Secure Setting:
`hadoop.security.groups.negative-cache.seconds:30`

Alternate Value or Change Command: `None`

Notes: This setting is useful when invalid users retry frequently. Set a low value for this expiration, since a transient error in group lookup could temporarily lock out a legitimate user. Set this parameter to zero or a negative value, to disable negative user-to-group caching.

File or command: `yarn-default.xml`

Description: Linux-container-executor setting

Default Secure Setting:
`yarn.nodemanager.linux-container-executor.nonsecure-mode.local-user:nobody`

Alternate Value or Change Command: `None`

Notes: The UNIX user that containers run as when Linux-container-executor is used in Nonsecure mode (a use case for this is using cgroups) if the `yarn.nodemanager.linux-container-executor.nonsecure-mode.limit-users` is set to `true`.

File or command: `core-default.xml` & `core-site.xml`

Description: Cipher suite for crypto codec.

Default Secure Setting:
`hadoop.security.crypto.cipher.suite:AES/CTR/NoPadding`

Alternate Value or Change Command: `None`

Notes: None

File or command: `core-default.xml` & `core-site.xml`

Description: Denotes the buffer size used by `CryptoInputStream` and `CryptoOutputStream`.

Default Secure Setting:
`hadoop.security.crypto.buffer.size:8192`

Alternate Value or Change Command: `None`

Notes: None

File or command: `core-default.xml` & `core-site.xml`

Description: Path to the JAAS configuration file

Default Secure Setting:
`hadoop.security.java.security.login.config.jar.path:/mapr.login.conf`

Alternate Value or Change Command: `None`

Notes: None

File or command: `core-default.xml` & `core-site.xml`

Description: Indicates if anonymous requests are allowed when using simple authentication.

	<p><i>Default Secure Setting:</i> hadoop.http.authentication.simple.anonymous.allowed:true</p> <p><i>Alternate Value or Change Command:</i> false</p> <p><i>Notes:</i> None</p>
File or command: yarn-default.xml	<p><i>Description:</i> Indicates if anonymous requests are allowed by the timeline server when using simple authentication.</p> <p><i>Default Secure Setting:</i> yarn.timeline-service.http-authentication.simple.anonymous.allowed:true</p> <p><i>Alternate Value or Change Command:</i> false</p> <p><i>Notes:</i> None</p>
File or command: core-default.xml & core-site.xml	<p><i>Description:</i> Indicates how long (in seconds) an authentication token is valid before it has to be renewed.</p> <p><i>Default Secure Setting:</i> hadoop.http.authentication.token.validity:36000</p> <p><i>Alternate Value or Change Command:</i> None</p> <p><i>Notes:</i> None</p>
File or command: core-default.xml & core-site.xml	<p><i>Description:</i> IPC client fallback.</p> <p><i>Default Secure Setting:</i> ipc.client.fallback-to-simple-auth-allowed:false</p> <p><i>Alternate Value or Change Command:</i> true</p> <p><i>Notes:</i> When a client is configured to attempt a secure connection, but attempts to connect to an insecure server, that server may instruct the client to switch to SASL SIMPLE (unsecure) authentication. This setting controls whether or not the client accepts this instruction from the server. When false (the default), the client does not allow the fallback to SIMPLE authentication, but aborts the connection.</p>
File or command: yarn-default.xml	<p><i>Description:</i> Initial duration of the Data Fabric ticket</p> <p><i>Default Secure Setting:</i> yarn.mapr.ticket.expiration:604800000</p> <p><i>Alternate Value or Change Command:</i> None</p> <p><i>Notes:</i> None</p>
File or command: core-default.xml & core-site.xml	<p><i>Description:</i> Protocols supported by SSL.</p> <p><i>Default Secure Setting:</i> hadoop.ssl.enabled.protocols:TLSv1.2</p> <p><i>Alternate Value or Change Command:</i> true</p> <p><i>Notes:</i> When a client is configured to attempt a secure connection, but attempts to connect to an insecure server, that server may instruct the client to switch to SASL SIMPLE (unsecure) authentication. This setting controls whether or not the client accepts this instruction from the server. When false (the default), the client does not allow the fallback to SIMPLE authentication, but aborts the connection.</p>

File or command: `core-default.xml` &
`core-site.xml`

Description: List of excluded ciphers

Default Secure Setting:

`hadoop.ssl.exclude.cipher.suites:SSL_DHE_RSA_EXPORT_WITH_DES40_CBC_SHA,SSL_RSA_EXPORT_WITH_DES40_CBC_SHA,SSL_RSA_EXPORT_WITH_RC4_40_MD5,TLS_DHE_RSA_WITH_AES_128_CBC_SHA,TLS_DHE_RSA_WITH_AES_256_CBC_SHA,TLS_DHE_RSA_WITH_AES_256_CBC_SHA256,TLS_DHE_DSS_WITH_AES_256_CBC_SHA256,TLS_DHE_DSS_WITH_AES_256_CBC_SHA,TLS_DHE_RSA_WITH_AES_128_CBC_SHA256,TLS_DHE_DSS_WITH_AES_128_CBC_SHA256,TLS_DHE_DSS_WITH_AES_128_CBC_SHA`

Alternate Value or Change Command: None

Notes: None

File or command: `core-default.xml` &
`core-site.xml`

Description: Indicates whether client certificates are required

Default Secure Setting:

`hadoop.ssl.require.client.cert:false`

Alternate Value or Change Command: true

Notes: None

File or command: `core-default.xml` &
`core-site.xml`

Description: The hostname verifier to provide for `HttpsURLConnections`

Default Secure Setting:

`hadoop.ssl.hostname.verifier:DEFAULT`

Alternate Value or Change Command: Valid values are: `DEFAULT`, `STRICT`, `STRICT_I6`, `DEFAULT_AND_LOCALHOST`, and `ALLOW_ALL`

Notes: None

File or command: `core-default.xml` &
`core-site.xml`

Description: Resource file from which SSL client keystore information is extracted

Default Secure Setting:

`hadoop.ssl.client.conf:ssl-client.xml`

Alternate Value or Change Command: None

Notes: This file is looked up in the classpath, and is usually present in the Hadoop `conf/` directory.

File or command: `mapred-default.xml`

Description: Buffer size for reading spills from file when using SSL.

Default Secure Setting:

`mapreduce.shuffle.ssl.file.buffer.size:65536`

Alternate Value or Change Command: None

Notes: None

File or command: `core-default.xml` &
`core-site.xml`

Description: The keystores factory to use for retrieving certificates.

Default Secure Setting:

`hadoop.ssl.keystores.factory.class:org.apache.hadoop.security.ssl.FileBasedKeyStoresFactory`

Alternate Value or Change Command: None

	<p><i>Notes:</i> None</p>
<p>File or command: <code>core-default.xml</code> & <code>core-site.xml</code></p>	<p><i>Description:</i> Comma-separated list of crypto codec implementations for AES/CTR/NoPadding.</p> <p><i>Default Secure Setting:</i> <code>hadoop.security.crypto.codec.classes.aes.ctr.nopadding:</code> <code>org.apache.hadoop.crypto.OpenSSLAESCTRCryptoCodec,org.apache.hadoop.crypto.JceAESCTRCryptoCodec</code></p> <p><i>Alternate Value or Change Command:</i> None</p> <p><i>Notes:</i> The first implementation is used, if available. Other implementations are fallbacks.</p>
<p>File or command: <code>core-default.xml</code> & <code>core-site.xml</code></p>	<p><i>Description:</i> Resource file from which SSL server keystore information is extracted.</p> <p><i>Default Secure Setting:</i> <code>hadoop.ssl.server.conf:ssl-server.xml</code></p> <p><i>Alternate Value or Change Command:</i> None</p> <p><i>Notes:</i> This file is looked up in the classpath, and is usually present in the Hadoop conf/ directory.</p>
<p>File or command: <code>core-default.xml</code> & <code>core-site.xml</code></p>	<p><i>Description:</i> Configures the HTTP endpoint for Yarn daemons.</p> <p><i>Default Secure Setting:</i> <code>yarn.http.policy:HTTP_ONLY</code></p> <p><i>Alternate Value or Change Command:</i> The following values are supported:</p> <ul style="list-style-type: none"> • <code>HTTP_ONLY</code>: Service is provided only on HTTP • <code>HTTPS_ONLY</code>: Service is provided only on HTTPS <p><i>Notes:</i> None.</p>
<p>File or command: <code>core-default.xml</code> & <code>core-site.xml</code></p>	<p><i>Description:</i> Indicates whether or not to use SSL when connecting to the LDAP server.</p> <p><i>Default Secure Setting:</i> <code>hadoop.security.group.mapping.ldap.ssl:false</code></p> <p><i>Alternate Value or Change Command:</i> None</p> <p><i>Notes:</i> None.</p>
<p>File or command: <code>core-default.xml</code> & <code>core-site.xml</code></p>	<p><i>Description:</i> Enables or disables SSL connections to S3.</p> <p><i>Default Secure Setting:</i> <code>fs.s3a.connection.ssl.enabled:true</code></p> <p><i>Alternate Value or Change Command:</i> <code>false</code></p> <p><i>Notes:</i> None.</p>
<p>File or command: <code>mapred-default.xml</code></p>	<p><i>Description:</i> Indicates whether to use SSL for for the Shuffle HTTP endpoints.</p> <p><i>Default Secure Setting:</i> <code>mapreduce.shuffle.ssl.enabled:false</code></p> <p><i>Alternate Value or Change Command:</i> <code>true</code></p> <p><i>Notes:</i> None.</p>

Security Settings for Hive**File or command:** `hive-site.xml`*Description:* Hive client authenticator manager class name*Default Secure Setting:*`hive.security.authenticator.manager:org.apache.hadoop.hive.ql.security.HadoopDefaultAuthenticator`*Alternate Value or Change Command:* None*Notes:* None.**File or command:** `hive-site.xml`*Description:* Enables or disables Hive client authorization*Default Secure Setting:*`hive.security.authorization.enabled:true`*Alternate Value or Change Command:* false*Notes:* None.**File or command:** `hive-site.xml`*Description:* The Hive client authorization manager class name*Default Secure Setting:*`hive.security.authorization.manager:org.apache.hadoop.hive.ql.security.authorization.plugin.fallback.FallbackHiveAuthorizerFactory`*Alternate Value or Change Command:* None*Notes:* None.**File or command:** `hive-site.xml`*Description:* List of comma separated Java regexes*Default Secure Setting:*`hive.security.authorization.sqlstd.confwhitelist:hive\.exec\.pre\.hooks`*Alternate Value or Change Command:* None*Notes:* You can modify configurations parameters that match these regexes when you enable SQL standard authorization.**File or command:** `hive-site.xml`*Description:* Authorization DDL task factory implementation*Default Secure Setting:*`hive.security.authorization.task.factory:org.apache.hadoop.hive.ql.parse.authorization.HiveAuthorizationTaskFactoryImpl`*Alternate Value or Change Command:* None*Notes:* None**File or command:** `hive-site.xml`*Description:* Comma-separated list of non-SQL Hive commands that users are authorized to execute*Default Secure Setting:*`hive.security.command.whitelist:set,reset,dfs,add,list,delete,reload,compile`*Alternate Value or Change Command:* None*Notes:* None**File or command:** `hive-site.xml`*Description:* Authenticator manager class name to be used in the metastore for authentication.

	<p><i>Default Secure Setting:</i> hive.security.metastore.authenticator.manager:org.apache.hadoop.hive.ql.security.HadoopDefaultMetastoreAuthenticator</p> <p><i>Alternate Value or Change Command:</i> None</p> <p><i>Notes:</i> None</p>
File or command: hive-site.xml	<p><i>Description:</i> When set to true, the metastore authorizer authorizes read actions on the database and table</p> <p><i>Default Secure Setting:</i> hive.security.metastore.authorization.auth.reads:true</p> <p><i>Alternate Value or Change Command:</i> false</p> <p><i>Notes:</i> None</p>
File or command: hive-site.xml	<p><i>Description:</i> Names of authorization manager classes (comma-separated) to be used in the metastore for authorization.</p> <p><i>Default Secure Setting:</i> hive.security.metastore.authorization.manager:org.apache.hadoop.hive.ql.security.authorization.StorageBasedAuthorizationProvider</p> <p><i>Alternate Value or Change Command:</i> None</p> <p><i>Notes:</i> The user defined authorization class should implement interface org.apache.hadoop.hive.ql.security.authorization.HiveMetastoreAuthorizationProvider. All authorization manager classes have to successfully authorize the metastore API call for the command execution to be allowed.</p>
File or command: hive-site.xml	<p><i>Description:</i> If true, the HiveServer2 WebUI is secured with PAM</p> <p><i>Default Secure Setting:</i> hive.server2.webui.use.pam=true</p> <p><i>Alternate Value or Change Command:</i> false</p> <p><i>Notes:</i> None</p>
File or command: hive-site.xml	<p><i>Description:</i> Class for PAM authentication</p> <p><i>Default Secure Setting:</i> hive.server2.webui.pam.authenticator:org.apache.hive.http.security.PamAuthenticator</p> <p><i>Alternate Value or Change Command:</i> None</p> <p><i>Notes:</i> None</p>
File or command: hive-site.xml	<p><i>Description:</i> Determines whether the metastore performs authorization checks against the underlying storage for operations such as drop-partition</p> <p><i>Default Secure Setting:</i> hive.metastore.authorization.storage.check.externaltable.drop:true</p> <p><i>Alternate Value or Change Command:</i> false</p>

File or command: `hive-site.xml`

Notes: Disallow the drop-partition if the user in question does not have permissions to delete the corresponding directory on the storage

Description: Determines whether the metastore performs authorization checks against the underlying storage for operations such as drop-partition

Default Secure Setting:
`hive.metastore.authorization.storage.checks>false`

Alternate Value or Change Command: `true`

Notes: Disallow the drop-partition if the user in question does not have permissions to delete the corresponding directory on the storage

File or command: `hive-site.xml`

Description: Client authentication types.

Default Secure Setting:
`hive.server2.authentication:PAM`

Alternate Value or Change Command:

- NONE: no authentication check – plain SASL transport
- LDAP: LDAP/AD based authentication
- KERBEROS: Kerberos/GSSAPI authentication
- CUSTOM: Custom authentication provider (use with property
`hive.server2.custom.authentication.class`)
- PAM: Pluggable authentication module (added in Hive 0.13.0 with HIVE-6466)
- NOSASL: Raw transport (added in Hive 0.13.0)

Notes: None

File or command: `hive-site.xml`

Description: Use this property in LDAP search queries for finding LDAP group names to which a user belongs

Default Secure Setting:
`hive.server2.authentication.ldap.groupClassKey:groupOfNames`

Alternate Value or Change Command: None

Notes: Use this property to construct a LDAP group search query, and to indicate the `objectClass` of a group. Every LDAP group has a certain `objectClass`. For example: `group`, `groupOfNames`, and `groupOfUniqueNames`.

File or command: `hive-site.xml`

Description: LDAP attribute name on the group object that contains the list of distinguished names for the user, group, and contact objects that are members of the group.

Default Secure Setting:
`hive.server2.authentication.ldap.groupMembershipKey:member`

Alternate Value or Change Command: None

Notes: For example: member, uniqueMember, or memberUid. Use this property in LDAP search queries when finding LDAP group names to which a particular user belongs. The value of the LDAP attribute as indicated by this property, should be a full DN for the user or the short username or userid.

For example, a group entry for fooGroup containing member : uid=fooUser,ou=Users,dc=domain,dc=com helps determine that fooUser belongs to LDAP group fooGroup.

See Group Membership for a detailed example. You can use this property to find the users, if a custom-configured LDAP query returns a group instead of a user (as of Hive 2.1.1). For details, see Support for Groups in Custom LDAP Query.

File or command: hive-site.xml

Description: This property indicates the prefix to use when building the bindDN for LDAP connection (when using only baseDN).

Default Secure Setting:
hive.server2.authentication.ldap.guidKey:uid

Alternate Value or Change Command: None

Notes: bindDN is <guidKey>=<user/group>, <baseDN>. If the configuration uses userDNPattern and/or groupDNPattern, the guidKey is not required. The guidKey is required when only the baseDN is being used.

File or command: hive-site.xml

Description: When true, HiveServer2 in HTTP transport mode uses a cookie-based authentication mechanism.

Default Secure Setting:
hive.server2.thrift.http.cookie.auth.enabled:true

Alternate Value or Change Command: None

Notes: None

File or command: hive-site.xml

Description: Sasl QOP value; set it to one of the following values to enable higher levels of protection for HiveServer2 communication with clients.

Default Secure Setting:
hive.server2.thrift.sasl.qop:auth-conf

Alternate Value or Change Command: One of:

- auth – authentication only (default)
- auth-int – authentication plus integrity protection
- integrity protection auth-conf – authentication plus integrity and confidentiality protection

Notes: Note that setting hadoop.rpc.protection to a higher level than HiveServer2 does not make sense in most situations. HiveServer2 ignores hadoop.rpc.protection in favor of hive.server2.thrift.sasl.qop. This setting is applicable only if HiveServer2 is configured to use Kerberos authentication.

File or command: hive-site.xml

Description: Applies test settings for HS2 (for example for standard base authorization verification in `FallbackHiveAuthorizer` or in `SQLAuthorizationUtils`).

Default Secure Setting:

`hive.test.authz.sstd.hs2.mode:false`

Alternate Value or Change Command: None

Notes: None

File or command: hive-site.xml

Description: Setting this property to `true` enables `HiveServer2` to execute Hive operations as the user making the calls.

Default Secure Setting:

`hive.server2.enable.doAs=true`

Alternate Value or Change Command: `false`

Notes: None

File or command: hive-site.xml

Description: Indicates whether metastore should use SSL

Default Secure Setting:

`hive.metastore.use.SSL:false`

Alternate Value or Change Command: `false`

Notes: None

File or command: hive-site.xml

Description: SSL certificate keystore location.

Default Secure

Setting: `hive.server2.keystore.path:/opt/mapr/conf/ssl_keystore`

Alternate Value or Change Command: None

Notes: None

File or command: hive-site.xml

Description: Set this to `true` to use SSL encryption in `HiveServer2`.

Default Secure Setting:

`hive.server2.use.SSL:true`

Alternate Value or Change Command: `false`

Notes: None

File or command: hive-site.xml

Description: SSL certificate keystore location for `HiveServer2 WebUI`.

Default Secure Setting:

`hive.server2.webui.keystore.path:/opt/mapr/conf/ssl_keystore`

Alternate Value or Change Command: None

Notes: None

File or command: hive-site.xml

Description: Set this to `true` to use SSL encryption for `HiveServer2 WebUI`.

Default Secure Setting:

`hive.server2.webui.use.ssl:true`

Alternate Value or Change Command: `true`

Notes: None

File or command: hive-site.xml

Description: SSL protocols that need to be disabled

Default Secure Setting:

hive.ssl.protocol.blacklist:SSLv2,SSLv3

Alternate Value or Change Command: None

Notes: None

Security Settings for HTTPFS

File or command: httpfs-site.xml

Description: PAM authentication for HttpFS

Default Secure Setting:

- httpfs.hadoop.authentication.type:multiauth
- httpfs.authentication.type:multiauth

Alternate Value or Change Command: None

Notes: None

File or command: httpfs-site.xml

Description: User impersonation for HttpFS

Default Secure Setting:

- httpfs.proxyuser.mapr.hosts:*
- httpfs.proxyuser.mapr.groups:*

Alternate Value or Change Command: None

Notes: None

Security Settings for Hue

File or command: hue.ini

Description: Configure HTTPS for Hue UI

Default Secure Setting:

```
[desktop]
ssl_certificate=${ssl_certificate}
ssl_private_key=${ssl_private_key}
ssl_password_script=${HUE_HOME}/bin/
ssl_password_script.sh
```

Alternate Value or Change Command: true

Notes: Value is picked from the following files:

```
cat /opt/mapr/hue/hue-4.6.0/desktop/
conf/.isSecure
true

cat /opt/mapr/hue/hue-4.6.0/desktop/
conf/env.d/20secure

HUE_SECURE_FILE="${HUE_HOME}/desktop/
conf/.isSecure"
if [ -e "$HUE_SECURE_FILE" ] && [ $
(cat "$HUE_SECURE_FILE") = "true" ] ;
thee
    export mechanism=$
{mechanism:-"MAPR-SECURITY"}
    export security_enabled=$
{security_enabled:-"true"}
```

```
export ssl_cacerts=${ssl_cacerts:-"${MAPR_HOME}/conf/ssl_truststore.pem"}
export ssl_validate=${ssl_validate:-"true"}
export ssl_certificate=${ssl_certificate:-"${MAPR_HOME}/conf/ssl_keystore.pem"}
export ssl_private_key=${ssl_private_key:-"${MAPR_HOME}/conf/ssl_keystore.pem"}
fi
```

The password for the SSL private key is parsed from the `/opt/mapr/conf/ssl-server.xml` file with the `${HUE_HOME}/bin/ssl_password_script.sh` script.

File or command: `hue.ini`

Description: Path to PEM truststore, and option to enable/disable certificate verification for SSL-encrypted connections to other services (RM, HS, NM, Spark HS, Oozie, Livy, HBase, Hive, Impala)

Default Secure Setting:

```
[desktop]
ssl_cacerts=${ssl_cacerts}
ssl_validate=${ssl_validate}
```

Alternate Value or Change Command: `true`

Notes: Values are picked in the same way, as values for the previous parameter. Also, the installer overrides this property with value `false` by creating the following file:

```
cat /opt/mapr/hue/hue-4.6.0/desktop/conf/env.d/30installer

# Do not edit this file. It
# was generated automatically by MapR
# Installer.
# Disable certificate verification,
# as Installer allows to use node
# IPs instead of proper hostnames:
export ssl_cacerts=""
export ssl_validate="false"
```

File or command: `hue.ini`

Description: Configure Hue to use MapR-SASL for YARN (RM, NM, HS, Spark HS)

Default Secure Setting:

```
[hadoop]
[[yarn_clusters]]
[[[default]]]
# ...
# Change this if your YARN
# cluster is secured
# security_enabled=${security_enabled}
# Security mechanism
# of authentication none/GSSAPI/
```

```
MAPR-SECURITY
# mechanism=${mechanism}
# In secure mode(HTTPS), if SSL
certificates from Resource Manager's
# Rest Server have to be
verified against certificate authority
# ssl_cert_ca_verify=false
```

Alternate Value or Change Command: true

Notes: Value is picked from the following files:

```
cat /opt/mapr/hue/hue-4.6.0/desktop/
conf/.isSecure
true

cat /opt/mapr/hue/hue-4.6.0/desktop/
conf/env.d/20secure
HUE_SECURE_FILE="${HUE_HOME}/desktop/
conf/.isSecure"
if [ -e "$HUE_SECURE_FILE" ] && [ $
(cat "$HUE_SECURE_FILE") = "true" ] ;
then
    export mechanism=$
{mechanism:-"MAPR-SECURITY"}
    export security_enabled=$
{security_enabled:-"true"}
    export ssl_cacerts=${ssl_cacerts:-"$
{MAPR_HOME}/conf/ssl_truststore.pem"}
    export ssl_validate=$
{ssl_validate:-"true"}
    export ssl_certificate=$
{ssl_certificate:-"${MAPR_HOME}/conf/
ssl_keystore.pem"}
    export ssl_private_key=$
{ssl_private_key:-"${MAPR_HOME}/conf/
ssl_keystore.pem"}
fi
```

File or command: hue.ini

Description: Configure Hue to use MapR-SASL for HttpFS

Default Secure Setting:

```
[hadoop]
[[hdfs_clusters]]
[[[default]]]
...
# Change this if your HDFS
cluster is secured
security_enabled=$
{security_enabled}
# Security mechanism
of authentication none/GSSAPI/
MAPR-SECURITY
mechanism=${mechanism}
# Enable mutual SSL
authentication
# mutual_ssl_auth=False
# Certificate for SSL connection
# ssl_cert=keys/cert.pem
# Private key for SSL connection
```

```
# ssl_key=keys/
hue_private_keystore.pem
# In secure mode (HTTPS), if
SSL certificates from YARN Rest APIs
# have to be verified against
certificate authority
## ssl_cert_ca_verify=True
```

Alternate Value or Change Command: true

Notes: Value is picked from the following files:

```
cat /opt/mapr/hue/hue-4.6.0/desktop/
conf/.isSecure
true

cat /opt/mapr/hue/hue-4.6.0/desktop/
conf/env.d/20secure
HUE_SECURE_FILE="${HUE_HOME}/desktop/
conf/.isSecure"
if [ -e "$HUE_SECURE_FILE" ] && [ $
(cat "$HUE_SECURE_FILE") = "true" ] ;
then
    export mechanism=$
{mechanism:-"MAPR-SECURITY"}
    export security_enabled=$
{security_enabled:-"true"}
    export ssl_cacerts=${ssl_cacerts:-"$
{MAPR_HOME}/conf/ssl_truststore.pem"}
    export ssl_validate=$

    # This will be used when
password is required and `password`
is not set.
    # password_script=

```

Alternate Value or Change Command: true

Notes: None

File or command: hue.ini

Description: User impersonation between Hue and YARN services (RM, NM, HS) + Spark HS

Default Secure Setting: Enabled by default

Alternate Value or Change Command: false

Notes: Hue always send requests to RM, NM, HS and SparkHS with the doAs=<impersonation_target> parameter

File or command: hue.ini

Description: User impersonation between Hue and HttpFS

Default Secure Setting: Enabled by default

Alternate Value or Change Command: false

Notes: Hue always send requests to HttpFS with the doAs=<impersonation_target> parameter

File or command: hue.ini

Description: User impersonation between Hue and Oozie

Default Secure Setting: Enabled by default

Alternate Value or Change Command: false

Notes: Hue always send requests to Oozie with the doAs=<impersonation_target> parameter

File or command: hue.ini

Description: User impersonation between Hue and Livy

Default Secure Setting: Enabled by default

Alternate Value or Change Command: false

Notes: Hue always send requests to Livy with the the proxyUser=<impersonation_target> option

File or command: hue.ini

Description: User impersonation between Hue and Hive

Default Secure Setting: true (enabled)

Alternate Value or Change Command: false

File or command: hue.ini

Notes: Hue automatically detects impersonation settings of Hive from hive-site.xml

Description: User impersonation between Hue and HBase Thrift (Data Fabric DB)

Default Secure Setting: false (disabled)

Alternate Value or Change Command: false

Notes: Hue automatically detects impersonation settings of Hive from hbase-site.xml

File or command: hue.ini

Description: User impersonation between Hue and Drill

Default Secure Setting:

```
[librdbsms]
[[databases]]
# ...
[[[drill]]]
# ...
# Available options:
# "impersonation" to enable or
# disable outbound impersonation.
# "principal" of Drill service.
# Used when Kerberos authentication is
# enabled.
options='{ "impersonation":true}
```

Alternate Value or Change Command: true

Notes: None

File or command: hue.ini

Description: Authenticating Hue users with LDAP credentials

Default Secure Setting: TDB

Alternate Value or Change Command: None

Notes: None

File or command: hue.ini

Description: Determines which authentication method to use: search and bind, or direct bind

Default Secure Setting:
search_bind_authentication

Alternate Value or Change Command: None

Notes: When set to true, Hue performs an LDAP search using bind_dn and bind_password as provided in hue.ini. The search can be further limited by the search filter user_filter. When set to false, Hue performs a direct bind to LDAP using the credentials provided from one of these sources:

- The UPN, formed by concatenating <shortname> (the user name provided on the Hue login page) and nt_domain (if nt_domain is specified)
- The ldap_username_pattern (if nt_domain is not specified)

File or command: hue.ini

Description: The NT domain to connect. This parameter is only used with Active Directory.

File or command: `hue.ini`

Default Secure Setting: `nt_domain`

Alternate Value or Change Command: None

Notes: Used with the `direct` bind method of authentication. If `nt_domain` is specified, then `ldap_username_pattern` is ignored.

Description: Used to connect to directory services other than Active Directory.

Default Secure Setting: `ldap_username_pattern`

Alternate Value or Change Command: None

Notes: Used with the `direct` bind method of authentication. Usually takes the form `cn=<username>,dc=example,dc=com`

File or command: `hue.ini`

Description: The backend to use for authenticating users.

Default Secure Setting: `backend`

Alternate Value or Change Command: None

Notes: Set it to `desktop.auth.backend.LdapBackend` for Hue authentication.

File or command: `hue.ini`

Description: Configure Hue with HiveServer2 High Availability

Setting:

```
[beeswax]
#Whether to use service discovery
for llap.
hive_discovery_llap = true
#Is llap (hive server interactive)
running in HA.
hive_discovery_llap_ha = true
#Whether to use service discovery
for HiveServer2.
hive_discovery_hs2 = true
[libzookeeper]
#Zookeeper ensemble;
comma-separated list of host/port.
ensemble=<host:port>:5181
```

Notes: None

Security Settings for Drill

File or command: `drill-override.conf`

Description: Determines if encryption on the server is enabled for negotiating privacy with the Drill client.

Default Secure Setting:
`drill.exec.security.user.encryption.sasl.enabled=false`

Alternate Value or Change Command: `true`

Notes: None.

File or command: `drill-override.conf`

Description: Determines if the server is enabled for negotiating privacy with another Drillbit.

File or command: drill-distrib.conf	<p><i>Description:</i> Zookeeper znode ACL for Drill cluster info and query info</p> <p><i>Default Secure Setting:</i> zk.apply_secure_acl: true</p> <p><i>Alternate Value or Change Command:</i> false</p> <p><i>Notes:</i> Set by default on HPE Data Fabric Secure cluster with installer in drill-distrib.conf. drill.exec.zk.apply_secure_acl: true</p>
File or command: drill-distrib.conf	<p><i>Description:</i> Drill user impersonation, needed for Data Fabric DB to work properly with CF access</p> <p><i>Default Secure Setting:</i> drill.exec.impersonation.enabled: true</p> <p><i>Alternate Value or Change Command:</i> false</p> <p><i>Notes:</i> Set by default on HPE Data Fabric Secure cluster with installer in drill-distrib.conf. drill.exec.impersonation.enabled: true, also see impersonation inbound policies for information on setting which users can impersonate others.</p>

File or command: drill-override.conf

Description: Drill user impersonation, maximum number of hops - when one user creates a view on data and shares with other, how many hops are allowed

Default Secure Setting:
drill.exec.impersonation.max_chained_user_hops: 3

Alternate Value or Change Command: Other numeric values

Notes: Set by default on HPE Data Fabric Secure cluster with installer in drill-distrib.conf.

File or command: drill-override.conf

Description: Authentication mechanisms

Default Secure Setting:
drill.exec.security.auth.mechanisms: ["MAPRSASL", "PLAIN"]

Alternate Value or Change Command: KERBEROS

Notes: Set by default on HPE Data Fabric Secure cluster with installer in drill-distrib.conf.

File or command: drill-override.conf

Description: End user encryption mechanism

Default Secure Setting:
drill.exec.security.user.encryption.sasl.enabled: true

Alternate Value or Change Command: Can set drill.exec.security.user.encryption.ssl.enabled: true

Notes: Set by default on HPE Data Fabric Secure cluster with installer in drill-distrib.conf.

To use SSL, set
drill.exec.security.user.encryption.ssl.enabled: true.

To use PLAIN (user/pass) authentication, SASL encryption cannot be set to true. You have to set SSL encryption to use PLAIN authentication. You can also use HPE Data Fabric tickets (SASL) with SSL encryption, but only with SSL encryption for both.

Security Settings for Spark**File or command: spark-defaults.conf**

Description: SSL option for file download client (used to download jars and files from HTTPS-enabled servers).

Default Secure Setting: spark.ssl.fs.enabled true

Alternate Value or Change Command: <https://spark.apache.org/docs/2.3.1/security.html>

Notes: None

File or command: spark-defaults.conf

Description: The password to the private key in the key store.

Default Secure Setting: spark.ssl.keyPassword <ssl-keystore-password>

Alternate Value or Change Command: None

Notes: None

File or command: spark-defaults.conf

Description: Path to the key store file. The path can be absolute or relative to the directory in which the process is started.

Default Secure Setting:

· spark.ssl.keyStore /opt/mapr/conf/ssl_keystore

Alternate Value or Change Command: None

Notes: None

File or command: spark-defaults.conf

Description: Password to the key store.

Default Secure Setting:

· spark.ssl.keyStorePassword
<ssl-keystore-password>

Alternate Value or Change Command: None

Notes: None

File or command: spark-defaults.conf

Description: Path to the trust store file. The path can be absolute or relative to the directory in which the process is started.

Default Secure Setting:

· spark.ssl.trustStore /opt/mapr/conf/ssl_truststore

Alternate Value or Change Command: None

Notes: None

File or command: spark-defaults.conf

Description: Password for the trust store.

Default Secure Setting:

· spark.ssl.trustStorePassword
<ssl-truststore-password>

Alternate Value or Change Command: None

Notes: None

File or command: spark-defaults.conf

Description: The TLS protocol to use. The protocol must be supported by the JVM.

Default Secure Setting: · spark.ssl.protocol
TLSv1.2

Alternate Value or Change Command: None

Notes: None

File or command: spark-defaults.conf

Description: Configure encryption for the Spark HTTP file and broadcast servers

Default Secure Setting:

spark.ssl.enabledAlgorithms
TLS_RSA_WITH_AES_128_CBC_SHA, TLS_RSA_WITH_AES_256_CBC_SHA

Alternate Value or Change Command: None

Notes: None

Security Settings for Livy**File or command: livy.conf**

Description: MapR-SASL authentication

Default Secure Setting: livy.server.auth.type
= multiauth

File or command: /opt/mapr/elasticsearch/elasticsearch-5.4.1/usr/share/elasticsearch/plugins/search-guard-5/sgconfig/sg_internal_users.yml

Description: Kibana and Elasticsearch login account and password file

Default Secure Setting: admin:hash:
<\$2a\$12\$6ASxMQEBKYPyGUc10Ryle0hz3c8RrvPGb7oqLC9xGGwPxJFw0LJtq>

Alternate Value or Change Command: https://docs.datafabric.hpe.com/home/AdministratorGuide/Changing_Password_for_ES_Kibana.html

Notes: None

File or command: /opt/mapr/conf/ssl_truststore* and /opt/mapr/conf/ssl_keystore*

Description: SSL Keys

Default Secure Setting: Created at install, should rarely change, used by all web and REST HTTPS interfaces.

Alternate Value or Change Command: [Add site specific certificates with keytool utility](#)

Notes: None

Security Settings for Grafana

File or command: /opt/mapr/grafana/grafana-version/etc/grafana/grafana.ini

Description: Certificate File

Default Secure Setting: /opt/mapr/grafana/grafana-4.6.1/etc/grafana/cert.pem

Alternate Value or Change Command: None

Notes: None

File or command: /opt/mapr/grafana/grafana-version/etc/grafana/grafana.ini

Description: Certificate Key

Default Secure Setting: /opt/mapr/grafana/grafana-4.6.1/etc/grafana/key.pem

Alternate Value or Change Command: None

Notes: None

Security Exceptions

"Secure by default" means network-safe authentication and encryption. This page describes areas in which secure-by-default capabilities are not yet implemented for the Data Fabric platform or ecosystem components. Included where applicable, are links to more information to help you work around those issues.

Hive

MapR-SASL is not supported for Hive in HTTP mode.

Hue

Certificate verification is disabled on Hue.

NFSv3

NFSv3 is not secure by default, and there are no provisions for authentication or network encryption.

NFSv4

NOTE: NFSv4 refers to NFS version 4.1.

NFSv4 is not secure by default, but it can be secured using Kerberos to enable both encryption and authentication. See [Configuring NFSv4 Server for Kerberos](#) on page 1845.

OpenTSDB

There is no authentication or network encryption by default for read access over REST, and authentication and encryption cannot be enabled. However, note that no updates are allowed over REST; therefore, intruders cannot alter cluster metric data.

ZooKeeper

ZooKeeper supports server-to-server authentication by default, but ZooKeeper does not support encryption and cannot be configured to do so.

YARN

For Data Fabric 6.2.0 (EEP 7.0.0) and later, YARN is delivered as an ecosystem component. For more information, see [YARN](#) on page 5532.

Client Connections

The following sections describe how a client connects to local and remote Data Fabric clusters.

How Data Fabric Clients Connect to the Cluster

Explains how clients connect to a HPE Data Fabric cluster.

The Data Fabric client connects to the cluster via CLDB nodes. When a connection attempt fails, the Data Fabric client returns an error. When an existing connection is no longer available, the Data Fabric client attempts to reconnect to a CLDB node.

For information about installing the Data Fabric client, see [HPE Data Fabric Client](#) on page 360.

How the Data Fabric Client Establishes Connections to the Cluster

Client applications connect to a cluster via CLDB nodes. To identify the CLDB nodes, check the connection request or the `mapr-clusters.conf` file on the node that submits the connection request. When a client application attempts to connect to the cluster for the first time, the following scenarios can occur:

- At least one of the CLDB nodes is online, in which case the connection is successful.
- None of the CLDB nodes is online, in which case the connection attempt fails.
- The CLDB nodes are listed incorrectly (for example, the IP addresses are incorrect), in which case the connection attempt fails.

When a connection attempt fails, the Data Fabric client returns one of the following errors based on the application type:

Application Type	Error
C Application using HBase API	ErrorCode = 1.
C Applications using HDFS API	NULL handle
Java Application using HBase, OJAI, or file system API	java.io.IOException: Could not create FileClient
Java Application using Kafka API for HPE Data Fabric Streams	org.apache.kafka.common.errors.NetworkException.

How the Data Fabric Client Re-establishes Failed Connections to the Cluster

If the CLDB goes down after a client application establishes its first connection to HPE Data Fabric, the client behavior depends on the setting for the `fs.mapr.hardmount` property in the `core-site.xml` file. The `core-site.xml` file is located in the client installation directory.

- If `fs.mapr.hardmount` is set to `true`, the Data Fabric client is nonresponsive as it continuously attempts to reconnect to the CLDB. The Data Fabric client responds when the CLDB comes back online. This is the default behavior.

- If `fs.mapr.hardmount` is set to `false`, the Data Fabric client attempts to connect to each CLDB node that is listed in the `mapr-clusters.conf` file on the node that submitted the connection request. If all of the CLDB nodes are down, the Data Fabric client returns the error `EAGAIN/-EAGAIN` to the client application. This error indicates that a connection could not be established because the CLDB nodes were not available or because the request timed out for specific reasons. For example, heavy traffic might have caused the network to be slow, or other nodes were unavailable.

Configuring Timeout for Inactive Connections

Configure `fs.mapr.binding.inactive.threshold` in `core-site.xml`. This parameter accepts a value in seconds, and refreshes existing bindings before performing the next I/O, if the time from the previous I/O crosses the given threshold. For example:

```
<property>
<name>fs.mapr.binding.inactive.threshold</name>
<value>600</value>
</property>
```

In this example, when the client tries to send data to the CLDB after a certain idle time, the system checks if the specified time (here 600 seconds, which is 10 minutes) is crossed after the previous request was sent. If so, the system tears down the existing TCP connection and creates a new TCP connection for the file client and CLDB to use for communication.

How Clients Connect to the Replica

Provides an overview of what Replicas are, and how Data Fabric clients connect to them.

When a client connects to the Data Fabric cluster for I/Os, the client is directed to the replica with the shortest distance. To calculate the distance, every client is given a specific path based on whether the client is connecting from within the cluster or from outside the cluster.

For clients connecting from outside the cluster, because the topology is unknown, and Data Fabric defines the path based on the topology configured in the CLDB configuration property (`cldb.default.node.topology`), the default rack (which is hard-coded as `default-rack`), and the client IP address. For example, suppose the client IP address is `10.10.10.1` and the value for the CLDB configuration property is `default_topo`. The client topology (or path) is: `/default_topo/default_rack/10.10.10.1`.

For clients on the cluster, the client node has a known topology and the path is built based on that topology, rack, and the client IP address. For example, suppose the client IP address is `10.10.10.1` and the client node topology is `/topo1/rack1`, the client path is: `/topo1/rack1/10.10.10.1`.

Assume the following node topology:

For the client connecting from outside or within the cluster, the replica that the client connects to is calculated based on the client's node topology (or path) and the distance between the nodes on the cluster. When trying to find the nearest replica, the system does a distance calculation based upon how far away the replica is from the Data Fabric client looking for the replica and chooses the replica with the shortest topology or least number of hops from the client node. In the above example, the client connecting from:

- Outside the cluster with the path `/default_topo/default_rack/10.10.10.1` will connect to `replica2`
- Within the cluster with the path:
 - `/topo1/rack1/10.10.10.1` will connect to `replica1`

- /topo1/rack2/10.10.10.2 will connect to replica2
- /topo1/rack3/10.10.10.3 will connect to replica2

Locking Support in Data Fabric

Provides a synopsis of how Data Fabric supports locking for clients.

The Data Fabric file system does not support server-side locking. This means that locks are held by components outside of the filesystem layer and are therefore not shared or enforced globally. As a result, when locking is available, you will need to carefully understand exactly where this enforcement occurs and ensure that all programs using the same locks access them through the same enforcement point. Also, locks, when supported in Data Fabric, are always whole file locks and advisory, not mandatory. The following table describes the locking support in Data Fabric for the clients.

Client Type	Locking Support	Default Value	Notes
Hadoop	No	N/A	Hadoop does not support locking APIs.
FUSE-based POSIX	Yes	Lock	Data Fabric supports advisory locking using kernel locking. This lock is locally enforced on that single Linux host and not shared with other hosts. The lock is only meaningful if all users accessing the file are using FUSE and are on the same host.
Loopback NFS POSIX	No	N/A	No support in Data Fabric for locking. However, you can use Network Lock Manager to lock with the noLock option on the mount command. This lock is locally enforced on that single Linux host and not shared with other hosts. The lock is only meaningful if all lock users are using loopbacknfs and are on the same host.
NFS v3	No	N/A	No support for locking in Data Fabric. However, you can use Network Lock Manager to lock with the noLock option on the mount command. This lock is locally enforced on that single Linux host and not shared with other hosts. The lock is only meaningful if all lock users are using NFS v3 and are on the same host.

Client Type	Locking Support	Default Value	Notes
NFS v4	Yes	NoLock	Data Fabric supports advisory locking for NFS v4 server. The lock is enforced locally on the NFS v4 server, which means the lock is only meaningful if all lock users are using the same NFS v4 server. See Advisory Locking in NFS v4 on page 1854 for more information.

Understanding the HPE Data Fabric Data Access Gateway

The HPE Data Fabric Data Access Gateway is a service that acts as a proxy and gateway for translating requests between lightweight client applications and the HPE Data Fabric cluster.

For the EEP 5.0 release, the service is used by the HPE Data Fabric Database JSON REST API. Starting with the EEP 6.0 release, the service can be used by the Node.js, Python, C#, and Go OJAI clients. Beginning with the EEP 6.3.0 release, the service can be used by the Java OJAI thin client.

The OJAI clients that connect to the Data Access Gateway use [gRPC](#), an open-source RPC framework, to expose the HPE Data Fabric Database OJAI API to the client. RPC message headers for individual messages are encoded using [Protocol Buffers](#). The message payload is encoded using OJAI JSON encoding. Depending on whether your HPE Data Fabric cluster has security enabled, TLS is either enabled or disabled, by default, for the gRPC service. When TLS is enabled, the SSL provider is OpenSSL.

The service runs on nodes in your HPE Data Fabric cluster. You can install the service [manually](#) or by using the [Installer](#) on page 7511. Both installation methods support upgrades of existing HPE Data Fabric

clusters. When installing the service, you can decide the number of nodes on which to install the service. The number of nodes you need depends on your scalability requirements.

Regardless of your scalability requirements, you should install the service on at least two nodes to provide high availability. To load balance requests and to achieve high availability and failover, you must use an external load balancer. For recommendations and best practices when using an external load balancer with gRPC, see [gRPC Load Balancing](#).

The service runs as user `mapr`. However, the service issues all data access calls on behalf of the user requesting the data. For example, if user `john` is running the client application, the service reads data using the authorization of `john`, not `mapr`.

All traffic between the Data Access Gateway and other HPE Data Fabric services is encrypted. This is done regardless of whether the underlying HPE Data Fabric file system volume has encryption enabled.

[Warden](#) on page 886 manages the HPE Data Fabric Data Access Gateway. It handles stopping and starting of the service during node failovers and also controls the amount of memory assigned to the service.

Related concepts

[Using the HPE Data Fabric Database JSON REST API](#) on page 3887

Starting in the EEP 5.0 release, you can use a REST API to access HPE Data Fabric Database JSON tables. The REST API allows you to use HTTP calls to perform basic operations on HPE Data Fabric Database JSON tables.

[Using the Node.js OJAI Client](#) on page 3862

Starting with EEP 6.0, you can use the Node.js OJAI client to write HPE Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Data Fabric Database JSON from middleware components, and add, update, and query documents in a HPE Data Fabric Database JSON table.

[Using the Python OJAI Client](#) on page 3867

Starting with EEP 6.0, you can use the Python OJAI client to write HPE Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Data Fabric Database JSON, and add, update, and query documents in a HPE Data Fabric Database JSON table.

[Using the C# OJAI Client](#) on page 3877

Starting with EEP 6.1.0, you can use the C# OJAI client to write HPE Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Data Fabric Database JSON, and add, update, and query documents in a HPE Data Fabric Database JSON table.

[Using the Go OJAI Client](#) on page 3881

Starting with EEP 6.0.0, you can use the Go OJAI client to write HPE Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Data Fabric Database JSON, and add, update, and query documents in a HPE Data Fabric Database JSON table.

[Using the Java OJAI Thin Client](#) on page 3859

Starting with EEP 6.3.0, you can use the Java OJAI Thin Client to write HPE Data Fabric Database JSON applications. The Java OJAI Thin Client provides a lightweight library that supports the OJAI API. You can connect to HPE Data Fabric Database JSON, and add, update, and query documents in a HPE Data Fabric Database JSON table.

[Administering the Data Access Gateway](#) on page 2235

The HPE Data Fabric Data Access Gateway is a service that acts as a proxy and gateway for translating requests between lightweight client applications and the HPE Data Fabric cluster. This section describes considerations when upgrading the service, how to modify configuration settings, and how to administer and manage the service.

Related tasks

[Installing Data Access Gateway](#) on page 316

This topic includes instructions for using package managers to download and install the Data Access Gateway from the EEP repository.

8.1.0 Administration

This section describes how to manage the nodes and services that make up a cluster.

This section is for system administrators tasked with managing Data Fabric clusters. Topics include how to manage data by using volumes, how to monitor the cluster for performance, how to manage users and groups, how to add and remove nodes from the cluster, and more. The focus of this section is managing the nodes and services that make up a cluster using the Control System and the CLI or REST API.

Working with Multiple Fabrics Using the Data Fabric UI

This section describes how you can get started learning about, installing, and using the HPE Data Fabric.

The [Data Fabric UI](#) on page 1100 serves as a data plane for all your data sources ranging from fabrics created on Data Fabric, S3-compliant object stores in the cloud, and third-party NFS servers.

You can use the Data Fabric UI to work with more than one fabric at a time, including on-premise fabrics and fabrics created on public cloud providers such as AWS, GCP, and Microsoft Azure. You can import external data sources such as third-party NFS servers and S3-compliant object stores into your global namespace to get a unified view of all your data sources on the Data Fabric UI.

The Data Fabric UI can be installed by using the procedure given in [Installing with a Seed Node](#) on page 99.

For upgrading to the latest release version, see [Upgrading a Seed Node Fabric](#) on page 447.

If you plan to deploy a fabric on a public cloud provider such as Amazon Cloud Services, Microsoft Azure, or Google Cloud Platform, you must first read about the [Considerations for Data Fabric Deployment on Cloud](#) on page 1107.

Before you start working with multiple fabrics in your hybrid cloud environment or on-premise, familiarize yourself with [Data Fabric Terminology for Working with Multiple Fabrics](#) on page 1100.

Data Fabric Terminology for Working with Multiple Fabrics

The important terminology related to working with multiple fabrics by using the Data Fabric UI is listed below.

NOTE: The term 'fabric', when used with the Data Fabric UI or elsewhere in the Data Fabric documentation, is an alternate form of the term 'cluster' from the Control System and the command line. Both terms are used interchangeably in the Data Fabric documentation.

Other terminology related to Data Fabric remains unchanged. See the [glossary](#) to understand the other terms used in the Data Fabric documentation.

Data Fabric UI

Describes the graphical user interface for the HPE Data Fabric.

About the Data Fabric UI

The Data Fabric UI is the browser-based, graphical user interface that you use to monitor and manage the HPE Data Fabric.

 **NOTE:** NFSv4 refers to NFS version 4.1.

The Data Fabric UI facilitates the management of all your data sources. Your data sources could comprise one or more fabrics that have been created using HPE Data Fabric, external data sources that belong to your organization. External data sources could be cloud-based external S3 servers and/or NFSv4 servers that have been imported into HPE Data Fabric and comprise the [global namespace](#).

The following image displays the tabular view of resources on the All Resources page of the Data Fabric UI.

Some of the operations that you can perform by using the Data Fabric UI are as follows:

- Create or import fabrics
- Create volumes
- Create volume mirrors and snapshots
- Create buckets
- Create topics
- Manage users
- Control access to data with storage policies and security policies
- Monitor system resources

The following image lists the icons on the Data Fabric UI and the corresponding pages that appear on clicking the available icons.

Click the icon to access the Home page

Click the icon to access the All resources page

Click the icon to access the Monitoring page

Click the icon to access the Fabric administration page

Click the icon to access the Security administration page

The Data Fabric UI

comprises the following pages:

- The **Home** page presents a summary of system resources, capacity utilization, and alarms that are generated by the HPE Data Fabric events and user actions.
- The **All resources** page facilitates the management of the global namespace, and the resources in the global namespace.
- The **Monitoring** page presents a summary of system resources, fabric storage utilization to monitor.
- The **Fabric administration** page facilitates the fabric administration operations that include configuring user quota, managing fabric access, creating remote targets, adding endpoints, managing storage policy.
- The **Security administration** menu facilitates identity policy management, security policy management, and SSO configuration.

Launching the Data Fabric UI

To launch the Data Fabric UI, navigate to the host that is running the WebServer in the fabric. Access to the fabric typically uses HTTPS on port 8443. For example:

```
https://<host-name>:8443/app/dfui
```

Global Namespace (GNS)

Describes the data plane that connects all of your HPE Data Fabric deployments.

Because enterprise data is scattered across multiple sources between edge, core, and multi-cloud, a mechanism is needed to enable access to the data seamlessly, irrespective of the data location. The global namespace is a solution that aggregates disparate and remote data sources and provides a namespace that encompasses all of your infrastructure and deployments. The global namespace maintains the native security model of the HPE Data Fabric, so that location details are abstracted from the application.

Global namespace technology lets you manage globally deployed data as a single resource. Because of the global namespace, you can view and run multiple fabrics as a single, logical, and local fabric. The global namespace is designed to span multiple edge nodes, on-prem data centers, and clouds:

NOTE: NFSv4 refers to NFS version 4.1.

A global namespace stitches multiple data sources into a single accessible entity and provides multiple data access points, where each access point shows the same hierarchical namespace. The entire group of data sources could be accessed and operated by using any one of the access points, without any need to know the source's physical data location.

In the global namespace, all fabrics can view all other fabrics. The Data Fabric UI shows the global namespace on the **All resources** page in the **Graph view**.

Following is a sample screenshot for the graph view.

The global namespace is available in the Table view. If you have an elaborate list of fabrics and fabric resources in your global namespace, it might be a good idea to view the resources in the table view. To view resources in the table view, you must click the table view icon that is placed to the right of the **Actions** menu.

Following is a sample screenshot for the table view.

The Data Fabric also supports adding external NFSv4 and external S3 object stores to a global namespace.

In support of S3 object stores, S3 clients can access multiple fabrics by using a single endpoint after specifying a single pair of access key and secret key.

S3 Federation in Global Namespace

Provides an overview of S3 federation in the global namespace

Data Fabric provides a native implementation of the S3 object store for object management. You can access data from multiple fabrics with the native S3 object store implementation.

Additionally, Data Fabric provides a mechanism to access data that is stored on S3-compliant object stores from vendors other than HPE, such as Amazon Web Services (AWS), Google Cloud Platform (GCP), Scality, WEKA, VAST, to name a few.

A third-party object store that is managed by vendors other than HPE is referred to as an external S3 object store (external S3 server).

See [Third-Party Storage Solutions](#) on page 7765 for details about the third-party storage solution compatibility with HPE Data Fabric.

S3 federation is a federation of one or more Data Fabric native S3 servers and/or one or more external S3 servers in the global namespace.

You can access remote S3 servers imported into your global namespace from any fabric in the same global namespace, by obtaining the access points to the object stores.

All buckets and objects from your native and external S3 servers can be accessed on the global namespace via the Data Fabric UI.

Data Fabric acts as the intermediary between a S3 client and an external S3 server that is imported into the global namespace. Data Fabric forwards requests coming from S3 clients to the external S3 server. The responses from the external S3 server are transported back to the requesting S3 clients via Data Fabric.

By default, Data Fabric works in forwarding mode with external S3 servers in their communication with S3 clients via Data Fabric. Data Fabric forwards the S3 client request to the external S3 server by using the secret key-access key pair that has been used to import the S3 server into the global namespace. The forwarding mechanism that happens during the S3 client-external S3 server communication consumes CPU and memory resources on Data Fabric. This can impact the Data Fabric performance, depending on the use case for frequency of communication between the S3 client and external S3 server.

NOTE: Currently, there is no performance benchmark available on Data Fabric performance for S3 client-external S3 server communication.

Data Fabric can work in redirection mode for S3 client-native S3 server communication with the [cluster group s3gns command](#). Data Fabric redirects an incoming S3 client request made to a native S3 server on another fabric in the same global namespace. Once the redirection is successful, the communication between the S3 client and the native S3 server on the other fabric takes place directly. In case of redirection, there is no impact on Data Fabric performance.

Prerequisites for S3 Federation

Following are the prerequisites for S3 federation on a global namespace.

- External S3 servers and fabrics in the global namespace must be able to communicate with one another over the network.
- An external S3 server and an individual fabric in the global namespace must have a pair of secret key and access key that is authorized on the external S3 server, and can be used by the fabric to forward S3 client request to the external S3 server.

See [Working with an External S3 Object Store](#) on page 1259 for details on managing external S3 servers via the Data Fabric UI.

S3 Global Namespace

Describes what is meant by S3 global namespace.

Introduction

S3 global namespace is a subset of the [global namespace](#) that comprises the native S3 storage (S3 storage on fabrics) and external S3 storage that are part of the global namespace.

A S3 client can authenticate all the S3 storage across fabrics in the S3 global namespace, by using a single set of access key/secret key.

A S3 client uses keys to connect to a S3 server. When the S3 GNS is explicitly enabled, the S3 client can choose any S3 server out of all the available native s3 servers to connect, and the same pair of keys should be valid on all of the native S3 servers. This is achieved by way of replicating the required tables across connected native fabrics. Enabling of s3 global namespace can be done from the command line.

The S3 global namespace also provides a unified control plane for all native S3 storage (S3 storage on fabrics) accessed from the Data Fabric UI.

For the incoming s3 client requests intended for a remote/external s3 server, there are two ways the request can be handled:

- by redirecting the request to the correct s3 server
- by returning http forward error and letting the client to connect to the target s3 server directly.

Data Fabric works in redirection mode for S3 client - native/fabric S3 storage communication. Data Fabric redirects an incoming S3 client request made to a native S3 server on another fabric in the same global namespace. Once the redirection is successful, the communication between the S3 client and the native S3 server on the other fabric takes place directly.

Data Fabric works in forwarding mode for S3 client - external S3 storage communication.

NOTE: Data Fabric serves only as a unified data plane for external S3 servers that are imported into the global namespace. The control plane for the external S3 servers is accessible by using the respective interface or utility provided by the individual external S3 server. For example, bucket management can be performed on AWS S3 by using the AWS Management Console or AWS CLI.

Enable S3 global namespace

By default, S3 global namespace is disabled on a global namespace.

When you enable S3 global namespace, the access keys, secret key and IAM policies from the primary fabric are replicated across all fabric storage or native S3 storage. The keys and IAM policies that exist on the non-primary fabrics in the S3 global namespace are overwritten on enabling S3 global namespace.

CAUTION: Enabling of S3 global namespace is a disruptive operation and must be performed only when it is feasible to have a single set of keys and policies across all the native S3 object stores/servers in your global namespace.

Use the `clustergroup s3gns enables3gns` command to enable S3 global namespace on the S3 storage across fabrics in your global namespace.

ATTENTION: In the global namespace, there is no cross-protocol support across fabrics. Within a fabric, Data Fabric supports accessing files as objects. This functionality is not supported across fabrics.

For instance, if you have two fabrics, both containing files and objects, in the global namespace:

- You can use the `mc` command to access objects from any bucket across fabrics in the global namespace.

NOTE: NFSv4 refers to NFS version 4.1.

You can use NFSv4 to access files of any volume across fabrics in the global namespace.

You cannot use `mc` or an `s3` client to access files from any volume on other fabrics in the global namespace.

Network File System in Global Namespace

Describes the federation of network file system in the global namespace.

A network file server(NFS) is hosted on a remote network, typically in a different physical location. The remote network file servers provide file-sharing services using NFS, allowing clients from different networks or locations to access and share files over the network.

NOTE: NFSv4 refers to NFS version 4.1.

HPE Data Fabric offers a native implementation of NFSv4. Data stored in the native NFSv4 system can be accessed from the global namespace.

The global namespace can be extended by importing one or more NFSv4 systems offered by vendors other than HPE. The NFSv4 system that is offered by vendors other than HPE is referred to as an external NFS with respect to Data Fabric.

An external NFS that is imported into Data Fabric appears as a part of the global namespace on the Data Fabric UI.

Data Fabric aggregates native NFSv4 systems and/or external NFSv4 systems in the global namespace, such that data from all the relevant NFSv4 systems in the global namespace is accessible via Data Fabric.

The addition of an external NFS to the global namespace facilitates the federation of all your NFS data, irrespective of the NFS vendor and the location of the data.

Data Fabric refers requests coming from an NFSv4 client to an external NFSv4 server that has been imported into Data Fabric. Once the connection between the NFSv4 client and the external NFSv4 server is established, the communication and data exchange between the NFSv4 client and external NFSv4 server takes place directly. Data Fabric is not a part of this communication.

See [Working with an External NFS Server](#) on page 1257 for details on importing an external file system into the global namespace via the Data Fabric UI.

See [Third-Party Storage Solutions](#) on page 7765 for details about the third-party storage solution compatibility with HPE Data Fabric.

Considerations for Data Fabric Deployment on Cloud

Describes the considerations for deployment of Data Fabric on public cloud providers such as Amazon Web Services, Google Cloud Platform and Microsoft Azure.

Data Fabric supports fabric creation on the following public cloud service providers:

- Amazon Web Services
- Google Cloud Platform
- Microsoft Azure

Before you can create and work with a fabric on any of the supported cloud providers, you must go through the requirements or pre-requisites for the respective cloud provider.

See the individual topics listed below to understand the architecture considerations to deploy Data Fabric on the respective public cloud provider.

Cloud Instance Specifications

Compares different aspects of the supported cloud instances of the HPE Data Fabric.

AWS Cloud Instance Specifications

The following table describes the AWS cloud instance for different storage tiers:

Specification	Storage Tier				
	100GB	1TB	10TB	100TB	1PB
Number of Instances	1	3	5	10	15
Instance Type	m6i.4xlarge	m6i.4xlarge	m6i.4xlarge	m6i.4xlarge	m6i.4xlarge
Number of DF Disks	1	3	4	10	14
DF Disk Type	st1	gp3	gp3	gp3	gp3
DF Disk Size	128	128	512	1024	5120
Swap Disk Type	gp3	gp3	gp3	gp3	gp3
RAM	64GB	64GB	64GB	64GB	64GB
CPU	16	16	16	16	16
Swap Disk Size	16	64	128	256	512

Azure Cloud Instance Specifications

The following table describes the Azure cloud instance for different storage tiers:

Specification	Storage Tier				
	100GB	1TB	10TB	100TB	1PB
Number of Instances	1	3	5	10	15
Instance Type	Standard_B 12ms	Standard_B 16ms	Standard_B 16ms	Standard_B 20ms	Standard_B 20ms
Number of DF Disks	1	3	4	10	14

Specification	Storage Tier

AWS Architecture Notes

Describes architectural considerations for the HPE Data Fabric platform when deployed on Amazon AWS.

Deployment Topology

To take advantage of the benefits of cloud computing, you can provision a fabric in Amazon AWS and in other public clouds. A single instance of the Data Fabric is referred to as a [Fabric](#). The fabric provides a high-performance file system for files, objects, tables, and streaming files and can be deployed quickly and easily. The HPE Data Fabric is designed so that many fabrics deployed in different public clouds or on premises can communicate with each other seamlessly in a [global namespace \(GNS\)](#).

The following diagram shows the high-level architecture for a single cloud-based fabric on AWS:

Deployment Prerequisites

At a minimum, the user who deploys the Data Fabric on AWS must have [AmazonEBSCSIDriverPolicy](#) and [AmazonEC2FullAccess](#) permissions and must provide information such as the:

- Fabric name
- Access key
- Secret key
- Region
- Virtual private cloud (VPC) ID
- Public subnet ID

For more information, see .

Public and Private Subnets

To enable a global namespace consisting of many fabrics accessible over the internet, the user must provide a public subnet. The global namespace cannot currently be implemented with private subnets. The Data Fabric architecture does not prevent the use of private subnets, but some code changes are required before private subnets can be supported. Note that air-gapped, on-premises installations are fully supported.

Regions and Availability Zones

The Data Fabric can be deployed into the following AWS regions:

- US East (Ohio)

- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Asia Pacific (Mumbai)
- Asia Pacific (Hyderabad)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Melbourne)

In the current architecture, all fabric instances reside in a specific subnet, which is contained within a single availability zone (the default availability zone).

Amazon Machine Images (AMIs)

Users of the HPE Data Fabric do not need to create or manage the AMIs needed to support the Data Fabric on AWS. HPE provides a set of publicly available AMIs that facilitate installation and upgrade of the fabric without the need for user interaction.

Security Groups

During fabric creation, a security group is created for each fabric. The security group is configured with predefined in-bound and out-bound rules to support the list of [ports](#) required for fabric-to-fabric communication.

STS Support for AWS S3 Object Stores

With release 7.7.0 and later, Data Fabric provides a new option for gaining access to AWS S3 object stores. You can import an external AWS S3 server by using the `mapcli clustergroup addexternal` command and specifying an Amazon Resource Name (ARN) to enable STS authentication. For more information, see [Integrating the AWS Security Token Service \(STS\) with Data Fabric](#) on page 1265.

Using STS simplifies the process of accessing AWS services by using STS tokens for authentication. With STS tokens, the Data Fabric user can assume an AWS role and get temporary credentials to perform S3 actions. Once the external S3 object store is imported into the global namespace, **all S3 operations** automatically use STS.

Instance, Disk, and Memory Information

See [AWS Cloud Instance Specifications](#) on page 1107.

Upgrades

When a new software version is available, the user is notified. At the user's discretion, the platform can perform a non-disruptive, rolling upgrade from one major software version to another. However, upgrade capability is currently limited to on-premises deployments. See

Scaling

Adding nodes to a fabric can be done using a rolling upgrade process. Note that adding nodes is currently supported only for on-premises deployments. See [Adding a Node to On-premise Fabric](#) on page 1127.

Administrative Interface

The [Data Fabric UI](#) on page 1100 provides a browser-based graphical user interface for monitoring and managing all fabrics in a global namespace.

SSO and Predefined Roles

The Data Fabric leverages the Keycloak identity and access management (IAM) solution to ensure that all the fabrics in a global namespace have access to the same user information. Keycloak can be used as a passthrough with other popular IAM solutions.

SSO-configured fabrics support the following predefined roles when you install Keycloak while installing the fabric:

- Infrastructure Admin
- Fabric Manager
- Fabric User

For more information about the permissions granted to each role, see [Pre-defined Roles and Associated Permissions](#) on page 1154.

Azure Architecture Notes

Describes architectural considerations for the HPE Data Fabric software-as-a-service (SaaS) platform when deployed on Microsoft Azure.

Deployment Topology

To take advantage of the benefits of cloud computing, you can provision a fabric in Microsoft Azure and in other public clouds. A single instance of the Data Fabric is referred to as a [Fabric](#). The fabric provides a high-performance file system for files, objects, tables, and streaming files and can be deployed quickly and easily. The HPE Data Fabric is designed so that many fabrics deployed in different public clouds or on premises can communicate with each other seamlessly in a [global namespace \(GNS\)](#).

The following diagram shows the high-level architecture for a single cloud-based fabric on Azure:

Deployment Prerequisites

At a minimum, the user who deploys the Data Fabric on Azure must have the [Contributor role](#) and must provide information such as the:

- Azure tenant ID
- Subscription ID
- Client ID
- Client secret
- Region
- Resource group name
- Virtual network
- Subnetwork

For more information, see .

Public and Private Subnets

To enable a global namespace consisting of many fabrics accessible over the internet, the user must provide a public subnet. The global namespace cannot currently be implemented with private subnets. The Data Fabric architecture does not prevent the use of private subnets, but some code changes are required before private subnets can be supported. Note that air-gapped, on-premises installations are fully supported.

Regions and Availability Zones

The Data Fabric can be deployed into the following Azure regions:

- East US
- East US 2
- West US
- West US 2

In the current architecture, all fabric instances reside in a specific subnet, which is contained within a single availability zone (the default availability zone).

Network Security Groups

During fabric creation, a network security group is created for each fabric. The network security group is configured with predefined in-bound and out-bound rules to support the list of [ports](#) required for fabric-to-fabric communication.

Instance, Disk, and Memory Information

See [Azure Cloud Instance Specifications](#) on page 1107.

Upgrades

When a new software version is available, the user is notified. At the user's discretion, the platform can perform a non-disruptive, rolling upgrade from one major software version to another. However, upgrade capability is currently limited to on-premises deployments. See .

Scaling

Adding nodes to a fabric can be done using a rolling upgrade process. Note that adding nodes is currently supported only for on-premises deployments. See [Adding a Node to On-premise Fabric](#) on page 1127.

Administrative Interface

The [Data Fabric UI](#) on page 1100 provides a browser-based graphical user interface for monitoring and managing all fabrics in a global namespace.

SSO and Predefined Roles

The Data Fabric leverages the Keycloak identity and access management (IAM) solution to ensure that all the fabrics in a global namespace have access to the same user information. Keycloak can be used as a passthrough with other popular IAM solutions.

SSO-configured fabrics support the following predefined roles:

- Infrastructure Admin
- Fabric Manager
- Fabric User

For more information about the permissions granted to each role, see [Pre-defined Roles and Associated Permissions](#) on page 1154.

GCP Architecture Notes

Describes considerations related to Google Cloud Platform(GCP) for the HPE Data Fabric software platform for deployment to GCP.

Deployment Overview

You can provision a fabric in Google Cloud Platform (GCP) and in other public clouds to take advantage of the benefits of cloud computing. A single instance of Data Fabric is referred to as a [Fabric](#). The fabric provides a high-performance file system for files, objects, tables, and streaming files and can be deployed quickly and easily. The fabric makes use of the storage provided by the Google Cloud Platform to store the fabric data.

GCP Credentials

You would require the following GCP cloud credentials to access GCP for fabric creation on GCP.

- service account key file

GCP Services

The following table details the GCP services that are relevant to provisioning Data Fabric on GCP.

GCP Service	Description/Purpose
VPC	High-level GCP service for cloud-based fabric deployment
Google cloud image (AMI equivalent)- OS image	Required to create an operating system image on GCP
Google compute instance/ VM instance- custom image (base OS images+DF packages)	Required to host base operating system image instances plus Data Fabric packages. Can be used to generate a VM instance from the custom image on which Data Fabric would be installed.
Google compute disk	Required for storage of fabric data.
Subnet	Required for network communication between GCP and Data Fabric. You must create the required number of public subnets. Private subnet is not supported for Data Fabric. You must configure firewall rules to manage subnet access for Data Fabric. For information on required ports on which various Data Fabric components communicate, see port information

Permissions required to access GCP resources

GCP implements IAM roles for the purpose of managing access to GCP cloud resources.

In general, you must be assigned one of the following roles to be able to provision and manage fabrics on GCP.

- Compute Instance Admin(v1)
- Compute Security Admin

Regions and Zones

A fabric can be provisioned on any the GCP zones that are available to you while creating the fabric via the Data Fabric UI.

Following are the GCP zones on which you should be able to create a fabric.

- Council Bluffs, Iowa, North America -us-central1-a
- Council Bluffs, Iowa, North America -us-central1-b
- Council Bluffs, Iowa, North America -us-central1-c
- Council Bluffs, Iowa, North America -us-central1-f
- Moncks Corner, South Carolina, North America -us-east1-b

- Moncks Corner, South Carolina, North America -us-east1-c
- Moncks Corner, South Carolina, North America -us-east1-d
- Ashburn, Virginia, North America -us-east4-a
- Ashburn, Virginia, North America -us-east4-b
- Ashburn, Virginia, North America -us-east4-c
- Columbus, Ohio, North America -us-east5-a
- Columbus, Ohio, North America -us-east5-b
- Columbus, Ohio, North America -us-east5-c
- Dallas, Texas, North America -us-south1-a
- Dallas, Texas, North America -us-south1-b
- Dallas, Texas, North America -us-south1-c
- The Dalles, Oregon, North America -us-west1-a
- The Dalles, Oregon, North America -us-west1-b
- The Dalles, Oregon, North America -us-west1-c
- Los Angeles, California, North America -us-west2-a
- Los Angeles, California, North America -us-west2-b
- Los Angeles, California, North America -us-west2-c
- Salt Lake City, Utah, North America -us-west3-a
- Salt Lake City, Utah, North America -us-west3-b
- Salt Lake City, Utah, North America -us-west3-c
- Las Vegas, Nevada, North America -us-west4-a
- Las Vegas, Nevada, North America -us-west4-b
- Las Vegas, Nevada, North America -us-west4-c

Instance, Disk, and Memory Information

See [GCP Cloud Instance Specifications](#) on page 1108.

Upgrades

When a new software version is available, the user is notified. At the user's discretion, the platform can perform a non-disruptive, rolling upgrade from one major software version to another. See .

Working with the Data Fabric UI

Describes how to work with the Data Fabric UI to manage multiple fabrics on-premise or in a hybrid cloud environment.

The Data Fabric UI that is installed with the seed node installer. For the Data Fabric UI installation procedure, see [Installing with a Seed Node](#) on page 99.

It is important to understand each of the terminologies before you begin working with the Data Fabric UI. See [Data Fabric Terminology for Working with Multiple Fabrics](#) on page 1100

to understand the key Data Fabric UI terminology.

Administering Fabrics

This section describes fabric operations that you can perform using the Data Fabric UI.

A data fabric is a collection of nodes that work together under a unified architecture, along with the services or technologies running on that architecture. Fabrics help you manage your data, making it possible to access, integrate, model, analyze, and provision your data seamlessly.

Using the [Data Fabric UI](#) on page 1100, you can create fabrics hosted by the following providers:

- AWS
- Azure
- GCP
- On-premises

Configuring a Proxy Server for Data Fabric Access to the Internet

Describes the procedure to configure an https or http proxy for scenarios where communication between the internet and Data Fabric must happen over a proxy server.

Prerequisites

You must be a fabric manager to be able to perform this task.

About this task

Depending on the network configuration, Data Fabric might require to connect to the internet via a proxy server for download of Data Fabric packages, or to communicate with the SSO server that might be outside of the network in which Data Fabric is installed. A https or http proxy server can serve as a common routing point for internet access from Data Fabric.

It is recommended to use an https proxy for secure communication between Data Fabric and any server to be accessed over the internet.

You may, optionally, specify a http proxy server for any communication over http.

The format to specify the proxy server is <proxy-server-url>:<portnumber>.

Some Data Fabric components are auto-restarted when you save the proxy settings. You are required to refresh the Data Fabric UI after about 15 to 20 minutes after saving the proxy settings.

NOTE: If you have signed in to the Data Fabric UI by using your single sign-on (SSO) credentials, your session is active, and it should suffice to refresh the page in the web browser after the restart of Data Fabric components. If you are a non-SSO user, you must log off and log back in to the Data Fabric UI.

Follow the steps given below to configure a proxy server.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Fabric administration icon on the left pane.

3. On the **Select fabric** dropdown, select the fabric for which you wish to configure the proxy settings.
4. Click the **Settings** tab.
5. On the **Fabric Settings** card, click the Edit icon adjacent to **Proxy configuration**.
6. Enter the https proxy URL and port number in **HTTPS proxy** in the <proxy-server-url>:<portnumber> format.
7. Optionally, enter the http proxy URL and port number in **HTTP proxy** in the <proxy-server-url>:<portnumber> format.
8. Click **Save**.

Results

The proxy settings are saved. Some Data Fabric components restart and this might result in an error after about 15 minutes of saving the proxy settings. Refresh the Data Fabric UI page that you are working on at such time.

Creating a Fabric

Fabrics make it possible for you to create volumes, buckets, and topics in a cloud or on-premises deployment. If your organization has multiple departments or multiple use cases to support, you can create multiple fabrics.

This page describes the basic steps to create a new *Fabric* for any of the supported fabric providers (AWS, Azure, GCP, and on-premises).

Before Creating a Fabric

Note these considerations:

- If you are creating your first fabric, see [Installing with a Seed Node](#) on page 99. You must use the seed node steps to create your first fabric. For all subsequent fabrics you can use the steps on this page.
- To create a fabric, you must have fabric manager [credentials](#). The **Create Fabric** button is not displayed for developer and infrastructure admin credentials.
- Always create fabrics one at a time. You cannot create multiple fabrics at the same time.
- Creating an on-premises fabric requires that you provide host nodes *before* starting fabric creation. These nodes must meet certain requirements. Before creating an on-premises fabric, review [Prerequisites for On-Premises Installation](#) on page 112.
- You can choose to install keycloak along with HPE Data Fabric. If you are to use an external Keycloak server, keep the Keycloak server details handy.

Steps for Creating a Fabric

Use the following steps to create a new fabric.

1. Log on to the Data Fabric UI with Fabric Manager credentials.
2. Click the All resources icon on the left pane.
3. Select the **Create fabric** option from the **Actions** dropdown.

Progress bar steps: Fabric details, Provider, Identity provider, Services, Database Configuration, Review.

Name*

thefirstfabric

Provider

On-premises

See [On-Premises Fabric Configuration Parameters](#) for details about each field.

Airgap repository

The repository must contain nested folders `"/installer/redhat"`.

Enter airgap repository

4. Enter the **Name**.
5. Select the cloud provider on which you want to create. Alternatively, you could select on-premise to create an on-premise fabric.
6. Encryption for data at rest is enabled by default. Do not to turn off the setting unless required.
7. If you wish to opt out of auto-installation of the latest available patch for your Data Fabric version on the fabric, turn off the **Apply latest patch** toggle. The toggle is on, by default, indicating that the latest patch for your Data Fabric version is auto-installed on the fabric, whenever HPE makes it available to you. This is an optional step.
8. Under **Administrator Details**, enter the **Admin user password** for the mapr user. mapr is the default admin user.
9. Click **Next**.

The screenshot displays a configuration wizard for HPE Data Fabric. At the top, a progress bar shows six steps: 'Fabric details', 'Provider' (the current step, highlighted with a green dot), 'Identity provider', 'Services', 'Database Configuration', and 'Review'. Below the progress bar, the 'Provider' section contains a dropdown menu with 'On-premises' selected. The 'SSH credentials' section includes a 'Username*' field with 'root' and a 'Password*' field with masked characters and a toggle icon. The 'Fabric details' section shows a 'Nodes*' label and a 'Node FQDN' input field.

10. Fill in the configuration parameters for the type of fabric you want to create:

- [AWS Fabric Configuration Parameters](#) on page 115
- [Azure Fabric Configuration Parameters](#) on page 117
- [GCP Fabric Configuration Parameters](#) on page 119
- [On-Premises Fabric Configuration Parameters](#) on page 120

11. Click **Next**.

Create your first fabric

12. On the **Identity Provider** page, select the appropriate option. Select the **Install keycloak** option, if you wish to install keycloak that comes with HPE Data Fabric. To interface with an existing external Keycloak server, select the **Configure keycloak** option. See [Configuring Keycloak as Identity Provider for SSO](#) on page 1125 for details. If you do not wish to install keycloak, select the **Do not install** option.

13. If you wish to install EEP components, click the down arrow for **Advanced Settings** to view the available auto-provisioning EEP templates. Select the auto-provisioning template of your choice. This is an optional step.

See [DEP Component Installation during Fabric Creation](#) on page 150 for details about the list of auto-provisioning templates for EEP.

14. Click **Next**.

The screenshot shows a progress bar at the top with six steps: Fabric details, Provider, Identity provider, Services, Database Configuration (highlighted), and Review. Below the progress bar, the 'Database setup' section is visible. It includes a heading 'Database setup' and a subtext 'Select embedded database, existing MySQL server, or installer handles it.' Under the 'Hive Metastore' section, there is a 'Database type*' dropdown menu with the option 'Use embedded database (may limit functionality)' selected. Below this, the 'Hue' section is partially visible, also showing a 'Database type*' dropdown.

15. If you have selected an auto-provisioning EEP template where database configuration is applicable, select the appropriate option.

16. Click **Next**.

Fabric details

Basic details

Name thefirstfabric	Provider OnPrem	Airgap repository --
Data at rest encryption Yes	IPv6 support No	Apply latest patch Yes

Administrator Details

Admin user name mapr	Admin user password *****
--------------------------------	-------------------------------------

17. Review the fabric configuration.
18. Click the pencil icon to edit any section of the configuration, if required.
19. Click **Submit**.
20. To monitor the progress of fabric creation, check the status bar in the **Fabric details** dialog box, or click **See details**. Fabric creation can take 20 minutes or more.
 If fabric creation fails, you can retry the operation. Click the ellipsis in the **Action** column, and select **Reinitiate**.
 It is possible for fabric creation to fail because of a host-name resolution issue. See [Troubleshooting Seed Node Installation](#) on page 122.
 If fabric creation continues to fail, and the failure cannot be resolved manually, contact [HPE Support](#).
21. When the installation status shows **Installed**, click the ellipsis () in the **Action** column, and select **View endpoints**. The URL for the new fabric is displayed, and you can copy the URL to the clipboard.

Importing a Fabric

Describes the steps to import a fabric into the global namespace.

Considerations for Importing a Fabric

When you are logged in to a fabric by using the <keyword conkeyref="mapr_vars/PN_dfui">, you can import another fabric into the global namespace.

A fabric can belong to only one global namespace at a time. Thus, the act of importing a fabric necessarily removes the fabric from the global namespace to which it currently belongs.

To view the current list of fabrics in your global namespace, display the **Table view** or **Graph view** on the **All Resources** page of the Data Fabric UI.

Note these considerations:

- Only fabrics configured for SSO can be imported.
- To import a fabric, you must be an SSO user and have Fabric Manager or Fabric User [credentials](#).
- You can only import one fabric at a time.
- You must have a consumption license for each new fabric that you import.

Preparing to Import a Fabric

1. On the fabric that you plan to import, stop Keycloak:

- a. Use the following command to identify the host running the mapr-keycloak service:

```
maprcli node list -columns svc
```

In the command output, look for a host that shows keycloak in the service column. If no host shows the mapr-keycloak service in the service column, go to step 2.

- b. Stop the mapr-keycloak service:

```
maprcli node services -name keycloak -action stop -nodes -json
```

2. On the fabric that you plan to import, reset the SSO information:

- a. Reset the SSO configuration:

```
maprcli cluster resetssoconf -json
```

- b. Restart the mapr-apiserver services on the fabric hosts:

```
maprcli node services -name apiserver -action restart -nodes  
host1,host2 -json
```

3. Use the following command to disable the pbs.master role for the fabric to be imported:

```
maprcli config save -values {cldb.pbs.global.master:0} -json
```

If any security policies have been created on the fabric to be imported, they must be manually re-created on the importing fabric after the import operation is completed. To re-create the policies, refer to [Administering Security Policies](#) on page 1229.

4. On the cluster to be imported, create a tar ball of the fabric directory:

```
/opt/mapr/installer/ezdfaas/deployments/<cluster-name>
```

5. Copy the contents of the tar ball to the importing cluster's /opt/mapr/installer/ezdfaas/deployments directory. Extract the contents, and be sure to delete the .tar file:

6. Obtain the SSO configuration from the importing fabric, and configure it on the fabric to be imported:

- a. Use the following command to fetch the SSO parameters from the importing fabric:

```
maprcli cluster getssoconf -json
```

For example:

```
maprcli cluster getssoconf -json
{
  "timestamp":1699432649586,
  "timeofday":"2023-11-08 12:37:29.586 GMT-0800 AM",
  "status":"OK",
  "total":1,
  "data":[
    {
      "issuerendpoint":"https://<hostname>:443/realms/master",
      "providername":"keycloak",
      "clientid":"edf-client",
      "clientsecret":"<secret>"
    }
  ]
}
```

- b. Obtain the SSO certificate from the importing fabric's /opt/mapr/keycloak/conf/.crt, and use it to set the SSO configuration information for the fabric to be imported. Use the following command:

```
maprcli cluster setssoconf -issuerendpoint "https://:8443/realms/
TestReallm" -providername keycloak -clientid
edf-client -clientsecret <secret> -certfile -json
```

- c. Restart the mapr-apiserver services.

```
maprcli node services -name apiserver -action restart -nodes
host1,host2 -json
```

- d. Wait for a minute to ensure that the SSO configuration is active, then try signing in to the UI:

```
https://<apiserver>:8443/app/dfui
```

You should be redirected to the Keycloak sign-in screen.

7. Use the Data Fabric UI to complete the **Import** operation as described in the next section.

Completing the Import Operation by Using the Data Fabric UI

Use the following steps to complete the import operation:

1. Log on to the Data Fabric UI as a Fabric Manager.
2. Click the All resources icon on the left panel.
3. Select the **Import fabric** option from the **Actions** dropdown. The **Import fabric** menu appears.
4. Specify the current **Name** of the fabric to be imported. Do not change the name of the fabric to be imported.
5. Specify the **Public IP address** of the API server of the fabric to be imported.

6. Specify the port of the API server for the fabric to be imported.
7. Click **Import**.
8. Once the **Import** operation is finished, ensure that the imported fabric is part of a cluster group and the fabric is listed as part of the global namespace.

Configuring Keycloak as Identity Provider for SSO

Describes how to configure an external Keycloak server to interface with HPE Data Fabric for single sign-on (SSO) during the first fabric creation.

About this task

You can configure an externally installed Keycloak server as your identity provider that can be used for single sign-on to HPE Data Fabric.

As the provider is Keycloak, the provider name value is pre-filled as **keycloak**.

To connect to Keycloak, you must have the following details handy.

- The provider URL, that is, the URL of the Keycloak server.
- The client ID, that is, the identifier that enables communication between the Data Fabric and the SSO provider
- The client secret, that is, the key that is used to authenticate a client with the Keycloak server.
- The self-signed certificate from the SSO provider.

TIP: The provider URL and the client ID is available on the **SSO setup** page, once the fabric is installed and can be modified at any time from the **SSO setup** page.

Follow the steps given below to configure an external Keycloak server as the identity provider for Data Fabric.

Select type

☐ Install keycloak
☐ Do not install keycloak
☒ **Configure keycloak**

Provider name*

keycloak

Provider URL*

https://10.10.110.10

Client ID*

edfclient

Client secret*

..... 

Certificate file path*

path/to/keycloak-certificate-file

Procedure

1. Enter the **Provider URL**.
2. Enter the **Client ID**.
3. Enter the **Client secret**.
4. Enter the path for the self-signed certificate file.

Administering Nodes

Describes the node management operations that you can perform using the Data Fabric UI.

A [node](#) is an individual physical or virtual machine that constitutes a fabric and runs one or more services related to the fabric.

Viewing Node Information

Describes how to use the Data Fabric UI to view the node status and other information on the **Nodes** tab.

You must be a fabric manager to view node information. In addition, node information is available only for on-premises fabrics; it is not available for cloud fabrics.

To view node information for an on-premises fabric:

1. Log on to the Data Fabric UI.

2. Click the All resources icon on the left pane, and check the table view.
3. Under the **Resource Name** column, click the fabric name for which you want to display node information.
4. Click the **Nodes** tab.

The node list table appears.

Adding a Node to On-premise Fabric

Describes how to add one or more nodes to an installed on-premises deployment by using the Data Fabric UI.

Adding nodes to an installed fabric can help in several ways. For example, you can add nodes to increase the total storage, redistribute resources, boost the compute capacity, or improve the availability of certain services. Adding nodes is sometimes referred to as a *scaling operation* because it allows you to scale the storage and performance of the fabric.

Limitations for Adding Nodes

Note the following limitations for adding nodes by using the Data Fabric UI:

- The Data Fabric UI supports adding nodes to both on-premises and cloud deployments. To add nodes to cloud deployments, such as AWS, Azure, and GCP, see [Adding a Node to a Cloud-based Fabric](#) on page 1129.
- You can use the Data Fabric UI to add nodes to an on-premises deployment only if the fabric is running release 7.7.0 or later.
- You cannot use the Data Fabric UI to add nodes to a cluster that was created using a method other than the seed node installation method.

To add nodes to a non-seed node cluster, you must use the Installer for non-seed node platforms or manual steps. See [Extending a Cluster by Adding Nodes](#) or [Adding Nodes to a Cluster](#).

- If the fabric has fewer than three nodes, adding nodes requires restarting ZooKeeper and Warden on one node at a time on the previously installed nodes. During the restart phase, access to each node is lost temporarily. If the fabric has three or more nodes, the restart is not needed.
- On any given fabric, only one scaling operation can be done at a time. If a scaling operation is already in progress, you cannot initiate another scaling operation on the same fabric. However, scaling operations can be performed at the same time on different fabrics belonging to the same global namespace.
- **Add node** operation is not possible when an upgrade operation is in progress. In addition, <upgrading data fabric> is not supported when an **Add node** operation is in progress.
- The Data Fabric UI does not currently provide an option to remove a node from a fabric.

Prerequisites for Adding Nodes

Note the following prerequisites for adding nodes by using the Data Fabric UI:

- To add nodes, you must have fabric manager [credentials](#).
- There is no restriction on the size of a fabric for adding nodes. You can add nodes to any fabric, including a one-node fabric.
- Adding nodes to an on-premises installation requires that you provide the host nodes *before* starting the scaling operation. There is no restriction on the number of nodes you can add, but the nodes must meet certain requirements.

Steps for Adding Nodes

Use the following steps to add nodes:

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Under the **Resource Name** column, click the fabric name for which you want to add nodes. The **Fabric details** are displayed.
4. Click the **Nodes** tab. For more information, see [Viewing Node Information](#) on page 1126.
5. Click **Add node**. The **Add node** side drawer appears.
6. Fill in the required node parameters:

For this parameter . . .	Do this
SSH credentials*	Enter your Username for SSH access to the node. Enter your Password .
Nodes*	Enter the fully qualified domain name (FQDN) of the first node you want to add. To add another node, click + Add node , and enter the next FQDN. If you enter a node name by mistake, click the trash can () icon to remove it.
Network settings	<p>If necessary, specify the optional network settings:</p> <p>EDF subnet – Specify one or more comma-separated subnet masks. For example:</p> <p>10.10.15.0/24, 10.10.16.0/24</p> <p>EDF external – Specify a comma-separated list of tuples of host names and external IP addresses. For example:</p> <p>node1:1.1.1.1, node2:1.1.1.2, node3:1.1.1.3</p> <p>For more information about the network settings, see Using the MapR Subnet and MapR External Advanced Options.</p>

*This field is mandatory.

7. Click **Add node**. The Data Fabric UI displays a **Nodes in scale operation** table that includes a **Status** column.
8. Check the status of the scaling operation:

To	Do this
View the status for a single node	<p>Hold your cursor over the information icon () . The icon is displayed when the node status is Installing. Hovering over the tooltip displays the installation status as a percentage.</p> <p>Or, in the Actions column, click the ellipsis for a node, and select View progress to display Node details information.</p>
View the status for all nodes	Click View progress .

If the scaling operation is successful, the Data Fabric UI displays a success message, and the table of active nodes is updated.

Troubleshooting the Scaling Operation

If the scaling operation fails, the Data Fabric UI displays a status of **Failed** in the **Nodes in scale operation** table. To obtain more information:

1. Examine failure data for the entire scaling operation by clicking **View progress** above the table. Or, click the ellipsis () in the **Action** column, and select **View progress** (for a single node).
2. If possible correct the root cause of the failure.
3. Click **Reinitiate** to retry adding the node. The original side drawer is displayed, allowing you to make any needed configuration changes.
4. Click **Reinitiate**.

If you are not able to resolve the issue that caused the scaling operation to fail, contact [HPE Support](#).

Related maprccli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprccli` commands.

- `installer clusterscale`
- `installer clusterscalestatus`

Adding a Node to a Cloud-based Fabric

Describes how to add one or more nodes to a cloud deployment by using the Data Fabric UI.

Adding nodes to a cloud-deployed fabric can help in several ways. For example, you can add nodes to increase the total storage, redistribute resources, boost the compute capacity, or improve the availability of certain services. Adding nodes is sometimes referred to as a *scaling operation* because it allows you to scale the storage and performance of the fabric.

Limitations for Adding Nodes

Note the following limitations for adding nodes by using the Data Fabric UI:

- You can use the Data Fabric UI to add nodes to a cloud deployment only if the fabric is running release 7.8.0 or later.
- Only one **Add node** operation can be done at a time. Multiple **Add node** operation is not allowed (**Add node** button is disabled when a scaling operation is already in progress).
- Scaling operations can be performed at the same time on different fabrics belonging to the same global namespace.
- **Add node** operation is not possible when an upgrade operation is in progress. Similarly, the upgrade operation is not supported when an **Add node** operation is in progress.
- Each node has a default host name, such as `aws_instance`, `gcp_instance`, or `aws_instance`. For example, a scale operation to add two nodes on AWS may have default name as `aws_instance1`, `aws_instance2` in the UI.
- During each scale operation, maximum number of nodes you can add, is equal to the number of nodes you already have in the fabric. For example, If a fabric has five nodes already, you can scale the fabric by one node to five nodes maximum, and not more than five nodes. However, you can add more nodes by performing the scaling operation again.
- The Data Fabric UI does not currently support scaling down (removing a node from) a fabric.

Prerequisites for Adding Nodes

Note the following prerequisites for adding nodes by using the Data Fabric UI:

- To add nodes, you must have logged in with fabric manager [credentials](#).
- You must have the account credentials of the cloud service that you want to scale.

Steps for Adding Nodes

Use the following steps to add nodes:

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Under the **Resource Name** column, click the fabric name for which you want to add nodes. The **Fabric details** are displayed.
4. Click the **Nodes** tab. For more information, see [Viewing Node Information](#) on page 1126.
5. Click **Add node**. The **Add node** side drawer appears. Depending on the cloud provider of the fabric, such as AWS, Azure, or GCP, respective fields appear.
6. Use the one of the suitable table (GCP, Azure, or AWS) to fill in the required node parameters:

Table

For this parameter . . .	Do this
GCP access credentials*	Click on Select file* , and drag and drop the Service account key file .  NOTE: If you do not have a Service account key file already, you can first create one in Google Cloud, and then upload the file.
Fabric details	<ul style="list-style-type: none"> • Node* - Select the number of nodes to be added.

*This field is mandatory.

Table

For this parameter . . .	Do this
Azure access credentials*	Enter the following mandatory information: <ul style="list-style-type: none"> • Subscription ID* • Tenant ID* • Client ID* • Client Secret*
Fabric details	<ul style="list-style-type: none"> • Node* - Select the number of nodes to be added.

*This field is mandatory.

Table

For this parameter . . .	Do this
AWS access credentials*	Enter the following mandatory information:  NOTE: User must have AmazonEC2FullAccess permission. <ul style="list-style-type: none"> • Access Key* • Secret Key*
Fabric details	<ul style="list-style-type: none"> • Node* - Select the number of nodes to be added.

*This field is mandatory.

- When you have filled in the required node parameters, click **Submit**.
- Click **Add node**. The Data Fabric UI displays a **Nodes in scale operation** table that includes a **Status** column.
- Check the status of the scaling operation:

To	Do this
View the status for a single node	Hold your cursor over the information icon (ⓘ). The icon is displayed when the node status is Installing . Hovering over the tooltip displays the installation status as a percentage. Or, in the Actions column, click the ellipsis for a node, and select View progress to display Node details information.
View the status for all nodes	Click View progress .

If the scaling operation is successful, the Data Fabric UI displays a success message, and the table of active nodes is updated.

Troubleshooting the Scaling Operation

If the scaling operation fails, the Data Fabric UI displays a status of **Failed** in the **Nodes in scale operation** table. To obtain more information:

- Examine failure data for the entire scaling operation by clicking **View progress** above the table. Or, click the ellipsis (⋮) in the **Action** column, and select **View progress** (for a single node).
- If possible correct the root cause of the failure.
- Click **Reinitiate** to retry adding the node. The original side drawer is displayed, allowing you to make any needed configuration changes.
- Click **Reinitiate**.

If you are not able to resolve the issue that caused the scaling operation to fail, contact [HPE Support](#).

Related maprccli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprccli` commands.

- `installer clusterscale`

- [installer clusterscalestatus](#)

Related concepts

[Adding a Node to On-premise Fabric](#) on page 1127

Describes how to add one or more nodes to an installed on-premises deployment by using the Data Fabric UI.

Restarting Nodes

Restart a node from the Data Fabric UI.

About this task

You can restart a node on an on-premise fabric or a cloud-based fabric when there is a change in the configuration, and the node requires a restart due to the configuration changes.

When you restart a node, it is advisable not to carry out any other CRUD operation on the fabric. Performing any other CRUD operation on a fabric during a node restart would have unexpected outcomes.

Only one node from a fabric can be restarted at a time.

Similarly, you cannot restart a node when another CRUD operation is running on a fabric.

Follow the steps given below to restart a node.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All Resources icon on the left pane, click the table view icon.
3. Under the **Resource Name** column, click the fabric name for which you want to remove nodes. The **Fabric details** are displayed.
4. Click the **Nodes** tab.
5. Click the ellipsis () in the **Actions** column, and then click **Restart node** .

Results

The node restarts in a few minutes' time.

Removing a Node from an On-premise Fabric

Describes how to remove one or more nodes from an on-premise fabric deployment by using the Data Fabric UI.

Removing nodes from an installed fabric is necessary in many situations such as:

- To remove the nodes that have reached end of life.
- To perform maintenance activity such as applying security patches or upgrading the operating system.
- To perform some activities mandated by organization that need node removal.
- To scale down a fabric that was scaled up to meet a temporary requirement of increased storage and compute.

Prerequisites

IMPORTANT: To avoid loss of data, remember to back up the data from the node, before you remove the node.

For on-prem fabrics, you can choose a node to remove. Ensure that the node satisfies the criteria mentioned in this section.

Following are the prerequisites for node removal.

- You cannot use the Data Fabric UI to remove nodes from a cluster that was installed using a method other than the seed node installation method.
- You must have fabric manager [credentials](#) to remove a node.
- A fabric requires a minimum of two CLDB and Zookeeper hosts at all times. A node cannot be removed if this condition is breached due to the node removal.

NOTE: If you remove a control node (that have CLDB and ZooKeeper running), cluster will be reconfigured with the remaining CLDBs, and Warden will be restarted on each node of the fabric, after removing the control node. Before proceeding to remove a CLDB master node, perform failover of CLDB master first, and then proceed with node removal.

- If the fabric running the node is the primary fabric in the global namespace, you cannot remove the node that runs the SSO Keycloak service.
- You cannot remove the node that has the installer host that has been used to configure the fabric or the current node that is being used for node removal.
- You can remove a node only if the fabric has at least three nodes, excluding the node or nodes to be removed.
- You can remove a node only if the cluster storage consumption is less than 80 percent.
- On any given fabric, only one *Remove node* operation can be done at a time. If a remove node operation is already in progress, you cannot initiate another *add node* or *remove node* operation on the same fabric. However, multiple *remove node* operations can be performed at the same time on different fabrics belonging to the same global namespace.
- *Remove node* operation is not possible when an *upgrade fabric*, *remove fabric*, or *add node* operation is already in progress.

Steps for Removing Nodes from a Fabric

Use the following steps to remove nodes:

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Under the **Resource Name** column, click the fabric name for which you want to remove nodes. The **Fabric details** are displayed.
4. Click the **Nodes** tab. For more information, see [Viewing Node Information](#) on page 1126.
5. Click the ellipsis () in the **Action** column, and select **Delete** . The **Delete node** side drawer appears.
6. Fill in the following node parameters:

For this parameter . . .	Do this
SSH credentials*	Enter your Username for SSH access to the node. Enter your Password .

7. Optionally, turn on the **Skip host drain check** toggle, to skip checking if the data on the node has been drained before removing it, after three failed attempts to remove the node. The node drain check is skipped the fourth time, if there are three failed node removal attempts, and the node is removed without checking if the data from the node to be removed has been drained (that is, moved to another node on the same cluster).

8. Click **Delete**.

Results:

The Data Fabric UI displays **Deleting** in **Status** column for the node that is being deleted.

If the node removal/delete operation is successful, the Data Fabric UI displays a success message, and the table of active nodes is updated.

Related maprccli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprccli` commands.

- [installer clusterscalestatus](#)
- [installer clusterremovenode](#) on page 2534

Removing A Node from a Cloud-based Fabric

Describes the procedure to remove a node from a cloud-based fabric.

Prerequisites

You must have fabric manager [credentials](#) to remove a node.

ATTENTION: For a cloud-based fabric, Data Fabric auto-selects the node to delete, based on the prerequisites for node removal that are mentioned in this topic. Although you can choose to remove a node from a cloud-based fabric, you cannot select the node to be removed.

Data Fabric checks for the following prerequisites before removing a node from a cloud-based fabric.

- A fabric requires a minimum of two CLDB and Zookeeper hosts at all times. A node cannot be removed if this condition is breached due to the node removal.
- If the fabric running the node is the primary fabric in the global namespace, you cannot remove the node that runs the SSO Keycloak service.
- You cannot remove the node that has the installer host that has been used to configure the fabric or the current node that is being used for node removal.
- You can remove a node only if the fabric has at least three nodes, excluding the node or nodes to be removed.
- You can remove a node only if the cluster storage consumption is less than 80 percent.
- On any given fabric, you can remove one node at a time. If a remove node operation is already in progress, you cannot add a node to or remove a node from the same fabric. However, multiple remove node operations can be performed at the same time on different fabrics belonging to the same global namespace.
- You cannot remove a node when an upgrade fabric, a remove fabric, or an add node operation is in progress.
- You cannot remove a node if the node to remove hosts any of the following services, and if only one instance of the service exists for the fabric.
 - `mapr-zeppelein`

- `mapr-historyserver`
- `mapr-hbasethrift`
- `mapr-hivewebhcat`
- `mapr-hiveserver2`
- `mapr-hivemetastore`
- `mapr-hue`
- `mapr-hue-livy`
- `mapr-spark-thriftserver`
- `mapr-spark-historyserver`

About this task

Removing nodes from an installed fabric is necessary in many situations such as:

- To remove the nodes that have reached end of life.
- To perform maintenance activity such as applying security patches or upgrading the operating system.
- To perform some activities mandated by organization that need node removal.
- To scale down a fabric that was scaled up to meet a temporary requirement of increased storage and compute.

You can remove a node from a cloud-based deployment by using the Data Fabric UI for HPE Data Fabric version 7.10.0 or later.

NOTE: For a cloud-based fabric with EEP services, you cannot directly access the EEP or core services page from the Control System. Redirection fails because Data Fabric makes use of private hostnames while configuring the cloud fabric. Private hostnames are not publicly resolvable.

Follow the steps given below to initiate the removal a node from a cloud-based fabric.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Under the **Resource Name** column, click the name of the cloud-based fabric for which you want to remove a node.
4. Click the **Nodes** tab. For more information, see [Viewing Node Information](#) on page 1126.
5. Click the **Delete node** option.
6. Enter the cloud credentials specific to the public cloud provider on which your fabric is deployed. For instance, enter the access key ID and the secret key if you are deleting a node from a fabric deployed on AWS.

7. Optionally, turn on the **Skip host drain check** toggle, to skip checking if the data on the node has been drained before removing it, after three failed attempts to remove the node. The node drain check is skipped the fourth time, if there are three failed node removal attempts, and the node is removed without checking if the data from the node to be removed has been drained (that is, moved to another node on the same cluster).
8. Click **Delete**.

Results

The Data Fabric UI displays **Deleting** in **Status** column for the node that is being deleted. If the node removal is successful, the Data Fabric UI displays a success message, and the table of active nodes is updated.

Related maprccli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprccli` commands.

- [installer clusterscalestatus](#)
- [installer clusterremovenode](#) on page 2534

Viewing the Fabric Status

Describes how to view the fabric status.

About the All Resources Page

The **All resources** page shows the current status and software version for each fabric and allows you to perform certain fabric-level actions (subject to your role). These actions can include:

- Viewing fabric status and error information
- Viewing fabric access points
- Importing a fabric
- Creating a fabric
- Importing an external S3 server
- Importing an external NFS server
- Upgrading fabric software (if a new software version is available)
- Deleting a fabric
- Reinitiating (retrying) an upgrade operation

Viewing the Fabric Status

To view the fabric status:

1. Sign in to the Data Fabric UI.
2. Click the All resources icon on the left pane to access the **All resources** page.
3. View the list of resources along with the status in the graph view, by clicking the **Graph view** icon. The graph view is the default view. You can click the graph view icon to view resources in a graph view. Alternatively, click the **Table view** icon to display the resource table with fabric status values.

Fabric Status Information

Fabric status values include:

Status	Description
Active	An activation key has been added.
Deleting	Fabric removal, as described in Deleting a Fabric on page 1152, is currently in progress.
Expired	The activation key for the fabric is no longer valid.
Inactive	An activation key has not been added for the fabric.
Install Failed	There was a problem during installation, and the fabric was not successfully installed.
Installed	Fabric installation completed successfully.
Installing	Fabric installation is currently in progress.
Upgrade Failed	There was a problem during the software upgrade, and the fabric was not successfully upgraded.
Upgrading	A software upgrade is currently in progress.

Viewing Fabric Settings

Describes how to view and change the fabric settings, which include fabric auditing, data auditing, and gateway information.

About the Fabric Settings

Fabric settings currently include:

Setting	Default Value	Description
Fabric auditing	Off	Auditing of fabric-management operations and fabric administration.
Data auditing	Off	Auditing of data-access operations.
Gateway	N/A	The Gateway parameter is not currently supported. For table replication, generate a DNS record that specifies the location of the gateways in the fabric, which can copy and paste into the zone file for your domain. Source fabrics can look up gateways during table replication using this record. Before generating the record, ensure that you have configured gateways in your cluster.
Proxy configuration	No proxy configured	Enables the configuration of an https or http proxy for environments that have a proxy server.

Viewing the Fabric Settings

To view the **Fabric Settings** card:

1. Sign in to the Data Fabric UI.
2. Click the Fabric administration icon on the left pane.
3. Click the **Settings** tab.
4. Check the **Fabric Settings** card.

Changing the Fabric Settings

To change fabric settings:

To	Do this
Turn on fabric auditing	Click and drag the slider to the right.
Turn on data auditing	Click the Edit icon (✎), select On , and click Update.
Copy the gateway information to the clipboard	Click the the Copy icon (📋).
Configure the proxy	See Configuring a Proxy Server for Data Fabric Access to the Internet on page 1116.

Related reference

[Auditing Fabric and Fabric Data](#) on page 1228

Auditing in Data Fabric.

Viewing the Fabric Endpoint

Describes how to view the endpoint for a fabric on the Data Fabric UI.

Prerequisites

You must be a fabric manager to perform this operation.

About this task

You can view the endpoint for a fabric from the Data Fabric UI.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane.
3. On the table view, click the ellipsis under **Action** for the fabric whose endpoint you wish to view.
4. Click the **View access points** option.

Results

The fabric endpoint is displayed. The endpoint can be used to access the fabric and fabric resources. You can download the endpoint.

Viewing the Software Version

Describes several ways to identify the core software version for a fabric.

View the Software Version with User Information

To view the core software version:

1. Sign in to the Data Fabric UI.
2. In the upper right corner of the home screen, click the down arrow next to the user name. For example:

Viewing the Software Version with Fabric Details

To view the core software version:

1. Sign in to the Data Fabric UI.
2. Click the All resources icon on the left pane.
3. Click the **Table view** icon to display the resource table with status values.
4. Click the fabric name to display the fabric details page. The core software version is displayed as the **Build Version**:

Fabric details

Fabric ID	
Global namespace	GlobalNameSpace
Provider	OnPrem
Node IP addresses	View all
Build version	7.5.0.0.20231026222149.GA
NFS server root	View all
Object server storage endpoint	View all
Data at rest encryption	Enabled

Alarms

Error	Warning	Info
0	2	0

Generating S3 Access Keys for the Global Namespace

Describes how to obtain an S3 user access key and secret key that can be used to perform operations on S3 resources anywhere in the global namespace.

For the fabric manager you can generate and download a user access key and secret key. These keys facilitate command-line and programmatic (API) access to S3 resources for all fabrics in the namespace. For example, once you have generated the keys for the fabric manager, you can use MinIO client (mc) commands to set an alias for the fabric manager. Then you can use the same alias to perform operations on all fabrics in the namespace. For information about the supported mc commands, see [MinIO Client \(mc\) Commands](#).

You can generate the keys only twice for the same global namespace. More attempts to generate keys result in an error message.

Use these steps:

1. Sign in to your fabric as a fabric manager.
2. Click the All resources icon on the left pane.
3. Click the **Graph view**.
4. Click the icon for the global namespace.
5. Click **View access points**:

The **Access points** screen is displayed.

6. Click the **S3 servers** tab. The screen displays the Access keys and S3 server details:

Access points ×

GlobalNameSpace

NFS servers **S3 servers**

Access keys

i You can generate up to 2 keys.

No S3 access keys exist.
Once a key is generated, it will be displayed here.

Generate key

S3 server details

Default: `https://10.0.1.204:9000` 📄

External: `https://3.101.79.104:9000` 📄

`https://3.101.79.104:9000` 📄

Download

7. Click **Generate key**. A confirmation dialog box asks if you want to generate a new S3 key.
8. Click **Generate key**. A dialog box displays the access key and secret key information. For example:

Generate key ×

⚠️ Please save the credentials as you won't be able to view it again after you close this dialog.

Access key 📄

Secret key 📄

Download JSON **Done**

9. Click **Download JSON** if you want to download the keys for the global namespace as a JSON file.
10. Click **Download** if you want to download the S3 end points information as a JSON file.

Setting a Quota for a User

Set quota for an individual user.

About this task

You can set quotas for individual users via the Data Fabric UI.

The following quotas can be set.

- Advisory quota, which raises an alarm when the threshold is reached, but does not prevent further writes.
- Hard quota, which raises an alarm when the limit is reached and prevents further writes. which raises an alarm when the limit is reached and prevents further writes.

Advisory quota and hard quota can be expressed in megabytes (MB), gigabytes (GB), or terabytes (TB). GB is the default unit. The advisory quota must be less than the hard quota.

Follow the steps given below to set quota for a user.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Fabric administration icon on the left pane.
3. Select the fabric name from the **Select fabric** dropdown.
4. Click the fabric link for which the user quotas are to be set.
5. On the **Manage Access** tab, click the **Settings** tab.
6. Select the **users** option in the dropdown for **Quota by**.
7. Click **Edit fabric quotas** on the **Quota by** card.
8. On the **Edit Fabric Quotas** dialog box, enter the values for user advisory quota, user hard quota, group advisory quota and group hard quota. Change the unit, as required.
9. Specify the **Fabric reserve limit**.
10. Click **Update**.

Results

The specified quota is saved for the individual user.

NOTE: The default quota specified for the fabric applies to other groups, unless a group-specific quota is set for any other group on the fabric.

Setting a Quota for a Group

Set quota for an individual group.

About this task

You can set quotas for individual groups via the Data Fabric UI. This quota overrides the default group quota set for the fabric.

The following quotas can be set.

- Advisory quota, which raises an alarm when the threshold is reached, but does not prevent further writes.

- Hard quota, which raises an alarm when the limit is reached and prevents further writes. which raises an alarm when the limit is reached and prevents further writes.

Advisory quota and hard quota can be expressed in megabytes (MB), gigabytes (GB), or terabytes (TB). GB is the default unit. The advisory quota must be less than the hard quota.

Follow the steps given below to set quota for a group.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Fabric administration icon on the left pane.
3. Select the fabric name from the **Select fabric** dropdown.
4. Click the fabric link for which the user quotas are to be set.
5. On the **Manage Access** tab, click the **Settings** tab.
6. Select the **groups** option in the dropdown for **Quota by**.
7. Click **Edit fabric quotas** on the Quota by groups card.
8. On the **Edit Fabric Quotas** dialog box, enter the values for advisory quota, hard quota. Change the unit, as required.
9. Specify the **Fabric reserve limit**.
10. Click **Update**.

Results

The specified quota is saved for the individual group.

NOTE: The default quota specified for the fabric applies to other groups, unless a group-specific quota is set for any other group on the fabric.

Viewing Fabric-Related Metrics

Explains the various fabric-related metrics visible on the [Data Fabric UI](#) on page 1100.

About this task

You can view various useful fabric-related metrics on the [Data Fabric UI](#) on page 1100.

The metrics include data related to billing and storage consumption by fabric, storage usage by various users of the fabrics that are being monitored via the [Data Fabric UI](#) on page 1100, and the top fabrics nearing the total storage capacity.

Click any of the following links to view details about the fabric-related metrics that are visible on the Home Page of the [Data Fabric UI](#) on page 1100.

View Storage Consumption by User

View fabric storage consumption by users.

Prerequisites

- You must be a fabric manager or an infrastructure admin to perform this operation.
- Users and/or groups must have been created.

About this task

View how much storage is used by individual fabric users via the Data Fabric UI.

You can determine the fabric storage consumption trends by users on the fabrics that are being monitored via the Data Fabric UI.

Viewing fabric storage consumption trends by groups is available if groups have been defined on the Data Fabric UI.

The storage consumption by a user/group is aggregated storage size of volumes and topics owned by the user/group.

NOTE: Bucket storage consumption is not included as there is no concept of bucket owner in Data Fabric.

You can import a fabric to monitor the fabric usage via the Data Fabric UI. See [Importing a Fabric](#) on page 1122 for information importing fabrics.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Monitoring icon on the left pane.
3. Select the **user** option on the **Storage utilization by** card.

Results

You are able to view a list of all fabric users and/or groups, in the order of the storage utilization.

View System Resource Utilization by Fabric

View system resource utilization for fabric.

Prerequisites

You must be a fabric manager or an infrastructure admin or a fabric user to perform this operation.

About this task

View a graphical representation of CPU utilization and memory utilization by fabric for the selected time duration.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Monitoring icon on the left pane, and check the **System resources** card to view the CPU and memory utilization by fabric.
3. Select the fabric and the time duration for which you wish to view the CPU and memory utilization of the fabric.

Results

For an infrastructure admin or a fabric manager, the CPU and memory utilization is seen as shown in the following image.

Fabric utilization

Name	CPU(Cores)	Memory(GB)
venkat_cluster214	1 of 32 (3%)	51 GB of 129 GB (38%)
venkat_cluster215	4 of 32 (13%)	52 GB of 129 GB (38%)
cluster-onprem-199	3 of 40 (8%)	47 GB of 129 GB (35%)

For a fabric user, you can view the system utilization by the fabric during the selected time duration in a graphical format. The following image shows CPU and memory utilization by the two selected fabrics for the last 6 hours.

**View Top Fabrics by Storage Capacity**

View up to top five fabrics by consumption of the available storage capacity.

Prerequisites

- You must be a fabric manager or an infrastructure admin to perform this operation.
- One or more fabrics must have been created on or imported into Data Fabric.

About this task

View the top fabrics that have consumed maximum of the total storage available to the fabric.

You can use this data to understand what fabrics are nearing the total storage capacity available to the fabric.

Procedure

1. Log on to the Data Fabric UI .
2. Click the Monitoring icon on the left pane
3. Scroll down to see the **Fabric Storage** card.

Results

You are able to see up to five fabrics that have consumed maximum storage capacity out of the available storage capacity available to the individual fabrics. If you have clicked the fabric area on the **Fabric Storage** card, you are navigated to the Resource page to be able to view the fabric resources.

Setting Default Quotas for Users/Groups

Set default values for user and group quotas on a fabric via the Data Fabric UI.

Prerequisites

You must be a fabric manager to edit user quotas and group quotas for a fabric.

About this task

Quotas limit the disk space used by a volume or an entity such as a user or a group. A volume quota limits the space used by a volume. A user/group quota limits the space used by all volumes owned by a user or group. These quotas work on tenant volumes as well.

You can set hard quota and advisory quota defaults for users and groups. When a user or group is created, the default quota and advisory quota apply unless overridden by specific quotas. Quotas can be specified in mega bytes (MB), gigabytes (GB), terabytes (TB), petabytes (PB), exabytes (EB), and zettabytes (ZB).

- User quota is the total space allocated to user on fabric.
- User hard quota is the total space allocated to user on fabric.
- Group quota is the total space allocated to group on fabric.
- Group hard quota is the total space allocated to group on fabric.
- Fabric reserve limit is the percentage of the total cluster capacity to allocate for the volumes on the cluster.

The size of a disk space quota is expressed in terms of the actual data stored from the user's point of view. Only post-compression data blocks are counted, and snapshot and replica space do not count against quotas. For example, a 10G file that is compressed to 8G and has a replication factor of 3 consumes 24G (3*8G), but charges only 8G to the user or volume's quota.

Follow the steps given below to set default quotas for users and/or groups.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All Resources icon on the left pane.
3. Click the table view icon to see a tabular view of the resources.
4. Click the fabric name under the **Resource Name** column for which you wish to set the default user quota and/or group quota.
5. Click **Settings**. Click the pencil/edit icon next to the **Default quota**.
6. On the **Edit Fabric Quotas** dialog box, enter the values for user quota, user hard quota, group quota and group hard quota. Change the unit, as required.
7. Specify the **Fabric reserve limit**.
8. Click **Update**.

Results

The user quota, group quota, and fabric reserve limit specified for the fabric are saved. You can view the fabric default user quota and group quota on the **Settings** tab for the fabric.

You may choose to specify quotas for individual users and/or groups. Such values override the default user quota and group quota for the respective users and/or groups. See [Setting a Quota for a User](#) on page 1141 for details.

Viewing the Fabric Service Status

View status of various services running on a fabric.

Prerequisites

- You must have permissions to access and view the fabric details.

About this task

A fabric functions as a set of core services and monitoring services that run in the background. You can view the status of the services on the Data Fabric UI to determine if the services are running or they have stopped. This can be useful in preliminary troubleshooting of the fabric operation.

Use the following steps to view fabric service status.

Procedure

1. Log on to the Data Fabric UI
2. Click the All resources icon on the left pane.
3. Click the fabric name under the **Resource Name** column.
4. Navigate to the **Services** tab for the fabric.

Results

The details about the various fabric-related services along with the status of each service is visible on the **Services** tab.

NOTE: To stop, restart a service or an EEP service, you can navigate to the Managed Control System(MCS) from the Data Fabric UI. Click **MCS application** on the top right corner of the **Services** tab to open the Managed Control System in a new browser tab.

Adding a DEP Service

Add a DEP service to an existing fabric.

About this task

You can add a DEP service to an existing fabric by using the Data Fabric UI.

You can add multiple related services based on the auto-provisioning template or based on the custom option.

Procedure

1. Log on to the Data Fabric UI
2. Click the All resources icon on the left pane.
3. Click the fabric name under the **Resource Name** column.
4. Navigate to the **Services** tab for the fabric.
5. Click **Add service**.
6. Select the Auto-provisioning template for the DEP service to install on or add to the fabric.
7. Click **Database setup** and select the appropriate database option, if you have selected a template that installs DEP components related to the Hive Metastore. Enter the SSH credentials if you have selected an option other than the embedded database.
8. Click **Review** and review the service to add to the fabric.
9. Click **Submit** to add the service related to the selected auto-provisioning template.

Results

The service related to the selected auto-provisioning template is added to the fabric and is visible under the **Services** tab for the fabric.

Upgrading the DEP Version

Upgrade the DEP version installed on the fabric.

About this task

You can upgrade to a latest DEP version on a fabric by using the Data Fabric UI.

Procedure

1. Log on to the Data Fabric UI
2. Click the All resources icon on the left pane.
3. Click the fabric name under the **Resource Name** column.
4. Navigate to the **Services** tab for the fabric.
5. Click **Upgrade DEP version**.
6. Select the version to upgrade to.
7. Enter the **SSH credentials**, that is, the **Username** and the **Password**.
8. Click **Upgrade**.

Results

The DEP version on the fabric is upgraded to the selected version.

Deleting a DEP Service

Delete one or more DEP services installed on a fabric.

About this task

You can remove or delete a DEP service from a fabric by using the Data Fabric UI.

Procedure

1. Log on to the Data Fabric UI
2. Click the All resources icon on the left pane.
3. Click the fabric name under the **Resource Name** column.
4. Navigate to the **Services** tab for the fabric.
5. Click **Delete service**.
6. Select the service to delete from the list of installed services.
7. Type DELETE in the Enter DELETE text box.
8. Click **Delete** to confirm the permanent deletion of the selected services from the fabric.

Results

The selected services are permanently deleted from the fabric.

View Capacity Usage by User on Fabric

Describes how to check the capacity used by various internal volumes, buckets, topics, and binary tables created by the user that is logged in to the Data Fabric UI.

About this task

When you are logged in to the Data Fabric UI, you can view the total capacity for a fabric that is used up by the data stored on the volumes, buckets, topics, and binary tables created by you.

NOTE: The capacity displayed on the **My Capacity** card is related to the storage resources on the selected fabric only. The capacity displayed on the Data Fabric UI is exclusive of any resources such as volumes, buckets, topics, binary tables that you might have created on an external NFS server or external S3 server that has been added to the global namespace.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane.
3. Check the **My Capacity** card.
4. Select the fabric for which you wish to view the storage capacity that is used up by the volumes, buckets, topics, and binary tables that you have created. Alternatively, select all fabrics if you wish to view the capacity usage on your fabric resources for all fabrics.

Results

You are able to view the total capacity usage under **Total**, along with a categorized break-up of the storage capacity used up by the volumes, buckets, topics, and binary tables created by you on the selected fabric, or collectively for all fabrics if you have chosen to view the data for all fabrics.

SSH Access to a Cloud-Based Fabric

Describes how to obtain a fabric-specific .pem file that enables SSH access to a cloud-based fabric.

Command-line access to cloud-based fabrics (AWS, Azure, or GCP) requires you to download a fabric-specific .pem file. The Data Fabric UI makes it easy to download the file.

Note these considerations for downloading the .pem file:

- Only a user with the Fabric user or Fabric Manager role (or fc access) can use the **Download SSH keys** command.
- To connect to the fabric, you must provide the public IP address or public DNS name of any cloud fabric node. The public IP address or public DNS name are contained in the URL that you use to access the Data Fabric UI. The URL was provided when you performed the seed node installation to create your first fabric.
- SSH access to fabrics should only be used for troubleshooting operations under the supervision of HPE support personnel. SSH access should not be used for daily operations.

Use these steps to download the .pem file:

1. Sign in to the Data Fabric UI.
2. Click the All resources icon on the left pane.
3. Click the Table view icon.
4. Under the **Action** column, click the ellipsis ().

5. Click **Download SSH key**. The Data Fabric UI downloads the .pem file as <fabric_name>_key.pem.
6. If necessary, copy the file to the workstation that you will use to ssh to the fabric. Suppose you copy the file to /root/myfabric-keypair.pem. Remember the path to that location.
7. Reset the permissions on the downloaded .pem file to 0400:

```
chmod 0400 <pem-file-name>
```

8. Use one of the following commands to connect to the fabric:

AWS or GCP

```
ssh -i "<pem-file-name>" rocky@<public-IP-addr-or-public-DNS-name>
```

Azure

```
ssh -i "<pem-file-name>" mapr@<public-IP-addr-or-public-DNS-name>
```

Restarting a Fabric

Describes how to restart a fabric by using the Data Fabric UI.

About this task

When there are changes in the fabric configuration, you would need to restart the fabric.

You can restart a fabric that is a part of your global namespace by logging in to the same fabric or another fabric in the global namespace.

It is a good idea to close the browser after logging out.

The fabric restarts in a few minutes' time. To access the restarted fabric, you must re-login to the Data Fabric UI after the fabric restart.

IMPORTANT: CRUD operations are disallowed on a fabric when the fabric is in the process of restarting. Do not perform any CRUD operations on a fabric before the fabric restarts successfully.

Procedure

1. Sign in to the Data Fabric UI.
2. Click the All resources icon on the left pane.
3. Click the Table view icon to display the resource table.
4. Click the fabric name link for the fabric to restart. The fabric name is seen under the **Resource Name** column.
5. On Fabric Details page, click **Actions** seen on the top right side of the tab.
6. Click the **Restart fabric** option under **Actions**.
7. Click **Continue** to confirm fabric restart.

Results

The fabric restarts in a few minutes.

Enabling IPv6 for a Fabric

Describes how to enable IPv6 communication for an on-premise fabric.

Prerequisites

The underlying hardware that hosts Data Fabric must have a network interface card (NIC) that supports IPv6 addressing. This means, all fabric nodes must have the IPv6 compatible hardware.

About this task

You can enable IPv6 on an on-premise fabric.

Data Fabric can communicate with clients over IPv6 addressing. Inter-cluster traffic and intra-cluster traffic over IPv6 connections is supported with IPv4 compatibility.

CAUTION: Enabling IPv6 is an irreversible operation. You must restart the fabric manually, after the update is complete.

See [IPv6 Support in Data Fabric](#) on page 3532 for details on IPv6 support.

You can enable IPv6 network communication for a fabric by using the Data Fabric UI.

Follow the steps given below to enable IPv6 communication

Procedure

1. Log on to the Data Fabric UI.
2. Click the Fabric Administration icon on the left pane.
3. Select the fabric from the fabric dropdown for which you wish to enable IPv6 communication.
4. Click the **Enable IPv6** link.
5. Click **Update** to enable IPv6 on the fabric.

Deleting a Fabric

Delete a remote fabric from the global namespace.

Prerequisites

You must be a fabric manager to delete a fabric.

You must delete fabrics one at a time. You cannot delete multiple fabrics at the same time.

To delete a remote fabric, you must have logged in with your single sign-on credentials.

About this task

A local fabric is the fabric by which you are logged onto the Data Fabric UI. Any fabric, other than the local fabric, that has been added to the global namespace, is a remote fabric.

You can delete a remote fabric via the Data Fabric UI. You cannot delete a local fabric. If no remote fabrics are present, the **Delete** command is not available.

CAUTION: When you delete a fabric, the fabric is uninstalled, and any running instances of the fabric are destroyed. The data on a fabric becomes inaccessible when you delete the fabric. Ensure that you do not need the data on the fabric or the required data is backed up, before you delete the fabric.

Follow these steps to delete a fabric:

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane.

3. Click the Table view icon to display the resource table.
4. Click the ellipsis under **Actions** for the fabric to delete from the global namespace.
5. Click **Delete**. Confirm the fabric deletion.

Results

The fabric is deleted, removed, and uninstalled from the global namespace.

Administering Identities

This section describes the operations you can perform as an SSO user on identities, that is, IAM policies, SSO users, SSO groups, and roles for the HPE Data Fabric.

Only SSO users can access and use the identity management feature by using the Data Fabric UI.

You can assign SSO users, SSO groups, and identity access management (IAM) policies to a role.

NOTE: The creation and management of SSO user and SSO group is done from the SSO provider console. See your SSO provider documentation for details.

See the individual section about roles, users, groups, IAM policies for details about managing these identities.

About Roles

Describes roles in Data Fabric

A role comprises SSO users and/or SSO groups, along with the associated permissions on various Data Fabric resources.

The types of roles in Data Fabric are as follows:

- Pre-defined roles

NOTE: Only pre-defined SSO provider roles are recognized and used by the Data Fabric UI

- User-defined roles

An IAM policy can be assigned to or tagged to a user-defined role.

You can create and manage user-defined roles using the Data Fabric UI.

Pre-defined Roles

The pre-defined roles are as follows:

- Infrastructure administrator
- Fabric manager
- Fabric user or developer

Following are the characteristics of pre-defined roles.

- Predefined roles are made available as a part of the fabric deployment process, and stored in SSO service provider.
- Pre-defined roles have a fixed set of permissions.
- Pre-defined role are available on successfully deploying the first fabric.
- You cannot modify or delete pre-defined roles.

See [Pre-defined Roles and Associated Permissions](#) on page 1154 for the permissions assigned to each of the pre-defined roles.

User-defined Roles

A user-defined role is an identity that is associated with [IAM policies](#) and one or more SSO users and/or SSO groups in Data Fabric.

Following are the characteristics of user-defined roles:

- You can create and manage user-defined roles in Data Fabric.
- You can create user-defined roles after fabric deployment.
- You can create, modify, and delete user-defined roles, as required.
- You can define permissions in user-defined roles through IAM policies.

Pre-defined Roles and Associated Permissions

This page describes the roles supported by the HPE Data Fabric platform.

Roles and Permissions When SSO Is Configured

SSO-configured fabrics support the following pre-defined roles:

Role	Permissions	Corresponding ACL Permission Code ¹
Infrastructure Admin	Permission to log in and start or stop services	login, ss
Fabric Manager	Full control of the fabric, create volume permission, and login permission ²	login, cv, cp, fc
Fabric User	Login permission ² and create volume permission	login, cv, cp

¹Shows the equivalent access control list (ACL) permission code for the HPE Data Fabric – Customer Managed cluster. For more information, see [Security Policy Permissions](#) on page 1240 and [Creating Cluster-Level ACLs](#).

²The login user can log in to the Data Fabric UI and issue commands. Includes read access for existing objects.

Resource Actions Supported for the Roles

The following table shows the create, delete, and modify actions that each role can perform on various resources:

Role	Resource	Create	Delete	Modify
Fabric Manager	Fabric	Allow	Allow	Allow
	Volumes	Allow	Allow	Allow
	Buckets	Allow	Allow	Allow
	Directories	Allow	Allow	Allow
	User	Allow	Allow	Allow
	Accounts	Allow	Allow	Allow
	Groups	Allow	Allow	Allow
	S3 Keys	Allow	Allow	Allow
	Objects	Allow	Allow	Allow
	Security Policies	Allow	Allow	Allow
	Storage Policies	Allow	Allow	Allow
	Storage Tiers / Remote Targets	Allow	Allow	Allow
	SMTP Configuration	Allow	Allow	Allow
	IAM Policies	Allow	Allow	Allow
	User-defined role	Allow	Allow	Allow
Infrastructure Admin	Resource	Create	Delete	Modify
	Fabric	Deny	Deny	Allow
	Volumes	Deny	Deny	Deny
	Buckets	Deny	Deny	Deny
	Directories	Deny	Deny	Deny
	User	Deny	Deny	Deny
	Accounts	Deny	Deny	Deny
	Groups	Deny	Deny	Deny
	S3 Keys	Allow	Allow	Allow
	Objects	Deny	Deny	Deny
	Security Policies	Deny	Deny	Deny
	Storage Policies	Deny	Deny	Deny
	Storage Tiers / Remote Targets	Deny	Deny	Deny
	SMTP Configuration	Deny	Deny	Deny

Role	Resource	Create	Delete	Modify
Fabric User	Resource	Create	Delete	Modify
	Fabric	Deny	Deny	Deny
	Volumes	Allow	Allow	Allow
	Buckets	Allow	Allow	Allow
	Directories	Allow	Allow	Allow
	S3 Keys	Allow	Allow	Allow
	Objects	Allow	Allow	Allow
	Security Policies	Allow	Allow	Allow
	Storage Policies	Allow	Allow	Allow
	Storage Tiers / Remote Targets	Allow	Allow	Allow
	SMTP Configuration	Deny	Deny	Deny

Displaying Role Information

To display role information for the currently signed-in user:

1. Sign in to the Data Fabric UI.
2. In the upper right corner of the home screen, click the down arrow next to the user name. For example:

Limitation for Non-SSO Users

SSO users with sufficient credentials can view and manage resources on all fabrics. Non-SSO users can view and manage resources only on the fabric to which they are signed in. Non-SSO users cannot view or manage resources on other fabrics. The Data Fabric UI does not display these resources to non-SSO users because the UI cannot connect to other fabrics without the same login information.

Creating a Role

Describes how to create a user-defined role.

Prerequisites

The following prerequisites must be satisfied before you can create a user-defined role.

- You must be a fabric manager to be able to create a user-defined role.
- Single sign-on must be enabled to Data Fabric.

About this task

By default, Data Fabric has pre-defined roles that can be assigned to SSO users and SSO groups in Data Fabric.

If you need a user-defined set of permissions to apply to SSO users or SSO groups, you can configure user-defined roles and associate such roles with the required set of users.

A user-defined role can be attached to one or more SSO users and/or groups.

NOTE: Although you can create a role without associating IAM policies and users/groups with the role, it is a best practice to create related users/groups and IAM policies, before you create a role.

A user-defined role must have a unique name.

User-defined roles are shared across all fabrics in a global namespace.

NOTE: User-defined roles that are created using the Data Fabric UI are not visible on the Keycloak console.

Follow the steps given below to create a new role.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Security Administration icon > **Identity management** on the left pane.
3. Click the **Roles** tab.
4. Click **Create Role**.
5. Enter the **Name** and **Description** for the role.
6. Click **Add user and group** and then click **Add+** seen above **User** or **Group**.
7. Search and select one or more users and then click **Add** to add all selected users. Repeat in a similar way for groups, if you are adding groups.
8. Click **Assign Policy**. Search and select one or more IAM policies that the role is to be tagged with or associated with.
9. Click **Apply**.

Results

The new role is created. The newly created role is visible on the **Roles** card..

Viewing Roles

Describes how to view all roles in Data Fabric.

Prerequisites

You must be a fabric manager to perform this operation.

About this task

You can view all roles that have been configured in Data Fabric.

- The pre-defined and user-defined roles are displayed on the Data Fabric UI.
- Any roles created in the SSO provider, other than the predefined roles, are not visible on the Data Fabric UI.

- User defined roles that are created by using the Data Fabric UI or maprccli command line are listed on the Data Fabric UI.

Follow the steps given below to view a list of all existing roles.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Security Administration icon > **Identity management** on the left pane.
3. Click the **Roles** tab, to view a list of existing roles.

Results

A list of all existing roles, consisting of both pre-defined roles and user-defined roles, is displayed.

Editing a Role

Describes how to edit a user-defined role.

Prerequisites

You must be a fabric manager to perform this operation.

About this task

User-defined roles cannot be renamed.

You can modify the role description, the users and/or groups, and the IAM policies that are associated with a user-defined role.

Follow the steps given below to edit a user-defined role.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Security Administration icon > **Identity management** on the left pane.
3. Click the **Roles** tab.
4. Click **Create Role**.
5. On the list of roles, click the ellipsis under **Actions** for the user-defined role to edit.
6. Click **Manage role** to make changes to the user-defined role.
7. Make the required changes.
8. Click **Save**.

Results

The changes are saved and applied to the user-defined role.

Deleting a Role

Describes how to delete a role.

Prerequisites

You must be a fabric manager to perform this operation.

About this task

You can delete a user-defined role only when there is no user or group attached to the role.

NOTE: You cannot delete pre-defined roles.

Follow the steps given below to delete a user-defined role.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Security Administration icon > **Identity management** on the left pane.
3. Click the **Roles** tab.
4. Click **Create Role**.
5. On the list of roles, click the ellipsis under **Actions** for the user-defined role to delete.
6. Click **Delete** and type DELETE in the provided text area to confirm deletion.
7. Click **Save**.

Results

The selected user-defined role is deleted.

Assigning a Role to a User

Describes how to assign a role to a Data Fabric SSO user.

Prerequisites

You must be a fabric manager to perform this task.

About this task

You can assign one or more roles to an SSO user by using the Data Fabric UI.

Note the following with respect to role assignment from the Data Fabric UI.

- The Data Fabric UI supports the assignment of user-defined roles to SSO users/groups only. Assignment of SSO roles to SSO user/groups must to be done by using the SSO provider console or UI.
- The Data Fabric UI recognizes the assignment of roles to users/groups assignment made through SSO pre-defined roles only.
- Assignment of SSO users/groups to user-defined roles is facilitated but is not enforced, by using the Data Fabric UI.

To assign a role to a Data Fabric user, perform the following steps.

1. Sign in to the Data Fabric UI, and switch to the **Fabric manager** experience.
2. Click the Security Administration icon > **Identity management** on the left pane.
3. Click the **Roles** tab.
4. Click the pencil icon seen under **Actions** for the role that you wish to assign to the user.
5. Select **Manage Role**.
6. Click **Add user and group**.
7. Click **Add+** for Users and select the required user or users.
8. Click **Assign Policy** and then click **Apply**.

Results

The user is assigned the selected roles.

Assigning a Role to a Group

Describes how to assign a role to a SSO group via the Data Fabric UI.

Prerequisites

You must be a fabric manager to perform this task.

About this task

To assign a role to a SSO group, perform the following steps.

1. Sign in to the Data Fabric UI, and switch to the **Fabric manager** experience.
2. Click the Security Administration icon > **Identity management** on the left pane.
3. Click the **Roles** tab.
4. Click the pencil icon seen under **Actions** for the role that you wish to assign to a group.
5. Select **Manage Role**.
6. Click **Add user and group**.
7. Click **Add+** for Group and add the required group or groups.
8. Click **Assign Policy** and then click **Apply**.

Results

The selected role is assigned to the group.

Viewing a List of Users

Describes how to display a searchable list of SSO users that includes the names of the users and their roles.

The **Users** card can display only a small number of SSO users. If you are a fabric manager, you can also edit the roles for a user.

Note the following with respect to the Data Fabric UI:

- The **Users** card and the **User Identity** tab display user information available through the SSO provider. (Keycloak is currently the only supported SSO provider).
- Non-SSO users are not listed here.
- Only pre-defined roles that are assigned to SSO users are displayed on the **Users** card or the **User Identity** tab. A user-defined role assigned to an SSO user is not visible on the **Users** card or the **User Identity** tab.

To display the full list of SSO users:

1. Sign in to the Data Fabric UI.
2. Click the Security Administration icon > **Identity management** on the left pane.
3. Click the **Users** tab.
4. The list of SSO users is displayed.

Viewing a List of Groups

Describes how to display a searchable list of all SSO groups that includes the names of the groups and their roles.

Prerequisites

You must be a fabric manager to perform this task.

About this task

The **Groups** card can display up to five SSO groups on the Groups card.

Note the following with respect to the Data Fabric UI:

- The **Groups** card and **Group Identity** tab display SSO user and SSO group information only.
- Only pre-defined roles are displayed on the **Groups** card and **Group Identity** tab. Any user-defined roles are not visible here, even if they are assigned to SSO users/SSO groups.

To display the full list of SSO groups, perform the following steps:

1. Sign in to the Data Fabric UI, and switch to the **Fabric manager** experience.
2. Click the Security Administration icon > **Identity management** on the left pane.
3. Click the **Groups** tab.

Results

The list of SSO groups is displayed.

Administering IAM Policies

Provides an overview of IAM policies in Data Fabric.

Identity Access Management Policy

IMPORTANT: An IAM policy can be assigned to a user-defined role only. It is mandatory to have single sign-on enabled on the Data Fabric to be able to use the IAM policy feature.

An identity access management (IAM) policy is a security mechanism that states actions that can or cannot be performed by identities such as SSO users or groups on one or more resources that belong to one or more fabrics in a global namespace. An IAM policy defines allowable and disallowable actions on volumes, objects, and tables on more than one fabrics in a global namespace.

A fabric manager can create, modify, view, and delete IAM policies. A fabric manager can assign IAM policies to roles and vice-versa. A fabric manager can manage IAM policies from the Data Fabric UI, regardless of whether the fabric manager is logged on to the Data Fabric UI from the primary fabric or a non-primary fabric.

Use of IAM policies is recommended if you wish to associate a common set of allowable/disallowable actions on multiple disparate fabric resources at one go, that is, volumes, objects, tables in a global namespace for one or more SSO users and/or SSO groups.

TIP:

- Security policy can be configured exclusively for volumes belonging to a single fabric.
- Bucket policies can be applied exclusively to buckets on an object store from a fabric.
- A security policy or a bucket policy is associated with resources, while identity access management policy is associated with identities such as SSO users/groups and roles. As they apply to separate entities, security policies, bucket policies, and IAM policies can co-exist simultaneously.

About IAM Policy

Introduction to identity access management (IAM) policy.

An identity is an entity such as a user, a group or a role. A policy that defines the permissions on Data Fabric resources such as volumes, buckets, and database tables can be tagged to an identity.

An identity policy could apply to:

- one or more resources from multiple clusters
- multi modal resources (volumes/objects/tables)

All resources in a fabric must be represented with consistent naming scheme that is known as Unique Resource Name (URN) to uniquely locate/identify a specific resource.

As a fabric manager, you can create IAM policies by using the Data Fabric UI.

Identity Access Management Policy Life Cycle

Describes the life cycle of identity management policy.

An identity access management (IAM) policy goes through the following stages during its life cycle.

It is important to remember the following with respect to enforcement of an IAM policy:

- An IAM policy must be active and assigned to be enforceable on the SSO users and/or SSO groups, and roles. Similarly, an IAM policy must be inactive to be able to disarm the IAM policy.
- The time taken to enforce an IAM policy is anywhere between 2 and 30 minutes in a multi-cluster environment, depending on the number of identities involved in the operation.

Policy State	Policy State Description	Supported Transitions to other Policy States
Unassigned	Policy is yet to be assigned to an identity	Policy can be assigned, modified, or deleted
Assigned	Policy is assigned to an identity but not yet enforced	Policy can be unassigned from the current fabric resources to which it is assigned, modified, and deleted
Enforcing	Policy enforcement is in progress	The IAM policy cannot be assigned, unassigned, modified or deleted during the transient phase.
Enforced	Policy enforcement is complete	The IAM policy can be assigned, unassigned, modified, or deleted to other fabric resources.
Disarming	Policy deactivation is in progress	Policy cannot be assigned, unassigned, modified, or deleted.
Disarmed	Policy is deactivated	The IAM policy can be assigned, unassigned, modified, or deleted.

Resource-level Permissions in an IAM Policy

Describes various resource-level permissions that can be allowed or denied in an IAM policy.

You can configure the resource-level permissions at the following levels:

- Fabric level
- Bucket level
- Volume level

The following sections describe permissions at each of the aforementioned levels.

Fabric-level Permissions

You can configure the following permissions in an IAM policy for fabrics, external S3 servers, or external NFS servers.

Permission	Description
ViewClusterConfig	Permission to view cluster configuration.
ManageClusterServices	Permission to manage various fabric-level services.
ManageClusterOperations	Permission to manage cluster operations.
ManageClusterSettings	Permission to manage various cluster settings.
ManagemRoleOperations	Permission to manage operations related to user-defined roles.
ManageClusterACE	Permission to manage fabric ACE .
ManageStartStopService	Permission to start and stop fabric services
ManageClusterVolume	Permission to manage volumes on a fabric.

Volume-level Permissions

The following permissions can be granted in an IAM policy for volumes.

Permission	Description
ReadVolume	Permission to read a volume.
WriteVolume	Permission to write a volume.
DeleteVolume	Permission to delete a volume.
MountVolume	Permission to mount a volume.
MirrorVolume	Permission to mirror a volume.
ManageVolumeConfig	Permission to manage volume configuration.
ManageVolumeACE	Permission to manage volume ACE .
VolumeFullControl	Permission to perform all allowable operations on a volume.

Bucket-level Permissions

The following permissions can be granted in an IAM policy for Data Fabric S3 buckets.

Permission	Description
AbortMultiPartUpload	Permission to abort multi-part upload of an object to S3 bucket

Permission	Description
DeleteBucket	Permission to delete an S3 bucket
ForceDeleteBucket	Permission to force an S3 bucket deletion
DeleteBucketPolicy	Permission to delete an S3 bucket policy
DeleteObject	Permission to delete object from an S3 bucket
GetBucketLocation	Permission to get location or region for an S3 bucket
GetBucketNotification	Permission to get notification for an S3 bucket
GetBucketPolicy	Permission to get the policy of an S3 bucket.
GetObject	Permission to retrieve an object from S3 server/bucket.
HeadBucket	Permission to access S3 bucket to check for its existence and contents
ListAllMyBuckets	Permission to retrieve a list of S3 buckets owned by the sender of the request
ListBucket	Permission to retrieve a list of S3 buckets
ListBucketVersions	Permission to retrieve a list of S3 bucket versions
ListBucketMultiPartUploads	Permission to retrieve a list of the multi part uploads for an S3 bucket.
ListMultiPartUploadParts	Permission to retrieve list of parts in a multi-part upload into an S3 bucket
PutBucketLifeCycle	Permission to create a new lifecycle configuration for S3 bucket or replaces an existing lifecycle configuration.
GetBucketLifeCycle	Permission to retrieve lifecycle configuration for S3 bucket
PutBucketNotification	Permission to enable notifications for specified events related to S3 bucket.
PutBucketEncryption	Permission to configure encryption and keys on an S3 bucket
DeleteObjectTagging	Permission to delete object tagging
PutBucketPolicy	Permission to apply bucket policy to an S3 bucket
PutObject	Permission to add object to S3 bucket
PutObjectRetention	Permission to configure object retention settings on an object
GetObjectRetention	Permission to retrieve object retention configuration on an object
GetObjectLegalHold	Permission to retrieve the legal hold status for an object
PutObjectLegalHold	Permission to configure legal hold for an object.
GetBucketObjectLockConfiguration	Permission to retrieve the object lock configuration for an S3 bucket
PutBucketObjectLockConfiguration	Permission to configure the object lock settings for an S3 bucket
GetBucketTagging	Permission to retrieve the tags associated with an S3 bucket
PutBucketTagging	Permission to set tags for an S3 bucket
GetObjectVersion	Permission to access a specific version of an object
GetObjectVersionTagging	Permission to retrieve tag of an object version
DeleteObjectVersion	Permission to delete an object version
DeleteObjectVersionTagging	Permission to delete an object version tagging
PutObjectVersionTagging	Permission to set a tag for an object version
GetObjectTagging	Permission to retrieve the set of tags for an object
PutObjectTagging	Permission to set the tags for an object

Permission	Description
GetBucketEncryption	Permission to retrieve the encryption settings for an S3 bucket
PutBucketVersioning	Permission to set the versioning state for an S3 bucket
GetBucketVersioning	Permission to retrieve the versioning state for an S3 bucket
GetReplicationConfiguration	Permission to retrieve replication configuration
PutReplicationConfiguration	Permission to set replication configuration

Creating an IAM/Identity Policy

Describes the procedure to create an IAM/Identity policy.

Prerequisites

You must be a fabric manager to perform this operation.

About this task

You can create an IAM policy that comprises one or more statements for different resource types. Resources are of the following types:

- Fabric
- Volumes
- Buckets

For instance, you can allow a set of fabric-level permissions for multiple fabrics, including external S3 servers and/or external NFS servers by selecting the resource type as fabric for your statement. Another statement can be added for denial of various actions or operations related to specified buckets for the selected fabrics in the same policy.

An IAM policy is enforced when it is active and is attached or assigned to an identity like an SSO user, SSO group, and/or a user-defined role. The selected actions are allowed on the selected resources to the SSO users and/or SSO groups, when the policy is tagged/assigned to a user-defined role.

Follow the steps given below to create a IAM policy.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Security Administration icon > **Policy management** on the left pane.
3. Click the **Identity Policies** tab.
4. click **Create New**.
5. Enter the **Name** and **Description** for the IAM policy.
6. Turn the **Active** toggle off, if you wish to make the policy inactive. The **Active** toggle is on, by default.
7. Click **Manage Resources** and select the resource and the respective operations to allow or deny permissions on.
8. Click **Add** for **Statements** to add a statement to the policy.
9. Select the **Resource type** . Select fabric to add fabric-level permissions, volume to add permissions specific to volumes, or bucket to add permissions specific to buckets.

10. If you have chosen volume or bucket as the resource, select one or more Fabrics from the **Fabric** dropdown to which the volumes or buckets belong, and then click **Apply**.
11. Click **Add** for **Selected Resources**, select one or more fabrics or volumes or buckets, depending the resource type selected.
12. Select the resource-type specific actions that are to be allowed or denied on the selected resources.
13. Select the **Effect**. Select **Deny** to deny the selected actions on the selected resources. **Allow** is the default value.
14. Repeat steps 7 through 12 to add more statements, if required.
15. Click **Save**.

Results

An IAM/Identity policy is created. The newly created IAM/Identity policy is visible under the list of policies on the IAM policies card. The policy can be assigned to one or more identities such as SSO users, SSO groups, and/or user-defined roles.

Editing an Identity Policy

Describes the procedure to edit an identity policy

Prerequisites

You must be a fabric manager to perform this operation

About this task

You can edit an identity policy to add, change, or remove the assignment of the identity policy with users/groups/roles.

NOTE: Identity policy was known as IAM policy in some of the earlier Data Fabric versions.

You can also deactivate or activate an identity policy.

Follow the steps given below to edit a identity policy.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Security Administration icon > **Policy management** tab.
3. Click the **Identity policies** tab.
4. On the list of identity policies seen on the **Identity policies** tab, click the ellipsis under **Actions** for the identity policy to edit.
5. Click **Edit** to make changes to the identity policy.
6. Make the required changes to the various statements in the identity policy.
7. Click **Save**.

Results

The changes are saved to the identity policy and are reflected across the resources to which the identity policy has been assigned.

Viewing Identity Policy Details

Describes how to view the details for an existing identity policy.

Prerequisites

You must be a fabric manager to perform this operation.

About this task

Follow the steps given below to view all existing IAM policies.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Security Administration icon > **Policy management** tab.
3. Click the **Identity policies** tab.
4. On the list of identity policies seen on the **Identity policies** tab, click the ellipsis under **Actions** for the identity policy to view.
5. Click **View details** to view the details of the identity policies that have been defined.

Results

The details of the selected identity policy are displayed.

Assigning an Identity Policy

Describes how to assign an identity policy to an identity by using the Data Fabric UI.

Prerequisites

You must be a fabric manager to perform this operation.

About this task

When you assign an identity policy to one or more roles, SSO users, and/or SSO groups, the statements in the identity policy are applied to the role, SSO users, and/or SSO groups.

An identity policy is enforced when it is active and is attached or assigned to an identity like a user, group, and/or role. If an identity policy is inactive, it will not be disarmed, even if it is assigned to an identity.

NOTE: After assigning an identity policy, you can navigate out of the page using the breadcrumb on the top left side of the page.

Follow the steps given below to assign an identity policy.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Security Administration icon > **Policy management** tab.
3. Click the **Identity policies** tab.
4. On the list of identity policies seen on the **Identity policies** tab, click the ellipsis under **Actions** for the identity policy to assign.
5. Click **Assign Policy to** to assign the identity policy to another identity such as users/groups/roles.
6. Click **Add+** on the **Users** card, enter the search criteria and select the users that you wish to assign the identity policy to. This is an optional step.
7. Click **Add+** on the **Groups** card, enter the search criteria and select the groups that you wish to assign the identity policy to. This is an optional step.

8. Click **Add+** on the **Roles** card, enter the search criteria and select the roles that you wish to assign the identity policy to. This is an optional step.

Results

The policy is assigned to the selected SSO users, SSO groups, and/or roles. If the policy is active, it is enforced for the selected SSO users, SSO groups, and/or roles.

Deleting an Identity Policy

Describes how to delete an identity policy.

Prerequisites

You must be a fabric manager to perform this operation.

About this task

You can delete identity policies that are not assigned to any other identity type such as users/groups/roles. Follow the steps given below to delete a identity policy.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Security Administration icon > **Policy management** tab.
3. Click the **Identity policies** tab.
4. On the list of identity policies seen on the **Identity policies** tab, click the ellipsis under **Actions** for the identity policy to delete.
5. Click **Delete** and type DELETE in the provided text area to confirm deletion.

Results

The identity policy is deleted.

Configuring Email Notifications

Describes how to configure the Simple Mail Transfer Protocol (SMTP) to send email notifications from the Data Fabric UI to specified email accounts.

The Data Fabric UI can notify you by email when alarms are generated on a fabric. To configure email notifications, you must set up SMTP:

Setting Up SMTP

To set up SMTP:

1. Sign in to the Data Fabric UI, and switch to the **Fabric manager experience**.
2. Click the Fabric administration icon on the left pane.
3. Click the **Others** tab and scroll down to the **SMTP** card.
4. On the **SMTP** card, click **Edit SMTP settings**. The **Edit SMTP settings** form is displayed.
5. Specify the following parameters:

Parameter	Description	Example
Provider*	Select Office 365 , SMTP , or Other from the drop-down menu. If you select Office 365 , the SMTP server and port information is pre-filled for you.  NOTE: Gmail is provided as an option, but is not currently supported because Gmail does not support unsecure emails from third-party applications. For more information, see this page .	Office 365
SMTP server*	The name of the mail server for the SMTP provider that you specified.	smtp.office365.com
This server requires an encrypted connection (SSL)	Check this box if the connection to the SMTP server must be encrypted.	N/A
SMTP port*	The SMTP port to use for sending mail.	587
Sender's full name*	The name that the HPE Data Fabric should use when sending email.	East Lab Data Fabric
Sender's email address*	The email address that the HPE Data Fabric should use when sending email.	jennifer-huang87@outlook.com
Sender's username	(Optional) The user name that the HPE Data Fabric should use when logging on to the SMTP server.	jennifer46
Sender's SMTP password	(Optional) The password that the HPE Data Fabric should use when logging on to the SMTP server.	mySMTP!pw

6. Click **Save**. A message indicates if the configuration was successful.

7. See [Setting Up Alarm Notifications](#) on page 1169.

Editing SMTP Settings

After SMTP has been configured, you can edit the settings by clicking **Edit SMTP settings**, changing the parameter values as needed, and clicking **Save**.

Setting Up Alarm Notifications

Setting up SMTP does not by itself enable alarm notifications. You must also identify the alarms for which you want to be notified. Currently, setting up alarms must be done using the `maprc li` command line. You must run the `config save` command for each alarm where you want to generate an email.

 **WARNING:** You must have `fc` (full control) or `a` (admin) permissions to run this command.

The format of the command is:

```
maprc li alarm config save -cluster <fabric_name> -values
"<alarm>,<enableEmail>,<email>"
```

Assign values as follows:

Value	Description	Example
alarm	Name of the alarm. Specify the alarm name in uppercase with underscores. For a list of Data Fabric alarms, see Alarms Reference .	DISK_FAILURE_ALARM

Value	Description	Example
enableEmail	Specifies whether individual alarm notifications are sent to any email address (including the default email address) for the alarm type: <ul style="list-style-type: none"> 0 – Do not send notifications to any email address for the alarm type. 1 – Send notifications to all email addresses for the alarm type. 	1
email	One or more email addresses other than the default email address. If specified, alarm notifications are sent to these addresses as well, if enableEmail is set to 1. Multiple email addresses must be separated by spaces only. You cannot use commas or other delimiters. For example, user1@mycorp.com user2@mycorp.com is valid.	jennifer-huang87@outlook.com

Example

The following example command configures an email to be sent to test@example.com whenever the **Node Alarm Core Present** alarm is generated:

```
maprcli alarm config save -values
"NODE_ALARM_CORE_PRESENT,1,test@example.com"
```

View alarms on the [Data Fabric UI](#) on page 1100.

Viewing and Editing Access Control Information

Describes how to find and use the Access Control card that shows the access privileges for users and groups.

Note the following prerequisites for viewing and changing access control information:

- You must have fabric manager permissions to view or change access control settings.
- The user or group for which you want to assign access must already be configured for the fabric.

Viewing the Access Control Card

To view the **Access control** card:

1. Sign in to the Data Fabric UI, and switch to the **Fabric manager** view.
2. Click the Fabric administration icon on the left pane.
3. View the **Manage access** card on the **Manage access** tab.

Changing Access Control Settings

To add or change the access control information for a user or group:

1. On the **Manage access** card, click **Edit access**. The Data Fabric UI displays the current settings.
2. Refer to the following table to change access settings for a user or group:

To	Do this
Add a new user or group	Click +Add , specify the Type (User or Group), and select the desired access options.

To	Do this
Change the access for an existing user or group	Select or deselect the the desired access options.
Remove a user or group	Click the garbage can icon ().

3. Click **Save** to save your changes, or click **Close** to exit without saving changes.

Administering Buckets

Describes the operations you can perform related to buckets for the HPE Data Fabric.

Buckets are storage resources that store objects, which consist of data and its descriptive metadata.

Object-based storage is the preferred method of storing and efficiently managing gigantic volumes of data. Data are stored efficiently in a flat address space called as a storage pool and not as a tiered file structure. The address space is referenced by the metadata that holds the required information to retrieve the data. The metadata facilitates deep analysis of the usage and function of the data that is stored in the storage pool. The access protocol used in object storage architecture is TCP/IP and the communication medium is usually through REST APIs.

Objects can comprise disparate types of unstructured data such as audio files, video files, and images.

A user can store objects in the user's own account. Objects are stored inside containers called buckets. Every user can create buckets and set access policies or bucket policies to govern who can access the resources created by the user.

See [Administering Bucket Policies](#) on page 1249 for information on managing bucket policies.

Creating a Bucket

Create a bucket on a fabric.

Prerequisites

- A fabric must be available for you to create a bucket.
- You must have permissions to create a bucket on the fabric.

About this task

Buckets can be created on a fabric that exists on a public cloud provider.

When you create a bucket, you must ensure that the bucket name is

- globally unique for your fabric
- starts and ends with a lowercase letter or a number
- between 3 and 63 characters long
- contains characters in lowercase only

You can enable locking of objects that are stored on the bucket. Object locking is useful when you wish to prevent overwriting of objects for a specific time duration. When you lock an object, multiple versions of the object can be stored. Each object version is unalterable. Once object locking is enabled on an object, you cannot disable it for the object. You can specify the retention mode and retention period.

If you wish to create a versioned bucket to store multiple object versions with an object lock, you must select the **Enable Object Lock** check box. The **Object versioning** check box is auto-selected when you enable object locking.

You can create a bucket to store multiple object versions without enabling an object lock. In this case, you must select the **Object versioning** check box and leave the **Enable Object Lock** check box deselected.

You can select the erasure coding type while creating a bucket. Select **Instant Tiering** for storage or space efficiency. Select **Scheduled Tiering** for performance efficiency. Select **System Default** to apply the system-wide configuration.

Follow the steps given below to create a bucket.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. Click **Actions > Create bucket**.
5. Enter the **Name**.
6. Select the **Resource type** on which you wish to create the bucket. Select **Fabric** to create a bucket on a fabric. Alternatively, select **External S3** to create a bucket on an external S3 server.
7. If you have selected resource type as **Fabric**, and then select the fabric on which the bucket is to be created. If you have selected the resource type as **External S3**, select the external S3 server on which the bucket is to be created.
8. Enter the **Account name** that owns the bucket.
9. Select the **Enable Object Lock** check box to enable object versioning and prevent deletion of objects. This is an optional step.
10. Select the **Object versioning** check box if you wish to enable object versioning, but do not wish to disable deletion of objects. This is an optional step.
11. Select the **Erasure coding type**.
12. Click **Create**.

Results

The bucket is created on the fabric.

You can now upload objects to the bucket. You can create one or more folders on the bucket to store objects. The selected erasure coding mechanism is applied to the bucket.

Related maprcli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprcli` command. The command is provided for general reference. For more information, see [maprcli Commands in This Guide](#).

- `mc mb`

Creating a Folder on a Bucket

Create a folder on a bucket to store objects.

About this task

You can create folders on a bucket to segregate the objects to store on the bucket.

You can create subfolders inside folders.

Follow the steps given below to create a folder on a bucket.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the bucket on which you wish to create a folder.
5. Click the bucket name seen under **Resource Name**.
6. Click **Create Folder** on the **Objects** tab.

NOTE: If you are creating a sub-folder, you must navigate into the folder where you wish to create the sub-folder, and then click **Create Folder**.

7. Enter the **Folder name**.
8. Click **Create**.

Results

The folder is created in the bucket. You can store objects in the folder.

Uploading Objects to a Bucket

Upload one or more objects to a bucket.

Prerequisites

- Your account must have the permission to upload object on the bucket.
- The bucket to which you wish to upload object must have enough space to store the object.

About this task

You can upload one or more objects of size upto 1 GB to a bucket.

If object versioning is enabled on the bucket, you can store multiple files with the same name on the bucket.

Follow the steps given below to upload objects to a bucket.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the bucket to which you wish to upload objects (files).
5. Click the bucket name seen under **Resource Name**.
6. Click **Upload Objects** on the **Objects** tab.
7. Click **browse** to select one or more files to upload. Alternatively, drag and drop one or more files to **Upload files** area.

8. If you wish to store the files to upload as versions of the same object, enter the **Destination file name**. The files are stored as multiple versions of the same object in this case.

9. Click **Upload**.

Results

The selected files are successfully uploaded to the object store and appended to the list of objects for the fabric seen on the Data Fabric UI.

If you have uploaded multiple files with the same name, that is, if you have uploaded multiple versions of an object, the multiple files are seen having the same file name with a version number in parentheses.

Downloading an Object from a Bucket

Download an object from a bucket.

Prerequisites

- You must have the permission to download an object from a bucket.

About this task

You can download one or more objects that are stored on a bucket. You can download only one object at a time.

Follow the steps given below to download an object from the bucket.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the bucket from which you wish to download the object(file).
5. Click the bucket name seen under **Resource Name**.
6. Click the ellipsis seen under **Actions** for the object row to download on the **Objects** tab.
7. Click the **Download** option.

Results

The object is downloaded to the default download folder on your machine or to the folder that you select. The destination folder for the object depends on your web browser settings.

Deleting an Object from a Bucket

Delete an object from a bucket.

Prerequisites

- You must have the permission to delete an object from a bucket.

About this task

You can delete versioned and unversioned objects from a bucket.

When you delete a versioned object, the object is merely marked for deletion and not actually deleted from the bucket.

When you delete an unversioned object, the object is permanently removed from the bucket.

Follow the steps given below to delete objects from a bucket.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the bucket from which you wish to delete objects (files).
5. Click the bucket name seen under **Resource Name**.
6. Click the ellipsis seen under **Actions** for the object row to delete on **Objects** tab.
7. Click the **Delete** option.
8. Click **Delete** on the message box that appears.

Results

If the object is unversioned, the object is permanently removed from the bucket. If the object is versioned, it is marked for deletion.

Related maprcli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprcli` command. The command is provided for general reference. For more information, see [maprcli Commands in This Guide](#).

- `mc rm`

NOTE: You might not be able to delete an object from GCP by using the minio client (mc). You would need to use the AWS CLI to do so. This is a known minio client issue. For more information about the issue, see <https://issuetracker.google.com/issues/162653700>.

Deleting a Folder from a Bucket

Delete a folder from bucket.

Prerequisites

- The folder to delete must not contain objects.
- You must have the permission to delete a folder from a bucket.

About this task

You can delete a folder from a bucket when the folder does not contain any objects.

Follow the steps given below to delete a folder from a bucket.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.

4. In the tabular list of fabrics, click the down arrow for the fabric that contains the bucket from which you wish to delete a folder
5. Click the bucket name seen under **Resource Name**.
6. Click the ellipsis seen under **Actions** for the folder row to delete on **Objects** tab.
7. Click the **Delete** option.
8. Click **Delete** on the message box that appears.

Results

The folder is deleted from the bucket.

Deleting a Bucket

Delete a bucket from fabric.

Prerequisites

- The bucket to delete must be empty.
- You must have the permission to delete a bucket.

About this task

You can delete a bucket from a fabric.

Follow the steps given below to delete objects from a bucket.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. Click the Table View icon on the **Resources** card. In the tabular list of fabrics, click the down arrow for the fabric that contains the bucket that you wish to delete.
5. Locate the row for the bucket to delete in the Resources seen under the fabric.
6. Click the ellipsis seen under the **Actions** column for the bucket row.
7. Click the **Delete** option.
8. Click **Delete** on the message box that appears.

Results

The bucket is deleted from the fabric.

Related maprccli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprccli` command. The command is provided for general reference. For more information, see [maprccli Commands in This Guide](#).

- `mc rb`

Creating Object Lifecycle Rules on Bucket

On the Data Fabric UI, create lifecycle rules on buckets for the non-versioned and versioned objects contained in a bucket. The object lifecycle rules can be configured on a bucket.

About this task

You can configure one or more object lifecycle rules on buckets. Once the object lifecycle rules are configured on a bucket, the rules apply to all the current and future objects contained in the bucket. See [Object Lifecycle](#) on page 624 for an introduction to the object lifecycle.

Object lifecycle rules can have filters based on object name prefix, tags, and object size. You can configure more than one conditions for the action to be taken.

Use one or more filter types for objects, depending on what filter you wish to set for the lifecycle rule to apply.

For example, if you wish to delete objects starting with 'one' and minimum object size as 10 MB, enter prefix as 'one', and minimum object size as 10 MB.

The following table specifies the suffix to use for the required unit of measurement for object size.

Table

Unit of measurement
KB (Kilobytes)
MB (Megabytes)
GB (Gigabytes)
TB (Terabytes)
PB (Petabytes)
EB (Exabytes)
ZB (Zettabytes)

NOTE: Uncommitted multipart upload rules do not support tags or object size filters as they are incomplete transactions for which the tags and sizes are updated only on completion.

Follow the steps given below to create an object lifecycle rule by using the Data Fabric UI:

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the bucket on which you wish to configure object life cycle rule or rules.
5. Click the bucket name seen under **Resource Name**.
6. Click the **Management** tab.
7. Click **Create Lifecycle rule**.
8. Enter the **Lifecycle rule name**.
9. To create a rule that is applicable to a selected set of objects that meet one or more conditions, select the **Limit the scope of this rule using one or more filters** option. To create a rule that is applicable to all objects in the bucket, select the **Apply to all objects in the bucket** option.

10. If you wish to create a rule for a specific set of objects, enter the prefix, one or more key-value pairs for object tags, the minimum object size and/or the maximum object size, along with the unit of measurement. Use one or more filter types for objects, depending on what filter you wish to set for the lifecycle rule to apply.
11. Click **Next**.
12. Select the Actions for the objects in the bucket. If you wish to expire the current version of objects after a specified number of days, select the **Expire current versions of objects** check box, and enter the number of **Days after object creation** after which to expire the object. If you wish to permanently delete non-current versions of objects, select the **Permanently delete noncurrent versions of objects** check box, enter the number of **Days after which objects become noncurrent** and **Number of newer versions to retain**.
13. Click **Next** to review the rule.
14. Click **Create lifecycle rule** to create the object lifecycle rule. The lifecycle rule is enabled on creation. The object lifecycle rule is created. The rule is visible under the list of lifecycle rules under the **Management** tab.

Editing Object Lifecycle Rule

On the Data Fabric UI, edit an existing object lifecycle rule that has been created for non-versioned and versioned objects contained in a bucket.

About this task

Follow the steps given below to edit an object lifecycle rule by using the Data Fabric UI:

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the bucket on which you wish to configure object life cycle rule or rules.
5. Click the bucket name seen under **Resource Name**.
6. Click the **Management** tab.
7. For the object lifecycle rule to edit, click the ellipsis () in the **Actions** column, and then click **Edit**.
8. Make the required changes and click **Update lifecycle rule**.

Results

The changes are saved to the lifecycle rule.

Enabling Object Lifecycle Rule

On the Data Fabric UI, enable an existing object lifecycle rule that has been created for non-versioned and versioned objects contained in a bucket.

Prerequisites

The object lifecycle rule to enable must be in the disabled state.

About this task

Follow the steps given below to enable a disabled object lifecycle rule by using the Data Fabric UI.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the bucket on which you wish to configure object life cycle rule or rules.
5. Click the bucket name seen under **Resource Name**.
6. Click the **Management** tab.
7. For the object lifecycle rule to edit, click the ellipsis () in the **Actions** column, and then click **Enable**.

Results

The object lifecycle rule is enabled.

Deleting Object Lifecycle Rule

On the Data Fabric UI, delete an existing object lifecycle rule that has been created for non-versioned and versioned objects contained in a bucket.

About this task

You can delete one object lifecycle rule at a time.

Follow the steps given below to delete an object lifecycle rule by using the Data Fabric UI.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the bucket on which you wish to configure object life cycle rule or rules.
5. Click the bucket name seen under **Resource Name**.
6. Click the **Management** tab.
7. For the object lifecycle rule to edit, click the ellipsis () in the **Actions** column, and then click **Delete**.
8. Confirm the deletion by clicking **Delete** on the confirmation message.

Results

The object lifecycle rule is deleted.

Disabling Object Lifecycle Rule

Prerequisites

The object lifecycle rule to disable must be in the enabled state.

About this task

Follow the steps given below to disable an enabled object lifecycle rule by using the Data Fabric UI.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the bucket on which you wish to configure object life cycle rule or rules.
5. Click the bucket name seen under **Resource Name**.
6. Click the **Management** tab.
7. For the object lifecycle rule to disable, click the ellipsis () in the **Actions** column, and then click **Disable**.

Results

The object lifecycle rule is disabled.

Administering Tables

Describes the operations you can perform related to tables for HPE Data Fabric.

Tables on HPE Data Fabric provide a native implementation of the HBase Table for improved scalability, stability, and speed on the Data Fabric platform.

With HPE Data Fabric tables, you can:

- Create and access tables in the Data Fabric UI.
- Access tables with a global path.
- List and filter tables.
- Create and manage access controls through the Data Fabric UI.
- Enable read optimization to improve the speed of large read workloads.

Creating a Table

This topic describes creating a table.

Prerequisites

- A fabric must be available for you to create a table.
- You must have the permissions to create a table on the fabric.

About this task

Follow the steps given below to create a table.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. Click **Actions > Create Table**.
The **Create Table** side drawer opens.
5. Enter the table **Name**.
6. The table **Path** field is automatically filled. However, you can edit the **Path** if desired.
The table is automatically assigned a fabric-specific full path, which you can use to access the table from the global namespace.
7. Select the name of the **Fabric** on which you want to create the table from the dropdown menu.
8. Enter a **Column family name** for your table. During the table creation process, you can create only one column family.
9. Click **Create**.

Results

The table is created on the fabric.

After successful table creation, you can add additional column families to the table, as described in [Creating a Column Family](#) on page 1183.

Viewing the List of Tables

View the list of tables created on a fabric.

About this task

Use the following steps to view tables created on a fabric.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. , click the **Graph View** icon on the **Resources** card.
The **Graph View** opens:

- To open the tabular list of tables, hover over the **tables** card in **Graph View** and click **View in table**. Alternatively, under the default **Fabric user experience**, click the **Table View** icon on the **Resources** card.

The **Table View** opens:

Resource Name	Type	Provider	Size	Owner	Action
ez-df-cluster	Fabric	OnPrem	0 % 3 Gb of 207 GB	admin	
/data/monthly	Table	—	1.08 GiB	admin	
/data/quarterly	Table	—	0.11 GiB	admin	
/ezmera...s/accounts	Table	—	0.00 GiB	admin	
data	Volume	—	1.17 GiB	admin	

- To view information about a specific table, click the name of the table in **Table View**.

Deleting a Table

This topic describes deleting a table.

Prerequisites

- You must have the permissions to delete tables on the fabric.

About this task

Follow the steps given below to delete a table.

Procedure

- Log on to the Data Fabric UI.
- Click the All resources icon on the left pane, click the table view icon.
- Select the **Resource details** check box.
- Click the **Table View** icon.
- Click the ellipsis () in the **Action** column of the table you want to delete.

6. Click **Delete**.

Results

The table is deleted from the fabric.

Creating a Column Family

This topic describes creating a column family.

Prerequisites

- A table must be available for you to create a column family.
- You must have the permissions to create column families on the table.

About this task

Follow the steps given below to create a column family on a table.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the table on which you want to create a column family.
5. Click the table name seen under **Resource Name**.
6. Click **Add column family** on the **Column families** tab.
The **Add column family** wizard opens on the **Column family details** screen.
7. Enter the **Column family name**.
8. Enter the **Max version** and **Min version** for your column family. This is the the maximum and minimum number of versions that are retained upon revision to the column family.
9. Click the toggle to enable **Read optimization**. Read optimization enables in-memory caching for read workloads, greatly improving the speed of read operation for large workloads.
10. **(Optional)** Create user access controls for your column family.
The wizard automatically creates a default column family **Access control** entry. You can edit the default entry, or delete it with the action button (trash can).
 - a) Select the user **Type**.
 - b) Enter the user **Name**.
 - c) Select the permissions you want the user to have:
 - **Read**: The user has read permissions on the column family.
 - **Write**: The user has write permissions on the column family.
 - **Append**: The user has append permissions on the column family.
 - **Version**: The user can roll the column family back to a previous version.
 - d) **(Optional)** Click **Add** to create another user access control for the column family.

11. Click **Manage column permissions.**

The **Add column family** wizard opens the **Manage column permissions** window. From this window, you can create columns and column-specific access controls.

12. (Optional) To create a column in the column family, enter the column name.**13. (Optional) Create user access controls for your column.**

The wizard automatically creates a default column **Access control** entry. You can edit the default entry, or delete it with the action button (trash can).

- a) Select the user **Type**.
- b) Enter the user **Name**.
- c) Select the permissions you want the user to have:
 - **Read**: The user can read the entries in the column.
 - **Write**: The user can alter the existing column entries.
 - **Append**: The user can add new records to the column.
- d) **(Optional)** Click **Add** to create another user column in the column family.

14. Click **Apply.****Results**

The column family is created on the table with the defined access controls and columns.

Viewing Column Families

View column families created on a table.

About this task

You can view column families from the Data Fabric UI.

Use the following steps to view column families.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the table.
5. Click the name of the table for which you want to view column families.
The table **Overview** screen opens.
6. Click the **Column families** tab.

Results

You can now view the list of column families.

Configuring Column Family Permissions

This topic describes configuring column family permissions for a table.

Prerequisites

- A table with a column family must be available for you to configure column family permissions.

- You must have the permissions to configure column families on the table.

About this task

Follow the steps given below to create or edit column family permissions on a table.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the table on which you want to create or edit column family permissions.
5. Click the table name seen under **Resource Name**.
The **Table details** view opens.
6. Select the **Column families** tab. On this tab, you can view all column families created on the table.
7. Perform one of the following:
 - Click the ellipsis () in the **Action** column of the column family for which you want to create or edit column family permissions.
 - Click the name of the column family for which you want to create or edit column family permissions.
The **Column family details** view opens. Then, click the ellipsis ().
8. Click **Edit**.
The column family wizard opens.
9. Click **Manage column permissions**.
The column family wizard opens the **Manage column permissions** window. From this window, you can create columns and column-specific user access controls.
10. Enter the column name.
11. Define user access controls for your column.
The wizard automatically creates a default column **Access control** entry. You can edit the default entry, or delete it with the action button (trash can).
 - a) Select the user **Type**.
 - b) Enter the user **Name**.
 - c) Select the permissions you want the user to have:
 - **Read**: The user has read permissions on the column.
 - **Write**: The user has write permissions on the column.
 - **Append**: The user has append permissions on the column.
 - d) **(Optional)** Click **Add** to create another user access control for the column.
12. **(Optional)** Click **Add column permissions** to define user access controls for another column.

13. Click **Apply.****Results**

The permissions are applied to the column family with the defined user access controls on the columns.

Deleting a Column Family

This topic describes deleting a column family.

Prerequisites

- You must have the permissions to delete column families from the table.

About this task

Follow the steps given below to delete a column family from a table.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the table on which you want to delete a column family.
5. Click the table name seen under **Resource Name**.
6. Select the **Column families** tab.
7. Click the ellipsis () in the **Action** column of the column family you want to delete.
8. Click **Delete**.

Results

The column family is deleted from the table.

Managing Table Replication

The topics in this section describe managing table replication.

You can use table replication to improve data availability and load balancing.

- **Availability:** Replicate tables between different fabrics within your cluster.
- **Load balancing:** Use table replicas to reduce the load on the primary table. For example, you can run data analysis tasks on a replica of the primary table rather than the primary table itself.

Adding a Table Replica

This topic describes adding a table replica.

Prerequisites

- A table must be available for you to create a replica.
- You must have the permissions to create table replicas.

About this task

Follow the steps given below to create a table replica.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the table for which you want to create a replica.
5. Click the table name seen under **Resource Name**.
6. Click **Add replica** on the **Replication** tab.
7. The wizard automatically fills the name of the **Source fabric** and **Path to source table**.
8. Select the **Destination fabric** from the dropdown menu.
9. Enter the **Replica path**.
10. **(Optional)**: Click the toggle to enable **Advanced options**:
 - **Throttle**: Enable throttling to limit the speed of connection. Use this option to minimize the impact on the primary table, especially when under heavy load.
 - **Synchronous**: Enable synchronous replication.
 - **Encrypt on wire**: Enable this option to encrypt the replicated data during transfer.
11. Click **Column families**.
The **Add replica** wizard opens the **Column families** window.
12. Select the column families you want to replicate.
You can either:
 - **Replicate all column families**.
 - **Replicate specific column families**:
 - a. Click the toggle for the column families you want to replicate.
 - b. For each column family, you can either replicate **All columns** in the column family or you can **Assign columns** to replicate.
 - c. If you select **Assign columns**, enter the column name in the **Column name** field. Click **Add** to add another column to replicate.
13. Click **Add**.

Results

The table replica is created in the specified location.

Viewing Table Replicas

View the list of created table replicas.

Prerequisites

You must have permission to view table replicas.

About this task

You can view table replicas from the Data Fabric UI.

Use the following steps to view table replicas.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the table replica.
5. Click the name of the table for which you want to view replicas
The table **Overview** screen opens.
6. Click the **Replication** tab.

Results

You can now view the list of table replicas.

Administering Access Controls for Tables

This topic describes administering access controls for tables.

Prerequisites

- To add or edit user access controls, you must have Admin permissions on the table.

About this task

Follow the steps given below to create user access controls for a table.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the table for which you want to manage access controls.
5. Click the name of the table for which you want to manage access controls.
The table **Overview** screen opens.
6. Click the **Settings** tab.
7. Click the **Access Control** button.
The **Access Control** wizard opens.
8. Select the user type for the access control.
9. Enter the user name.
10. Select the permissions you want the user to have:
 - **Admin (Access control)**: The user can create, edit, and delete access controls for the table.

- **Create/rename column family**
- **Delete column family**

11. (Optional) Click **Add** to create another access control for the table.

12. Click **Save**.

Administering Topics

Administer topics for Apache Kafka Wire Protocol with HPE Data Fabric.

Data Fabric supports creation of topics for Apache Kafka Wire Protocol via the Data Fabric UI.

A topic is given a unique name that is used to categorize and organize messages based on common properties.

One or more producers publish messages to topics. Individual consumers subscribe to the topics of their choice to consume the messages that are published to such topics.

For example, a producer could be publishing weather-related data such as daily rainfall to a topic called dailyrain. A consumer could be subscribing to the topic containing the daily rainfall.

Creating a Topic

Create a topic for Apache Kafka Wire Protocol.

Prerequisites

- Topic with the name must not already exist on the fabric.
- You must be a fabric user to create a topic on the fabric.

About this task

One or more topics for Apache Kafka Wire Protocol can be created on a fabric, via the Data Fabric UI.

Data is stored in topics in the form of messages for the retention period specified while creating the topic. The retention period can be specified in seconds, minutes, hours, or days. The default unit for retention period is days.

Data can be stored in uncompressed and compressed formats in topics. By default, data on topics is uncompressed.

Data compression helps reduce network bandwidth usage and saves disk space. Data compression results in higher CPU utilization.

Data Fabric supports the following algorithms to compress data in a topic.

- LZ4 - LZ4 is an extremely fast /high-speed lossless compression algorithm.
- LZ4F – java-based compression algorithm that is optimized for speed with modest data compression
- ZLib – Zlib is an open-source mechanism to provide for lossless compression.

If you wish to store data in a compressed format on the topic, you can select the compression algorithm based on your environment and requirement.

Follow the steps given below to create a topic.

Procedure

- 1.** Log on to the Data Fabric UI.
- 2.** Click the All resources icon on the left pane, click the table view icon.

3. Select the **Resource details** check box.
4. Click **Actions > Create topic**.
5. Enter the topic name.
6. Select the fabric on which you wish to create the topic.
7. Enter the number of partitions for the topic
8. Enter time to live for the topic. This is the duration for which messages are retained within the topic.
9. Choose the compression type.
10. Click **Create**.

Results

The topic is created on the specified fabric. A message regarding the topic creation is displayed on the Data Fabric UI.

Related maprcli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprcli` command. The command is provided for general reference. For more information, see [maprcli Commands in This Guide](#).

- `stream topic create`

Editing a Topic

Edit a topic for Apache Kafka Wire Protocol.

Prerequisites

- Topic to edit must exist.
- You must have permission to edit a topic.

About this task

You can edit a topic for Apache Kafka Wire Protocol via the Data Fabric UI.

The following fields related to a topic are editable.

- Number of partitions
- Time to live
- Compression scheme

Follow the steps given below to edit a topic.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the topic to edit.
5. Click the topic name seen under **Resource Name**.

6. Edit the topic as required.
7. Click **Save**.

Results

The changes made to the topic are saved. A message regarding the successful modification is displayed on the Data Fabric UI.

Related `maprccli` Commands

Viewing or Downloading Topic Connection Properties

View and download connection properties related a topic for Apache Kafka Wire Protocol.

Prerequisites

You must be a fabric user or a fabric manager to view and download connection properties for topic.

About this task

You can view and/or download topic connection properties from the Data Fabric UI.

Use the following steps to view or download connection properties.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the topic.
5. Click the **View Connection Properties** in the **Endpoint** column for the topic, to view the connection properties.
6. If you want to download the connection properties, click **Download** on the **Connection Properties** dialog box.

Results

The connection properties file is downloaded to the default downloads folder on the local machine.

Deleting a Topic

Delete a topic for Apache Kafka Wire Protocol.

Prerequisites

- The topic to delete must exist.
- You must be a fabric user to delete a topic.

About this task

You can delete a topic associated with a fabric.

Follow the steps given below to delete a topic.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the topic to delete.
5. Click the topic name seen under **Resource Name**.
6. Locate the topic to delete.
7. Click the ellipsis under **Actions** for the topic row in the tabular list of resources.
8. Click the **Delete** menu option.
9. Click **Delete** to confirm topic deletion.

Results

The topic is permanently deleted, along with the data stored on the topic. A message regarding the topic deletion is displayed on the Data Fabric UI.

Related maprcli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprcli` command. The command is provided for general reference. For more information, see [maprcli Commands in This Guide](#).

- `stream topic delete`

Administering Volumes

Administer volumes on HPE Data Fabric.

HPE Data Fabric provides volumes as a way to organize data and manage fabric performance.

A volume is a logical storage unit that allows you to apply policies to a set of files, directories, and sub-volumes. You can use volumes to enforce disk usage limits, establish ownership and accountability, and measure the cost generated by different projects or departments. For example, you could create a volume for each user, department, or project.

A volume consumes storage space only when data is written to the volume.

Volume Types

Volumes can be of the following types.

- **Standard volume:** A initial or original volume that contains data.
- **Mirror volume:** A replica of a standard volume that replicates the data present on a standard volume.

Volume Data Backup

Following are the ways in which data on volumes can be backed up for restoration purpose.

- **Creating mirrors or mirror volumes:** Data in a volume is replicated when you create mirror volumes. A volume that is mirrored is called a standard volume. The mirrored version of a volume is called a mirror volume. You can create mirrors of mirror volumes to replicate the data present on mirror volumes. Such volumes are called cascading mirrors.

- **Creating volume snapshots:** The state of data in a volume is recorded at the point-in-time of the volume snapshot creation. A snapshot is a read-only image of a volume at a specific point in time. Snapshots are useful any time you need to be able to roll back to a known good data set at a specific point in time. For example, before performing a risky operation on a volume, you can create a snapshot to enable rollback capability for the entire volume.

A snapshot takes no time to create, and initially uses no disk space, because it stores only the incremental changes needed to roll the volume back to the state at the time the snapshot was created. The storage used by a volume's snapshots does not count against the volume's quota.

Security policies can be applied to volumes to control access to the volume data. See [Administering Security Policies](#) on page 1229 for more information.

Creating a Standard Volume

Procedure to create standard volume.

Prerequisites

- The fabric for which you wish to create the volume must have been created on the cloud or on-premises, or in an air-gapped environment.
- You must have the permission to create a volume.
- If you wish to enable data at rest encryption for the volume, the fabric must have data-at-rest encryption enabled.
- If you wish to associate a security policy with the volume, the security policy must have been created by the fabric. manager.

About this task

The task describes how to add standard volume via the Data Fabric UI.

A standard volumes is a volume where data is originally written. A standard volume is read-write, default. It can marked as read-only, if required.

You have the option to create a new storage policy or create a new remote target to cold tiering of the volume. You can create a new storage policy or a remote target if you have not already created one or wish to create a new storage policy or remote target for the cold data that would be stored on the volume to create.

Follow the steps given below to create a standard volume.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the Resource details check box.
4. Click **Actions > Create Volume**.
5. Enter the volume name.
6. Select the fabric on which you wish to create the volume.
7. Select the Standard option for **Type**.
8. Specify the **Mount Path** for the volume.

9. Enter the **Volume Limit**. The value specified for the volume limit must be less than or equal to the fabric capacity.
10. Select a security policy for the volume. This is an optional step.
11. Turn on the **Data at rest encryption** toggle to enable encryption for data at rest. This is an optional step.
12. Turn on the Data tiering toggle to enable data tiering to be able to offload data to cold tier. This is an optional step.
 - a) If you enable data tiering, select tiering type. On selecting tiering type as **Remote archiving(Cold)**, you can offload data to a cold tier.
 - b) If you have selected **Remote archiving (cold)**, select the **Storage policy** and the **Remote Target**. You can create a new storage policy and/or a remote target by clicking Create new under the respective dropdowns.
13. Click **Create**.

Results

The volume is successfully created on the selected fabric and the details are displayed in the list of resources under the respective fabric on the **Resourcecard**.

If you have turned on data tiering, tiering is enabled on the volume and you can configure tiering options on the **Settings** tab for the volume.

Related maprccli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprccli` command. The command is provided for general reference. For more information, see [maprccli Commands in This Guide](#).

- `volume create`

Creating a Mirror Volume

Procedure to create mirror volume.

Prerequisites

- The fabric for which you wish to create the volume must have been created on the cloud or on-premises or in an air-gapped environment.
- The standard volume that you wish to mirror must have been created, before you can create a mirror volume.
- You must have the permission and valid activation key to create a mirror volume on the fabric.

About this task

A mirror is a replica of a standard volume and consumes space on the disk. You can create a mirror of an existing volume by using the Data Fabric UI.

Mirror volumes can be used for data recovery to recover data on corrupted or lost volume data.

A mirror volume can be created on-premise or in the cloud, based on your fabric setup. Mirror volumes can be created on a fabric other than the fabric to which the source volume belongs.

Mirror volumes created on-premise are called local mirrors.

Mirror volumes can be local or remote.

Remote mirrors are used for disaster recovery, while local mirrors are used for load balancing.

Mirror volumes that are created from mirror volumes are called cascading mirrors.

Follow the steps given below to create a mirror volume.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the fabric containing the volume to mirror.
5. Click the ellipsis under **Actions** for the volume to mirror, on the list of resources, and click the **Create mirror** option to create a mirror for the volume.
6. Enter the volume name.
7. Select the fabric on which you wish to create the volume from **Source Fabric**.
8. Select the Mirror option for **Type**.
9. Select the **Source Cluster** that represents the cluster/fabric that contains the volume to replicate.
10. Select the **Source Volume** to replicate. This is non-editable if you have already chosen the volume to mirror.
11. Specify the **Mount Path** for the volume.
12. Enter the **Volume Limit**. The value specified for the volume limit must be less than or equal to the fabric capacity.
- 13.
14. Select a security policy for the volume. This is an optional step.
15. Turn on the **Data at rest encryption** toggle to enable encryption for data at rest. This is an optional step.
16. Turn on the Data tiering toggle to enable data tiering to be able to offload data to cold tier. This is an optional step.
 - a) If you enable data tiering, select tiering type. On selecting tiering type as **Remote archiving(Cold)**, you can offload data to a cold tier.
 - b) If you have selected **Remote archiving (cold)**, select the **Storage policy** and the **Remote Target**. You can create a new storage policy and/or a remote target by clicking Create new under the respective dropdowns.
17. Click **Create**.

Results

The mirror volume is created.

NOTE: Alternatively, you can click the volume to mirror in Resources list, and click **Actions > Create mirror**

Related maprcli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprcli` command. The command is provided for general reference. For more information, see [maprcli Commands in This Guide](#).

- `volume create`

Converting Standard Volume to Mirror Volume

Prerequisites

- You must be a fabric user to convert a standard volume to a mirror volume.
- The standard volume must have an associated mirror volume that can serve as the source volume.

About this task

You can convert a standard volume to a mirror volume and set it up to mirror one of its associated mirror volumes.

NOTE: The standard volume, when converted, can only be a mirror of one of its associated mirror volumes.

Follow the steps given below to convert a standard volume to a mirror volume.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. Click the Volume name under the respective fabric.
5. Click the **Actions** menu seen on the top right of the tabs displaying the volume details.
6. Click **Make Mirror**.
7. Select the **Source fabric** that has the mirror volume that the converted volume would mirror.
8. Select the **Source volume** that the converted volume will mirror.
9. Click **Save**.

Results

The source fabric is converted into a read-only mirror of the selected source volume on the selected source fabric with the existing name.

You can associate a mirroring schedule with this volume to ensure that data on the volume is in sync with the source volume.

Editing a Volume

Edit accountable entity, volume access for accountable entity and volume hard quota.

Prerequisites

- You must have the permission to edit the volume.

About this task

You can edit details such as hard quota, read/write access and accountable entity, when you edit a volume via the Data Fabric UI.

Follow the steps given below to edit volume properties.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. Expand the resources for the fabric containing the volume to edit.
5. Click the volume name seen under **Resource Name**.
6. Navigate to **Settings** tab for the volume.
7. Click the pencil/Edit icon next to **Properties** to edit the accountable entity and/or volume access as read or read/write. Click Save. This is an optional step.
8. Click the pencil/Edit icon next to **Quota** to edit the hard quota for the volume. This is an optional step.
9. Click **Save**.

Results

The volume is edited successfully.

Setting a Volume Quota

Set space quota for volume.

Prerequisites

You must have be a fabric user to configure or set volume quota.

About this task

You can set hard quota for volume via the Data Fabric UI.

NOTE: It is recommended to set advisory quota for a volume. See [Setting advisory quota via CLI](#) to set advisory quota. An alarm is set off when advisory quota is reached or exceeded.

Use the following steps to set the volume quota.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.

3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the volume to set the quota for.
5. Click the volume name seen under **Resource Name**.
6. Navigate to the **Settings** tab.
7. Click the Edit icon seen next to **Quota**.
8. Enter the value and select the unit of measurement for the quota.
9. Click **Save**.

Results

The hard quota for the volume is set.

Data on the volume cannot occupy space higher than the quota. If the data on the volume exceeds the hard quota, an alarm is raised.

Configuring Data Access Control for Volume

Configure access to data on a volume.

Prerequisites

The following prerequisites must be met before attempting to configure data access control for a volume.

- The user or group, for which you wish to assign permissions, must exist for the fabric.
- You must have be a fabric user or fabric manager to configure data access for the volume.

About this task

Configure or control access to data on a volume.

There are three user types that can be assigned access to data on a volume. The user types are as follows.

- Public - Public refers to all users.
- User - A user is an individual user that uses the Data Fabric UI.
- Group - Groups are collection of users that are categorized based on a commonality such as department or location.

You can assign read or write permissions to public or to specific users and/or groups. By default, read and write permissions are assigned to all users.

When a read or write permission is assigned to public, it implies that all users and groups are able to read data from and write data to the volume in question.

NOTE: A write permission assigned to a user type implies that the respective user type has both read and write permissions on the volume.

If you wish to assign read or write permission to specific users and/or groups, you must first remove any permission assigned to the public user type. You cannot assign read or write permissions to specific users and/or groups when the respective permissions are assigned to public.

To configure data access control for a volume, follow these steps:

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the volume to edit.
5. Click the volume name seen under **Resource Name**.
6. Click the **Settings** tab.
7. Click the Edit icon seen next to **Data Access Control**.
8. Click **Add** to add permissions for a user or a group.
9. Select user or group from the **Type** dropdown.
10. Enter the name of the user or group to which you wish to assign the permission or permissions.
11. Select read and/or write checkbox depending on the permission you wish to assign to the user or the group.
12. Repeat the steps related to adding user/group and assigning permissions to them, as necessary.
13. Click **Save**.

Results

Permissions are assigned to the respective users and/or groups.

Configuring Volume Administration Settings

Configure volume access control for various user types.

Prerequisites

The following prerequisites must be met before you can configure volume administration settings for users and groups.

- You must have be a fabric manager to perform the operation.
- The users and groups must have been created before you can assign various volume-related permissions.

About this task

You can assign various permissions related to a volume to specific users and/or groups.

The following permissions with respect to a volume can be assigned to one or more users and/or groups.

- Edit permission
- Admin permission to manage access control to volume and data on the volume
- Restore and mirror permission
- Delete permission
- Full control, which means, all the aforementioned permissions.

Follow the steps given below to configure volume administration settings.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the volume to configure.
5. Click the volume name seen under **Resource Name**.
6. Click the **Settings** tab.
7. Click the edit icon seen next to **Volume Admin Control**.
8. Click **Add** to add permissions for a user or a group.
9. Select user or group from the **Type** dropdown.
10. Enter the name of the user or group to which you wish to assign the permission or permissions.
11. Select the checkbox or checkboxes for the permission(s) that you wish to assign to the user or the group.
12. Repeat the steps related to adding user/group and assigning permissions to them, as necessary.
13. Click **Save**.

Results

Permissions are assigned to the respective users and/or groups.

Renaming a Volume

Rename a volume.

Prerequisites

- You must have the permission to rename a volume.

About this task

You can rename a volume associated with a fabric, by using the Data Fabric UI. You can rename only one volume at a time.

Follow the steps given below to rename a volume.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the volume to rename.
5. Click the volume name seen under **Resource Name**.
6. Click the ellipsis under **Actions** for the volume.
7. Click the **Rename** option.

8. Enter the new name for the volume and click **Save**.

Results

The volume is renamed successfully.

Related maprcli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprcli` command. The command is provided for general reference. For more information, see [maprcli Commands in This Guide](#).

- `volume rename`

Viewing Volume Endpoint Information

View volume endpoint information.

Prerequisites

You must be a fabric user to perform this operation.

About this task

You can view volume endpoint information from the Data Fabric UI.

This can be used in scripts to make API calls to access the volume.

Follow the steps given below to view volume endpoint information.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the volume.
5. Click the ellipsis under **Actions** for the required volume.
6. Click the **View endpoint** option.

Results

The volume endpoint information is displayed.

Viewing Object Endpoint Info to Remotely Access Files as Objects

View endpoint information for files in a volume to be able to access the files as objects when accessed by S3 client.

Prerequisites

You must be a fabric user to perform this operation.

About this task

A volume contains one or more files. The files in a volume can be accessed as objects by an S3 client, via the endpoints provided by Data Fabric. You can view the object endpoints from the Data Fabric UI.

The object endpoints for files can be used to make API calls in scripts for S3 clients to access files in the volume.

Follow the steps given below to view object endpoint information for files in a volume.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the volume.
5. Click the ellipsis under **Actions** for the required volume.
6. Click the **View endpoint** option.

Results

You are able to view the volume endpoint and object endpoint information corresponding to the files on the volume.

Downloading Volume Endpoint Information

Download JSON file containing endpoint information for the selected volume endpoint information.

Prerequisites

You must be a fabric user to perform this operation.

About this task

You can download the endpoint information for a selected volume. The downloaded volume endpoint information is available as a JSON file.

NOTE: You can view object endpoints for files on the Data Fabric UI. Only volume endpoint information is downloadable.

Follow the steps given below to download information related to volume endpoint.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the volume.
5. Click the ellipsis under **Actions** for the required volume.
6. Click the **View endpoint** option.
7. Click **Download** on the Endpoints dialog box.

Results

A JSON file containing the volume endpoint information for the selected volume is downloaded to your local downloads folder.

Configuring Data Access Control for Volume

Configure access to data on a volume.

Prerequisites

The following prerequisites must be met before attempting to configure data access control for a volume.

- The user or group, for which you wish to assign permissions, must exist for the fabric.
- You must have be a fabric user or fabric manager to configure data access for the volume.

About this task

Configure or control access to data on a volume.

There are three user types that can be assigned access to data on a volume. The user types are as follows.

- **Public** - Public refers to all users.
- **User** - A user is an individual user that uses the Data Fabric UI.
- **Group** - Groups are collection of users that are categorized based on a commonality such as department or location.

You can assign read or write permissions to public or to specific users and/or groups. By default, read and write permissions are assigned to all users.

When a read or write permission is assigned to public, it implies that all users and groups are able to read data from and write data to the volume in question.

NOTE: A write permission assigned to a user type implies that the respective user type has both read and write permissions on the volume.

If you wish to assign read or write permission to specific users and/or groups, you must first remove any permission assigned to the public user type. You cannot assign read or write permissions to specific users and/or groups when the respective permissions are assigned to public.

To configure data access control for a volume, follow these steps:

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the volume to edit.
5. Click the volume name seen under **Resource Name**.
6. Click the **Settings** tab.
7. Click the Edit icon seen next to **Data Access Control**.
8. Click **Add** to add permissions for a user or a group.
9. Select user or group from the **Type** dropdown.
10. Enter the name of the user or group to which you wish to assign the permission or permissions.
11. Select read and/or write checkbox depending on the permission you wish to assign to the user or the group.
12. Repeat the steps related to adding user/group and assigning permissions to them, as necessary.

13. Click **Save**.

Results

Permissions are assigned to the respective users and/or groups.

Deleting a Volume

Delete a single volume.

Prerequisites

- You must be a fabric user to perform this operation.

About this task

You can delete a volume associated with a fabric, via the Data Fabric UI. Once the volume is deleted, the data on the volume is lost unless you have a backup of the data on the volume.

Follow the steps below to delete a volume.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the volume to delete.
5. Click the volume name seen under **Resource Name**.
6. Click the ellipsis under **Actions** for the volume.
7. Click the **Delete** option.
8. Click **Delete** to confirm volume deletion.

Results

The volume is permanently deleted, along with the data stored on the volume.

Related maprccli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprccli` command. The command is provided for general reference. For more information, see [maprccli Commands in This Guide](#).

- `volume delete`

Administering Volume Snapshots

Snapshot overview and administering snapshots.

Snapshot Basics

A snapshot is a static or read-only view of a volume that represents the state of the volume at the point in time of the snapshot creation. Because a snapshot is not a replica of a volume, it does not occupy much space on the volume.

A snapshot takes no time to create, and initially uses no disk space, because it stores only the incremental changes needed to roll the volume back to the state at the time the snapshot was created. The storage used by a volume's snapshots does not count against the volume's quota.

A snapshot can be used to restore volume data to the state the volume data at the time of the snapshot creation.

You can use a snapshot for the following purposes.

- Snapshots enable you to roll back to a known good data set and recover data in case of data corruption or accidental deletions, without the help of storage administrators. For example, before performing a risky operation on a volume, you can create a snapshot to enable rollback capability for the entire volume.
- Create static data sets for querying and auditing.

Snapshots are stored in the `.snapshot` directory on the volume mount path.

You can access snapshots via NFS or the Hadoop shell.

You can create a snapshot manually, or automate the process with a schedule. If you wish to schedule the creation of snapshots, you must assign a predefined schedule.

Schedules for Volume Snapshots

Describes schedules for snapshots

About Schedule

A schedule to capture snapshots of volume data can be created and assigned to volumes.

Data Fabric provides pre-defined schedules that can be applied to volumes.

Predefined schedules are classified into three categories depending on the type of data in the volume you wish to back up with a snapshot.

You can select a pre-defined schedule for a volume, depending on the type of data that the volume contains.

If the volume data needs to be backed up very frequently as a snapshot, select the critical data schedule.

If it suffices to back up volume data less frequently, select the normal data schedule.

Table

Pre-defined Schedule	Frequency and Retention Period	Comments
Critical Data	<ul style="list-style-type: none"> • Hourly - Retained for 24 hours • Daily at 12:00 AM - Retained for 7 days • Weekly every Sunday at 12:00 AM - Retained for 12 weeks 	<p>Use for volumes with data that might be changing constantly and/or needs to be frequently backed up.</p> <p>If you wish to preserve the snapshot beyond the default retention period per schedule, you can preserve the snapshot.</p>

Table (Continued)

Pre-defined Schedule	Frequency and Retention Period	Comments
Important Data	<ul style="list-style-type: none"> Daily at 6:00 AM - Retained for 24 hours Daily at 12:00 PM - Retained for 24 hours Daily at 6:00 PM - Retained for 24 hours Daily at 12:00 AM - Retained for 7 Days Weekly every Sunday at 12:00 AM - Retained for 4 weeks Monthly every first day of the month at 12:00 AM - Retained for 2 months 	Use for volumes containing data that needs to be backed up frequently during the day and week. If you wish to preserve the snapshot beyond the default retention period per schedule, you can preserve the snapshot.
Normal Data	<ul style="list-style-type: none"> Daily at 12:00 AM - Retained for 7 days weekly every Sunday 12:00 AM - Retained for 4 weeks Monthly every first day of the month at 12:00 AM - Retained for 2 months 	<p>Use for volumes for volumes containing data that changes infrequently or does not need to be backed up frequently.</p> <p>If you wish to preserve the snapshot beyond the default retention period per schedule, you can preserve the snapshot.</p>

When you specify a snapshot schedule on a mirror volume, it specifies how often to take a snapshot of the mirror volume. This snapshot schedule is distinct from the snapshot schedule for the standard volume.

A snapshot schedule for a promotable mirror volume has two purposes:

- The schedule specifies how often to take a snapshot of the mirror volume for the purpose of preserving the state of the mirror before a subsequent mirror operation. This way, if corrupt data is copied from the source volume's snapshot into the mirror volume, the mirror contents can be rolled back to the snapshot.
- If the promotable mirror volume is promoted to a read-write volume, the snapshot schedule specified for the mirror is used for the promoted read-write volume. Once a mirror volume is promoted to a read-write volume, the mirror schedule is disabled.

Creating a Volume Snapshot

Create volume snapshot manually via Data Fabric UI.

Prerequisites

- You must be a fabric user to create a volume snapshot.

About this task

A snapshot is a read-only image of a volume that provides point-in-time recovery of the volume if data on the volume gets corrupted or is lost due to some reason. Snapshots store changes to the data present in the volume. A snapshot preserves access to historical data and facilitates data retrieval, when data is lost due to user errors and application errors.

You can create a snapshot manually, or automate the process with a schedule. Snapshots are stored in the `.snapshots` directory. You can always view snapshots from this directory.

The maximum number of snapshots that you can create for each volume is 4092. Exceeding this limit raises the snapshot failure alarm with an appropriate entry in the CLDB logs.

Follow the steps given below to create a snapshot manually via the Data Fabric UI.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the volume to snapshot.
5. Click the volume name seen under **Resource Name**.
6. Navigate to the **Snapshots** tab.
7. Click **Create** seen on the top right side of the tab.
8. Enter a name for the volume snapshot or retain the default name.
9. Click **Save**.

Results

The volume snapshot is successfully created. The snapshot is added to the list of snapshots seen on the **Snapshots** tab.

Related maprcli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprcli` command. The command is provided for general reference. For more information, see [maprcli Commands in This Guide](#).

- `volume snapshot create`

Scheduling Volume Snapshots

Assign schedule to volume for creation of volume snapshots.

Prerequisites

- You must be a fabric user to assign a schedule to volume to take a volume snapshot.
- The volume to assign the pre-defined schedule to must be a standard volume.

About this task

You can assign a pre-defined schedule to a standard volume to take volume snapshots. See [Schedules for Volume Snapshots](#) on page 1205 for details on pre-defined schedules.

Follow the steps given below to schedule volume snapshot.

Procedure

1. Log on to the Data Fabric UI.

2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the volume to snapshot.
5. Click the volume name seen under **Resource Name**.
6. Navigate to the **Settings** tab.
7. Under **Schedules**, click the Edit icon seen next to **Snapshots**.
8. Select a suitable schedule option for the volume.
9. Click **Select**.

Results

The selected schedule is applied to the volume and snapshots are taken per schedule. The snapshots are stored in the .snapshot's directory of the volume mount path.

Preserving a Volume Snapshot

Preserve a volume snapshot.

Prerequisites

- You must be a fabric user to preserve a volume snapshot.

About this task

You can preserve a volume snapshot if you wish to store a volume snapshot beyond the retention period defined during its creation.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the volume whose snapshot is to be preserved.
5. Click the volume name seen under **Resource Name**.
6. Navigate to the **Snapshots** tab.
7. Select the checkbox for the snapshot to preserve.
8. Click the down arrow next to **Actions** seen on the top right side of the tab. Alternatively,
9. Click the **Preserve** menu option.
10. Click **Preserve** on the message box that appears.

Results

The volume snapshot is preserved successfully. A message informing you about successful preservation of snapshot is displayed on the Data Fabric UI.

The volume snapshot can be accessed from the .snapshot directory on the volume mount path.

Related maprcli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprcli` command. The command is provided for general reference. For more information, see [maprcli Commands in This Guide](#).

- [volume snapshot preserve](#)

Restoring a Volume from a Volume Snapshot

Describes how to restore a volume from a volume snapshot.

Prerequisites

- You must be a fabric user to restore a volume from the volume snapshot.

About this task

You can restore volume data to a specific point in time with volume snapshots.

Follow the steps given below to restore a volume from a volume snapshot.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the volume whose snapshot is to be restored.
5. Click the volume name seen under **Resource Name**.
6. Navigate to the **Snapshots** tab.
7. Select the checkbox for the snapshot from which you wish to restore the volume.
8. Click the ellipsis seen next to the snapshot to restore from.
9. Click the **Restore** menu option.
10. Click **Restore** on the message box that appears.

Results

The volume is restored from the snapshot. A message informing you about successful restoration of volume is displayed on the Data Fabric UI.

The volume snapshot is preserved indefinitely in the `.snapshot` directory on the volume mount path.

Related maprcli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprcli` command. The command is provided for general reference. For more information, see [maprcli Commands in This Guide](#).

- [volume snapshot restore](#)

Deleting a Volume Snapshot

Delete a volume snapshot.

Prerequisites

- You must be a fabric user to delete a volume snapshot.

About this task

You can delete a volume snapshot manually, if you no longer wish to retain the volume snapshot.

NOTE: A volume snapshot is deleted automatically when the retention period for the volume snapshot ends.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the volume whose snapshot is to be preserved.
5. Click the volume name seen under **Resource Name**.
6. Navigate to the **Snapshots** tab.
7. Select the checkbox for the snapshot to delete.
8. Click the down arrow next to **Actions** seen on the top right side of the tab.
9. Click the **Delete** menu option.
10. Click **Delete** on the message box that appears.

Results

The volume snapshot is deleted successfully. The volume snapshot is removed from the . snapshot folder. You are no longer able to access or use the volume snapshot. The data on the volume referred to by the snapshot remains intact, only the static view pointing to the volume data is deleted.

Related maprccli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprccli` command. The command is provided for general reference. For more information, see [maprccli Commands in This Guide](#).

- `volume snapshot remove`

Data Tiering

Conceptual information about data tiering.

Data that is active and frequently accessed is categorized as hot data.

Data that is rarely accessed is categorized as warm data or cold data.

Hot data, warm data, and cold data is identified based on the rules and policies set on by the administrator.

The storage used to store hot data is referred to as the hot-tier. The storage used to store warm data is referred to as an EC-tier, and the mechanism to store cold data is referred to as the cold tier.

Data starts off as hot data when it is first written to local storage on a fabric. Data can be termed as warm or cold based on the storage policies that are configured for the data present on Data Fabric.

Data stored on a fabric requires three times the amount of disk space of the regular volume on premium hardware due to replication (default being 3). After offloading to the cloud, the space used by data (including data in the namespace container) in the volume on the data fabric cluster is freed and only the metadata of the volume in the namespace container is 3-way replicated on the data fabric cluster.

Data can be set up to be automatically offloaded to a volume on a low-cost storage alternative, called a warm tier, on the data fabric cluster. Alternatively, data can be offloaded to a low-cost storage on a third party cloud object store, called a cold tier, like S3.

Data Fabric provides rule-based automated tiering functionality that allows you to seamlessly integrate with:

- Low-cost storage as an additional storage tier in the data fabric cluster for storing file data that is less frequently accessed (warm data) in erasure-coded volume.
- 3rd party cloud object storage as an additional storage tier in the data fabric cluster to store file data that is rarely accessed or archived (cold data).

In this way, valuable on-premise storage resources can be used for more active or hot file data and applications, while warm and/or cold file data can be retained at minimum cost for compliance, historical, or other business reasons. The data fabric provides consistent and simplified access to and management of the data.

Data, once offloaded, is purged on the the data fabric cluster to release the disk space. When you delete an entire file, part of a file, or a snapshot, corresponding objects are removed from the tier

When a client tries to read offloaded data, the data fabric processes the read request of the warm-tiered and cold-tiered standard and mirror volume data differently. Similarly, when a client writes to a tiered volume, the data fabric processes appends and overwrites differently.

To manage data offloading, you must have created storage policies. See [Administering Storage Policies](#) on page 1214 to learn more about managing storage policies.

To offload data, you must create remote targets. See [Creating a Remote Target](#) on page 1219 to add a new remote target.

You can schedule data offloading. See [Creating a Schedule](#) on page 1222 for further information on creating a schedule.

Schedules for Volume Data Tiering

Describes schedules for data tiering of volume data

About Schedule

A schedule to capture snapshots of volume data can be created and assigned to volumes.

Data Fabric provides predefined schedules that can be applied to volumes.

Predefined schedules are classified into three categories depending on the type of data in the volume you wish to back up with a snapshot.

You can select a pre-defined schedule for a volume, depending on the type of data that the volume contains.

If the volume data needs to be backed up very frequently as a snapshot, select the critical data schedule.

If it suffices to back up volume data less frequently, select the normal data schedule.

Table

Pre-defined Schedule	Frequency and Retention Period	Comments
Critical Data	<ul style="list-style-type: none"> Hourly - Retained for 24 hours Daily at 12:00 AM - Retained for 7 days Weekly every Sunday at 12:00 AM - Retained for 12 weeks 	<p>Use for volumes with data that might be changing constantly and/or needs to be frequently backed up.</p> <p>If you wish to preserve the snapshot beyond the default retention period per schedule, you can preserve the snapshot.</p>
Important Data	<ul style="list-style-type: none"> Daily at 6:00 AM - Retained for 24 hours Daily at 12:00 PM - Retained for 24 hours Daily at 6:00 PM - Retained for 24 hours Daily at 12:00 AM - Retained for 7 Days Weekly every Sunday at 12:00 AM - Retained for 4 weeks Monthly every first day of the month at 12:00 AM - Retained for 2 months 	<p>Use for volumes containing data that needs to be backed up frequently during the day and week. If you wish to preserve the snapshot beyond the default retention period per schedule, you can preserve the snapshot.</p>
Normal Data	<ul style="list-style-type: none"> Daily at 12:00 AM - Retained for 7 days weekly every Sunday 12:00 AM - Retained for 4 weeks Monthly every first day of the month at 12:00 AM - Retained for 2 months 	<p>Use for volumes for volumes containing data that changes infrequently or does not need to be backed up frequently.</p> <p>If you wish to preserve the snapshot beyond the default retention period per schedule, you can preserve the snapshot.</p>

When you specify a snapshot schedule on a mirror volume, it specifies how often to take a snapshot of the mirror volume. This snapshot schedule is distinct from the snapshot schedule for the standard volume.

A snapshot schedule for a promotable mirror volume has two purposes:

- The schedule specifies how often to take a snapshot of the mirror volume for the purpose of preserving the state of the mirror before a subsequent mirror operation. This way, if corrupt data is copied from the source volume's snapshot into the mirror volume, the mirror contents can be rolled back to the snapshot.
- If the promotable mirror volume is promoted to a read-write volume, the snapshot schedule specified for the mirror is used for the promoted read-write volume. Once a mirror volume is promoted to a read-write volume, the mirror schedule is disabled.

Manually Offloading Data to a Cold Tier

Prerequisites

- You must be a fabric user to perform this operation.
- Data tiering must have been enabled on the volume during the volume creation, to be able to offload/recall data.

- To offload data, you must create remote targets. See [Creating a Remote Target](#) on page 1219 to add a new remote target.
- To manage data offloading, you must have created storage policies. See [Administering Storage Policies](#) on page 1214 to learn more about managing storage policies.

About this task

Data, once offloaded, is purged on the the data fabric cluster to release the disk space. When you delete an entire file, part of a file, or a snapshot, corresponding objects are removed from the tier.

Data is offloaded to the tier in the same state, compressed or uncompressed, as was stored in the front-end volume. If data encryption is enabled on the front-end volume (using the `dare` parameter), data is encrypted during and after offload.

At the volume level, data can be offloaded manually by triggering the offload operation.

Follow the steps given below to offload data manually from a volume to a cold tier.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the volume.
5. Click the ellipsis under **Actions** for the required volume.
6. Select **Offload data**.

Results

The data offload begins to the designated cold tier.

Recalling Data to the Data Fabric File System

Prerequisites

- You must be a fabric manager or a fabric user to perform this operation.
- Data tiering must have been enabled on the volume during the volume creation, to be able to offload/recall data.
- Offloaded data must be present on the cold tier.

About this task

When you read data that has been offloaded to a remote target (or cold tier), data is automatically recalled to the file system to allow the read to succeed.

The recalled data is automatically:

- Purged based on the expiration time period set at the volume level for recalled data if there are no changes (for example, read operation).
- Offloaded based on the rule and the expiration time period set at the volume level for recalled data if there are changes (for example, overwrite operation).

For a cold tiering volume, you must explicitly recall the volume before running any analytics jobs.

Follow the steps given below to recall data manually from a volume to a cold tier.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the volume.
5. Click the ellipsis under **Actions** for the required volume.
6. Select **Recall data**.

Results

The data recall operation begins and data is recalled on to the fabric file system.

Administering Storage Policies

Manage storage policies related to data tiering.

You can configure a storage policy (or rules) for data at the volume level.

A storage policy simplifies the lifecycle management of data in the volume including automated migration of files to low-cost storage alternatives. A storage policy contains rules for files that have a well-defined lifecycle or for files you want to switch to different storage tiers during their lifecycle.

You can specify the rules, at the volume level, to selectively identify files to offload (such as file size, file owner, and file modification time), the schedule for offloading the data (for example, two months after file modification), and the settings for storing (such as the location and credentials for the tier) and recalling the offloaded data. You can configure one rule per volume. You can also associate a schedule to automatically offload data at scheduled intervals based on the associated rules.

Data offload is driven by rules, which are configured per volume. Data offload rule can be based on size of file (s), owner (u, g, or p) of the file, and/or file modification timestamp (m). You can apply one rule per volume.

When a rule is associated with a volume, the rule is first applied on the files in the tiering-enabled volume. When applied on the files in the tiering-enabled volume, the offload is triggered for all files in the snapshot chain as well when the criteria in the rule is met. If the file does not exist in the tiering-enabled volume, rule is applied on the latest state of the file in the snapshot chain. If the file exists in the tiering-enabled volume but has no latest state or if the file was deleted in the tiering-enabled volume, offload does not happen.

Rules can be defined using a combination of the following:

u	Username or user ID, as configured in the OS registry (such as /etc/passwd file, LDAP, etc.), of a specific user. Usage: u:<username or user ID>
g	Group name or group ID, as configured in the OS registry (such as /etc/group file, LDAP, etc.), of a specific group. Usage: g:<groupname or group ID>

a	<p>(<i>atime</i>) Time (in seconds or days) since the files were last accessed. The number of seconds can be specified by appending <i>s</i> to value and the number of days can be specified by appending <i>d</i> to the value.</p> <p>Usage:</p> <p>NOTE: If the system time on CLDB and file server nodes are different, the <i>atime</i> rule for offloading data may not work as intended.</p> <p>This tier rule is matched and files are offloaded, when all of the following conditions are met:</p> <p>Assume that the <i>atime</i> feature is enabled on the volume and that the time in the rule is set to a:300s. Based on this rule, all files that are not accessed since 300s, are offloaded. However, this rule is valid only if time since <i>atime</i> tracking is enabled, is more than 300s. The volume level parameter <i>atimeTrackingStartTime</i> denotes the start time of <i>atime</i>.</p> <p>For more information, see Tuning Last Access Time.</p>
m	<p>(<i>mtime</i>) Time (in seconds or days) since the files were last modified. The number of seconds can be specified by appending <i>s</i> to value and the number of days can be specified by appending <i>d</i> to the value.</p> <p>Usage:</p> <p>All files that are not modified since the specified amount of time, are offloaded.NOTE: If the system time on CLDB and file server nodes are different, the <i>mtime</i> rule for offloading data may not work as intended.</p>
s	<p>The size of the file in bytes, kilobytes, megabytes, or gigabytes. The size of the file can be specified by appending one of the following to the value: <i>b</i> for bytes, <i>k</i> for kilobytes, <i>m</i> for megabytes, or <i>g</i> for gigabytes.</p> <p>Usage</p> <p>All files whose size exceeds the specified size are offloaded.</p>

Or, use the following:

p	(Default) Specifies all files. Specifies that this operation is applicable to all the files without restriction. This cannot be combined with any other operator.
""	Indicates none of the files. Specifies that this operation cannot be performed on any of the files.

Use the following to string multiple criteria for offload:

&	AND operation to combine multiple expressions as the criteria for the rule.
	OR operation to indicate either of the expressions as the criteria for the rule.
()	Delimiters for subexpressions.

Creating a Storage Policy

Prerequisites

You must be a fabric manager to perform this task.

About this task

The expression for a storage policy can comprise the following parameters:

- *u* denotes user.
- *g* denotes group.
- *s* denotes size. Append the value with the unit - *b*, *k*, *m*, *g* for bytes, KB, MB, or GB respectively.

- *m* denotes last modified time. Append the value with the unit - *s*, *d* for seconds or days respectively
- *a* denotes last accessed time. Append the value with the unit - *s*, *d* for seconds or days respectively.

Use & to add an AND condition and | to add an OR condition, to combine multiple parameter-value pairs.

Example: To offload data to cold tier for user *jdoe*, when storage size reaches *100 MB*, and the last accessed time is *7 days*, the expression is *u:jdoe&s:100m&a:7d*

Follow the steps given below to create a storage policy.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Fabric administration icon on the left pane.
3. Select from the **Select fabric** dropdown the fabric for which you wish to add the storage policy.
4. On the **Manage access** tab, scroll down to the **Storage policies** card.
5. Click **Create storage policy**.
6. Enter the **Name** for the storage policy.
7. Enter the expression for the storage policy.
8. Click **Create**.

Results

The storage policy is created successfully when you enter valid values and units for the parameters specified in the policy.

Editing a Storage Policy

About this task

You can modify the basic rule to:

- Add or remove users and/or groups.
- Change the name of the users and/or groups.
- Change the number of days since the file was last modified for users and/or groups.

If you switch from a basic rule to an advanced rule, all expressions from the basic rule are carried over to the advanced rule. You can modify an advanced rule using a combination of the following expressions:

u	Username or user ID, as configured in the OS registry (such as /etc/passwd file, LDAP, etc.), of a specific user. Usage: u:<username or user ID>
g	Group name or group ID, as configured in the OS registry (such as /etc/group file, LDAP, etc.), of a specific group. Usage: g:<groupname or group ID>

a	<p>(<i>atime</i>) Time (in seconds or days) since the files were last accessed. The number of seconds can be specified by appending <i>s</i> to value and the number of days can be specified by appending <i>d</i> to the value.</p> <p>Usage:</p> <ul style="list-style-type: none"> "a:<value>s" — specifies <i>atime</i> in seconds "a:<value>d" — specifies <i>atime</i> in days <p>NOTE: If the system time on CLDB and file server nodes are different, the <i>atime</i> rule for offloading data may not work as intended.</p> <p>This tier rule is matched and files are offloaded, when all of the following conditions are met:</p> <ol style="list-style-type: none"> 1. <i>atime</i> tracking is enabled at volume level 2. Time since <i>atime</i> that is configured on the volume is more than the time specified in the rule 3. Duration since the file was last accessed is more than the time specified in the rule <p>Assume that the <i>atime</i> feature is enabled on the volume and that the time in the rule is set to a:300s. Based on this rule, all files that are not accessed since 300s, are offloaded. However, this rule is valid only if time since <i>atime</i> tracking is enabled, is more than 300s. The volume level parameter <i>atimeTrackingStartTime</i> denotes the start time of <i>atime</i>. For more information, see Tuning Last Access Time.</p>
m	<p>(<i>mtime</i>) Time (in seconds or days) since the files were last modified. The number of seconds can be specified by appending <i>s</i> to value and the number of days can be specified by appending <i>d</i> to the value.</p> <p>Usage:</p> <ul style="list-style-type: none"> "m:<value>s" — specifies <i>mtime</i> in seconds "m:<value>d" — specifies <i>mtime</i> in days <p>All files that are not modified since the specified amount of time, are offloaded.NOTE: If the system time on CLDB and file server nodes are different, the <i>mtime</i> rule for offloading data may not work as intended.</p>
s	<p>The size of the file in bytes, kilobytes, megabytes, or gigabytes. The size of the file can be specified by appending one of the following to the value: <i>b</i> for bytes, <i>k</i> for kilobytes, <i>m</i> for megabytes, or <i>g</i> for gigabytes.</p> <p>Usage</p> <ul style="list-style-type: none"> "s:<value>b" — specifies file size in bytes "s:<value>k" — specifies file size in KB "s:<value>m" — specifies file size in MB "s:<value>g" — specifies file size in GB <p>All files whose size exceeds the specified size are offloaded.</p>

Or, use the following:

p	(Default) Specifies all files. Specifies that this operation is applicable to all the files without restriction. This cannot be combined with any other operator.
" "	Indicates none of the files. Specifies that this operation cannot be performed on any of the files.

Use the following to string multiple criteria for offload:

&	AND operation to combine multiple expressions as the criteria for the rule.
	OR operation to indicate either of the expressions as the criteria for the rule.
()	Delimiters for subexpressions.

You cannot switch from an advanced rule that includes the following to a basic rule because the following are not supported in a basic rule:

- p — All the files
- s — The size of the file
- & — The AND operation used for specifying multiple users (u), groups (g), or criteria
- | — The OR operation used with s or m
- "" — None of the files.
- () — Subexpressions

NOTE: The basic rule must contain mtime (m). It can also include one or more users or groups separated by the OR operation (|).

Follow the steps given below to edit a storage policy.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Fabric administration icon on the left pane.
3. Select from the **Select fabric** dropdown the fabric for which you wish to add the storage policy.
4. Scroll down to the **Storage policies** card.

NOTE: Alternatively, you can click **Global namespace**, click the fabric link in the table view, and navigate to the **Storage policies** tab for the fabric.

5. Click the ellipsis seen under **Actions** for the storage policy to edit.
6. Click **Edit**.
7. Make the required changes.
8. Click Save.

Results

The changes to the storage policy are saved successfully.

Deleting a Storage Policy

Delete storage policy.

Prerequisites

The storage policy must not be associated with a volume. A storage policy that is associated with a volume cannot be deleted.

About this task

You can delete a storage policy that is no longer required, and has no association with any volume on any fabric.

Follow the steps given below to delete a storage policy.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Fabric administration icon on the left pane.
3. Select from the **Select fabric** dropdown the fabric for which you wish to add the storage policy.
4. Scroll down to the **Storage policies** card.

NOTE: Alternatively, you can click **Global namespace**, click the fabric link in the table view, and navigate to the **Storage policies** tab for the fabric.

5. Click the ellipsis seen under **Actions** for the storage policy to edit.
6. Click **Delete**.
7. Confirm the deletion.

Results

The storage policy is deleted.

Administering Remote Targets

Data Fabric provides rule-based automated tiering functionality that allows you to seamlessly integrate with third party cloud object storage as an additional storage tier in the data fabric cluster to store file data that is rarely accessed or archived data, which is referred to as cold data. See

A cold tier is referred to as remote target on the Data Fabric UI.

The remote storage where cold data can be offloaded is called a remote target.

A remote target has a bucket on the third party cloud store where volume data is offloaded based on the policy configured by the fabric manager.

Volume data in 64KB data chunks is packed into 8MB sized objects and offloaded to the bucket on the tier and the corresponding volume metadata is stored in a visible tier-volume as HPE Data Fabric Database tables on the data fabric cluster. During writes and reads, volume data is recalled to the data fabric cluster, if necessary. Data written to the volume is periodically moved to the remote target, releasing the disk space on the filesystem.

You can associate a volume with a remote target.

For cold data, you can offload your cluster data to public, private, and hybrid clouds. You can offload data to remote cloud from vendors such as Amazon AWS, Google Cloud Platform, Microsoft Azure, IBM Cleversafe, Hitachi HCP, and Minio. You can tap into cloud-scale capacity for cold data.

NOTE: Data Fabric supports tiering for only file and volume data; tiering of tables and streams is not supported.

Creating a Remote Target

Create a remote target to offload cold data.

Prerequisites

You must be a fabric manager to perform this task.

About this task

You can create one or more remote targets to offload cold data to the remote target.

Follow the steps given below to create a remote target.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Fabric administration icon on the left pane.
3. Select from the **Select fabric** dropdown the fabric for which you wish to add the storage policy.
4. Select from the fabrics dropdown the fabric for which you wish to add a remote target.
5. Click the **Others** tab and scroll down to the **Remote targets** card.
6. Click **Create remote target**.
7. Enter the **Name** for the remote target.
8. Select a cloud provider from the **Vendor** dropdown.
9. Enter the **URL**.
10. Select the **Bucket**.
11. Enter the **Region**.
12. Enter the **Access key**.
13. Enter the **Secret key**.
14. Click **Create**.

Results

The remote target is created successfully.

The remote target can be used as a cold tier for data tiering. You can associate a volume with the remote target to offload the cold data from the volume on to the remote target.

Editing Remote Target Credentials

Edit credentials for a remote target.

Prerequisites

You must be a fabric manager to perform this operation.

About this task

You can edit the credentials for a remote target.

Follow the steps given below to edit remote target credentials.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Fabric administration icon on the left pane.
3. Select from the **Select fabric** dropdown the fabric for which you wish to to edit a remote target.

4. Click the **Others** tab and scroll down to the **Remote targets** card.
5. Click the ellipsis under **Actions** for the remote target whose credentials you wish to change.
6. Click **Edit Credentials**.
7. Modify the **Access key**, **Secret key** or both, as required.
8. Click **Save**.

Results

The updated credentials are saved for the remote target.

Deleting a Remote Target

Delete a remote target.

Prerequisites

You must be a fabric manager or an infrastructure admin to perform this operation.

The remote target to delete must not be associated with a volume.

About this task

You can delete a remote target that is not in use. Before you delete a remote target, ensure that the data on the remote target is backed up.

Follow the steps given below to delete a remote target.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Fabric administration icon on the left pane.
3. Select from the **Select fabric** dropdown the fabric for which you wish to delete a remote target..
4. Click the **Others** tab and scroll down to the **Remote targets** card.
5. Click the ellipsis under **Actions** for the remote target whose credentials you wish to delete.
6. Click **Delete**. Confirm the deletion.

Results

The remote target is deleted. The data on the cold tier is inaccessible. The remote target is no longer available for data tiering.

Administering Schedules

Introduction to schedules.

A schedule is a group of rules that specify recurring points in time at which certain actions are determined to occur. You can use schedules to automate the creation of snapshots and mirrors and the offload of volume data to a storage tier; after you create a schedule, it appears as a choice in the scheduling menu when you are creating or editing a volume.

When you specify a *snapshot* schedule on a mirror volume, it specifies how often to take a snapshot of the mirror volume. This snapshot schedule is distinct from the snapshot schedule for the standard volume. A snapshot schedule for a promotable mirror volume has two purposes:

- It specifies how often to take a snapshot of the mirror volume for the purpose of preserving the state of the mirror before a subsequent mirror operation. This way, if corrupt data is copied from the source volume's snapshot into the mirror volume, the mirror contents can be rolled back to the snapshot.

- If the promotable mirror volume is promoted to a read-write volume, the snapshot schedule specified for the mirror is used for the promoted read-write volume. Once a mirror volume is promoted to a read-write volume, the mirror schedule is disabled.

A *mirror* schedule specifies how frequently the mirror volume is synchronized with the source volume. In case of a disaster (or any type of data loss on a read-write source volume), the data can be recovered from the mirror volume, but any data written to the source volume since the last successful mirror operation will not be on the mirror volume. Therefore, you should set the mirror schedule such that it meets your RPO (Recovery Point Objective).

A *tier offload* schedule specifies how frequently data in the volume on the fabric is offloaded to the tiered storage. This setting to automatically offload data to the storage tier.

Creating a Schedule

Add a schedule for data tiering.

Prerequisites

You must be a fabric manager to perform this task.

About this task

A schedule is a group of rules that specify recurring points in time at which certain actions are determined to occur. You can use schedules to automate the creation of snapshots and mirrors. A schedule can be attached to a volume.

A schedule can have one or more rows.

A rule is made up of three elements.

- Frequency of the schedule such as yearly, daily, weekly, or specific time interval in minutes.
- Time at which schedule is to run
- Time period for which data is to be retained

Follow the steps given below to create a schedule.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Fabric administration icon on the left pane.
3. Select from the **Select fabric** dropdown the fabric for which you wish to create a schedule.
4. Click the **Others** tab and scroll down to the **Schedules** card.
5. Click **Create schedule**.
6. Enter the **Name** for the schedule.
7. Configure the rule. Select the frequency and time to trigger the schedule, and the data retention period.
8. Click **Create**.

Results

The schedule is created with the specified rule or rules.

Editing a Schedule

Edit an existing schedule.

Prerequisites

You must be a fabric manager to edit a schedule.

About this task

You can make changes to an existing schedule to incorporate any changes you wish to make to the schedule.

Follow the steps given below to edit a schedule.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Fabric administration icon on the left pane.
3. Select from the **Select fabric** dropdown the fabric for which you wish to edit a schedule.
4. Click the **Others** tab and scroll down to the **Schedules** card.
5. Click the pencil icon for the schedule to edit.
6. Make the necessary changes and click **Save**.

Results

The changes to the schedule are saved and the new schedule is applied to the data on the volumes to which the schedule applies.

Scheduling Volume Data Tiering

Schedule tiering for volume data.

About this task

After creating a schedule, you can associate it with the tiering-enabled volume when you create or modify the volume. If a schedule for offloading data is associated with the volume, data is offloaded automatically as scheduled based on the rules associated with the volume for offloading data.

For volumes enabled for cold tiering, you must assign a schedule to automatically offload data; if you do not assign a schedule, data is not offloaded automatically and you must manually run the offload command to offload data. See [Manually Offloading Data to a Cold Tier](#) on page 1212

for details on manually offloading data.

Follow the steps given below to schedule tiering of data on a volume.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the volume with which you wish to associate a data tiering schedule.
5. Click the volume name seen under **Resource name**.
6. Navigate to the **Settings** tab.
7. Under **Schedules**, click the pencil icon seen next to **Snapshots**.

8. Select a suitable schedule option for the volume.

9. Click **Select**.

Results

The selected schedule is applied to the volume and data tiering is done on the designated cold tier per schedule.

Viewing Schedules

View a list of schedules.

Prerequisites

You must be an infrastructure admin or a fabric manager to view the list of schedules.

About this task

You can view a list of all existing schedules to understand what the various schedules are. A fabric manager can decide if the required schedule already exists or it is required to create new schedules.

Follow the steps given below to view a schedule.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Fabric administration icon on the left pane.
3. Select from the **Select fabric** dropdown the fabric for which you wish to to edit a schedule.
4. Click the **Others** tab and scroll down to the **Schedules** card.

Results

You are able to see a list of existing schedules.

Deleting a Schedule

Delete a schedule.

Prerequisites

You must be a fabric manager to delete a schedule.

About this task

You can delete a schedule that is not associated with a volume.

TIP: Attach another schedule to a volume to overwrite the existing schedule (schedule to delete) attached to the volume. Once another schedule is attached, you can delete the old schedule.

Follow the steps given below to delete a schedule.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Fabric administration icon on the left pane.
3. Select from the **Select fabric** dropdown the fabric for which you wish to to edit a schedule.
4. Click the **Others** tab and scroll down to the **Schedules** card.
5. Click the bin icon for a schedule, to delete a schedule. Confirm the deletion.

Results

The schedule is deleted.

Mirroring

Synopsis of mirrors and mirroring process.

Creating a mirror volume is similar to creating a normal read/write volume. However, when you create a mirror volume, you must specify a source volume from which the mirror retrieves content. This retrieval is called the mirroring operation. Like a normal volume, a mirror volume has a configurable replication factor. Only one copy of the data is transmitted from the source volume to the mirror volume. Data Fabric volumes can only be mirrored and NOT replicated. However, the source and mirror volumes handle their own internal Data Fabric filesystem replication (which is based on the replication factor) independently. file system internally replicates source and mirror volumes independently of each other.

Volume mirroring from a lower Data Fabric version to higher Data Fabric version is supported. Volume mirroring from a higher Data Fabric version to a lower Data Fabric version is not supported.

Mirroring Process

The Data Fabric system creates a temporary snapshot of the source volume at the start of a mirroring operation. The mirroring process reads content from the snapshot into the mirror volume. The source volume remains available for read and write operations during the mirroring process.

If the mirroring operation is schedule-based, the snapshot expires according to the value of the schedule's **Retain For** parameter. Snapshots created during manual mirroring persist until they are deleted manually.

The mirroring process transmits only the differences between the source volume and the mirror. The initial mirroring operation copies the entire source volume, but subsequent mirroring operations can be extremely fast.

Local Mirroring

Describes local mirroring.

A *local mirror volume* is a mirror volume whose source is on the same cluster. Local mirror volumes are useful for load balancing or for providing a read-only copy of a data set.

You can locate your local mirror volumes in specific servers or on racks with particularly high bandwidth, mounted in a public directory separate from the source volume.

The most frequently accessed volumes in a cluster are likely to be the root volume and its immediate children. To load-balance read operations on these volumes, mirror the root volume (typically `mapr.cluster.root`, which is mounted at `/`). By mirroring these volumes, you can serve read requests from the mirrors, and distribute load across the nodes. Less-frequently accessed volumes that are lower in the hierarchy do not need mirror volumes. Since the mount paths for those volumes are not mirrored throughout, those volumes are writable.

If you are creating a local mirror of the root volume, `root(/)` points to the mirror volume, hence root is read-only. For read-write copy of root (`/`), you must use the special path, `/ .rw`

Remote Mirroring

Describes remote mirroring.

A remote mirror volume is a mirror volume with a source in another cluster. You can use remote mirrors for offsite backup, for data transfer to remote facilities, and for load and latency balancing for large websites. By mirroring the cluster's root volume and all other volumes in the cluster, you can create an entire mirrored cluster that keeps in sync with the source cluster.

Backup mirrors for disaster recovery can be located on physical media outside the cluster, or in a remote cluster. If disaster strikes the source cluster, you can check the time of last successful synchronization to determine the freshness of the backup.

Once data volumes are created in a primary data center, the Data Fabric administrator creates mirror volumes in a remote secondary data center.

Starting Volume Mirroring

Start mirroring of data on a mirror volume.

Prerequisites

- You must have created a mirror volume, on which you can mirror data from the source volume associated with the mirror volume.
- Data must be present on the source volume.

About this task

Data from the associated source volume can be mirrored to a mirror volume.

Follow the steps given below to start mirroring of data on to a mirror volume.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the volume.
5. Click the volume name seen under **Resource Name**.
6. Navigate to the **Mirrors** tab.
7. Click the ellipsis under **Actions** for the required volume.
8. Click the **Start mirroring** option, and click Start on the **Start mirroring** message box to confirm that you wish to start mirroring.

Results

Mirroring of data on the source volume is triggered. The status under the **Mirroring** column on Mirrors tab for the volume changes to **On**. The percentage of data mirrored from the source volume is displayed for the volume under the **Mirrored** column on the **Mirrors** tab.

Stopping Volume Mirroring

Stop mirroring of data that is in progress on a mirror volume.

Prerequisites

Data mirroring must be in progress on the mirror volume.

About this task

You can stop mirroring of data that is in progress from the associated source volume onto a mirror volume.

Follow the steps given below to stop mirroring of data on to a mirror volume.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.

4. In the tabular list of fabrics, click the down arrow for the fabric that contains the volume for which you wish to stop mirroring.
5. Click the volume name seen under **Resource Name**.
6. Navigate to the **Mirrors** tab.
7. Click the ellipsis under **Actions** for the volume being mirrored.
8. Click the **Stop mirroring** option.

Results

Mirroring of data that is in progress from the source volume onto the mirror volume is stopped. The status under the **Mirroring** column on Mirrors tab for the volume changes to **Off**.

Scheduling Volume Mirroring

Describes how to schedule mirroring of volume data.

Prerequisites

- You must have the privilege to schedule mirroring.
- The volume for which you are scheduling mirroring must be a mirror volume.

About this task

When you choose the mirror schedule, consider the amount of data on the volume and the load on the cluster. Remember that the mirroring frequency must allow enough time to complete one mirror operation before the next scheduled mirror operation starts. In addition, if you have a cascaded mirror setup (where A mirrors to B which mirrors to C), you cannot set a mirror schedule for C that starts before B finishes mirroring from A.

WARNING: Avoid setting a mirror schedule for more often than every 30 minutes.

Follow the steps given below to schedule mirroring on a volume.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the volume with which you wish to associate a mirroring schedule.
5. Click the volume name seen under **Resource name**.
6. Navigate to the **Settings** tab.
7. Under **Schedules**, click the pencil icon seen next to **Mirror**.
8. Select a suitable schedule option for the volume.
9. Click **Select**.

Results

The selected schedule is applied to the volume and data mirroring is performed per the schedule.

Auditing Fabric and Fabric Data

Auditing in Data Fabric.

You can enable auditing of cluster administration and data-access operations using the Data Fabric UI.

Levels of Auditing

There are two levels of auditing:

- Auditing for fabric-level administration operations
- Auditing of data access operations on the fabric

Enabling/Disabling Fabric Auditing

Enable or disable auditing on fabric.

About this task

Follow the steps given below to enable/disable auditing of fabric administration operations.

Procedure

1. Log on to the Data Fabric UI with Admin or Fabric Manager [credentials](#).
2. Click the All resources icon on the left pane, click the table view icon.
3. Click the link for the fabric in the Fabrics list for which you wish to enable auditing.
4. Navigate to the **Settings** tab on the fabrics page.
5. Under **Fabric settings**, click the Edit icon.
6. Toggle **Fabric auditing** to enable auditing on the fabric

Results

Auditing of fabric administration operations is enabled on the fabric. After auditing is enabled, audit log entries are generated when fabric administration operations are performed.

Configuring Auditing for Data Access Operation

Enable or disable auditing for data access operations on fabric.

About this task

Data access auditing can be enabled via the Data Fabric UI.

Follow the steps given below to audit data access operation on a fabric.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. Click the link for the fabric in the Fabrics list for which you wish to enable auditing.
5. Navigate to the **Settings** tab on the fabrics page.
6. Under **Fabric Settings**, click the Edit icon.
7. Select the **On** option for **Configure auditing of data-access operations**.

8. Enter the maximum size for the audit log.
9. Enter the retention period.
10. Click **Update**

Results

Auditing for data access operations is enabled on the fabric with the specified audit log size and retention period.

Administering Security Policies

Add, edit, delete, and manage state of security policies.

A security policy is an access control mechanism that can be applied to data objects on a fabric. Once a security policy is applied, it governs how a user can access data objects on the volume to which the security policy is applied.

A security policy can be associated with a volume.

TIP: A security policy is an access control mechanism for data stored on Data Fabric volumes, while a bucket policy is an access control mechanism applied to objects in an S3 object store associated with Data Fabric.

Security Policy Life Cycle

The state of a security policy is interpreted as a combination of two parameters:

- allow tagging
- access control

The following table explains the various values of the allow tagging and access control parameters.

Parameter	Accepted Values and Description	Default value
allow tagging	<p>false</p> <ul style="list-style-type: none"> Disables tagging; users cannot apply the security policy to data objects. This is the default setting when the fabric manager creates a security policy. The fabric manager can specify the setting explicitly when creating the security policy. When a security policy is active (allow tagging=true) but needs to be deprecated, modify the policy and set allow tagging=false. This prevents users from tagging any other data objects with the policy. Note that the system continues to enforce the security controls set in the security policy for data objects that were already tagged with the security policy. <p>true</p> <ul style="list-style-type: none"> Enables tagging; users can apply the security policy to data objects. When creating or modifying a security policy, a fabric manager can set allowtagging to true. When creating a security policy, as a fabric manager, you may want to set this parameter to true to test the security settings in the policy or to use tagging tools to discover data content and tag the data. To enable a deprecated security policy, set allow tagging to true. 	false

Parameter	Accepted Values and Description	Default value
access control	<p>Disarmed</p> <ul style="list-style-type: none"> Unless the fabric manager changes the setting when creating the security policy, this is the default setting if the fabric manager creates a security policy. The system does not enforce the access permissions set in the security policy during data operations on the data objects tagged with the security policy. <p>Armed</p> <ul style="list-style-type: none"> The system enforces the permissions set in the security policy during data operations on the data objects tagged with the security policy. When creating or modifying a security policy, as a fabric manager, you can set access control to Armed. To enforce access permissions set in a deprecated security policy, the fabric manager can set access control to Armed. The system continues to enforce access permissions set in the security policy for all data operations on the data objects tagged with the policy. <p>Denied</p> <ul style="list-style-type: none"> Denies all access to data objects tagged with the security policy. 	Disarmed

You can change the state of a security policy through the `allow_tagging` and `access_control` parameters to move a security policy through a life cycle, as shown in the following image where the security policy moves from new to retired.

The following table describes each of the stages in the security policy life cycle:

Stage	Description
new (default)	<ul style="list-style-type: none"> Default upon security policy creation. Users cannot tag data objects with the security policy. The system does not enforce access permissions set in the security policy
in use	<ul style="list-style-type: none"> Users can tag data objects with the security policy. The system enforces all security controls set in the security policy during data operations on data objects tagged with the security policy. Security controls set in the policy can include access permissions, auditing, and wire-level encryption.
deprecated	<ul style="list-style-type: none"> Users can no longer tag the security policy to data objects. The system still enforces the security controls set in the security policy for all data operations on the data objects tagged with the policy. Users cannot tag any additional data objects with the policy.
retired	<ul style="list-style-type: none"> Users cannot tag the security policy to data objects. All data operations on the data objects tagged with the security policy are denied by the system.

About Security Policy Domain

Describes a security policy domain.

A security policy domain is a group of fabrics that directly or indirectly share data and use the same security policies to control access to the data. A security policy domain consists of one master fabric and zero or more member security policy fabrics that create a global security policy namespace.

A global policy master is a prerequisite for the creation of security policies. A global policy master is a fabric on which security policies can be created.

You can create and modify security policies only on the fabric that is designated as the global policy master. When you create or update security policies, the policy server updates the `mapr.pbs.base` volume with the security policy metadata. Subsequently, the security policies are mirrored to other member fabrics in the global namespace.

By default, the first fabric or the primary fabric that you create on the global namespace is designated as the global policy master. Hence, it is not required to explicitly assign an alternate global policy master, unless the primary fabric goes down.

Each fabric, to which a security policy is applied, operates independently and, therefore, does not require network connectivity to the global policy master to enforce policies. A security policy server in each of the fabrics enforces the policies and manages the security policy metadata in an internal volume named `mapr.pbs.base`.

See [Security Policy Implementation Workflow](#) on page 1233 for details on how to apply security policies to fabric volumes on Data Fabric.

Security Policy Implementation Workflow

Describes the security policy workflow, in general, and the steps in implementing a security policy.

In the diagram below, all member fabrics, that is, Member Fabric 1, Member Fabric 2, Member Fabric 3, and Member Fabric 4 get the policy metadata from the global policy master.

The security policies are mirrored to all member fabrics in the global namespace from the global policy master.

1 – Create a Security Policy Domain

By default, the primary fabric is set as the global policy master and all secondary fabrics are member fabrics in the global namespace, with respect to security policies. You must create security policies on

the primary fabric as security policies are propagated to secondary fabrics or member fabrics by way of mirroring of the security policies. The mirroring takes place every 15 minutes.

IMPORTANT: If a primary fabric needs to go offline or fails, set one of the member fabrics as the new primary fabric.

Use the following command to set a member fabric as the primary fabric.

```
maprcli clustergroup updateprimary -clustername <specify actual fabric name here>
```

Once a new member fabric is converted into a primary cluster, it automatically becomes the global policy master.

To identify if a fabric is the global policy master, run the following command on the command line for the fabric:

```
maprcli config load --keys "cldb.pbs.global.master"
```

The value of `cldb.pbs.global.master` is 1 in the output of the aforementioned command, for the fabric that is designated as the global policy master. For a member fabric, the value is 0.

2 - Create and Update Security Policies

You can create and update security policies on the global policy master only. You cannot create or modify security policies on member fabrics. See [Creating a Security Policy](#) on page 1243 for instructions to create a security policy.

The following table lists the operations you can and cannot perform on the global policy master and member security-policy fabrics:

Security-policy fabric type	Allowed operations	Prohibited operations
Master (fabric set as the global policy master)	<ul style="list-style-type: none"> Create Modify Export View Tagging 	<ul style="list-style-type: none"> Import
Member	<ul style="list-style-type: none"> Import Export View Tagging 	<ul style="list-style-type: none"> Create Modify

3 – Propagate Security Policies

Once you create security policies on the global policy master, the policy metadata is automatically mirrored on to the other fabrics that are members of the global namespace.

Data Movement Considerations

The policy server in each security-policy fabric manages security policies and composite IDs. A composite ID is a unique, internal integer that maps to a security policy or set of security policies. The policy server stores the mapping in an internal volume named `mapr.pbs.composite`.

When you assign a security policy to a filesystem resource, the composite ID for that security policy is stored with the resource. Storing the composite ID with the resource instead of the security policy itself optimizes storage. For example, if a policy named HIPAA maps to composite ID 200, this composite ID is stored with any file you tag with HIPAA.

Security policies are shared across the security policy domain, but composite IDs are not. The same security policy on fabricA will have a different composite ID on fabricB and fabricC, as shown in the following table:

Fabric Name	Security Policy	Fabric ID
fabricA	HIPAA	200
fabricB	HIPAA	500
fabricC	HIPAA	800

By default, up to one million composite IDs can be created instantly after which there is a throttle process in place. The default limit of one million composite IDs is sufficient for about one thousand security policies. Using security policies as intended should not trigger the throttle process. However, using security policies for general tagging purposes can quickly exhaust composite IDs and trigger throttling.

Important Notes About Composite IDs

- You cannot see or interact with composite IDs. However, if you copy a file from one fabric to another, only the data is copied. The policy server on the destination fabric does not recognize the composite ID associated with the file and therefore cannot enforce the access controls configured in the policy. To avoid this issue, use mirroring to synchronize data. During mirroring, security policies are propagated to the destination fabric. The policy server on the destination fabric assigns new composite IDs to the security policies before data synchronization starts. The composite ID/security policy mappings are present when data synchronizes.
- Do not schedule mirroring for the composite ID internal volume `mapr.pbs.composite`.
- Composite IDs are only used with filesystem resources. The database stores policies as an array of policy IDs in the key-value store. The database policy IDs are unique across the global policy domain, which simplifies table replication. For example, policy IDs in JSON tables can be copied from one fabric to another. The server deals with the policy ID, not the policy name. Policy IDs are evaluated and translated to the policy name on the client side.

Security Policy Enforcement Process

Describes the steps followed during security policy enforcement on volumes.

Order of Enforcement

Data Fabric File System enforce security policies hierarchically, starting at the volume level.

If the volume-level enforcement mode is set to `PolicyAceAndDataAce` (default setting), the system evaluates and enforces the ACEs directly applied to data objects AND the ACEs defined in the security policies applied to data objects. When a user submits a data-operation request, the system evaluates and enforces the ACEs hierarchically, starting with the volume in which the data resides.

For example, to perform a write operation on a file, the system first evaluates permissions on the volume in which the file resides. If at least one security policy is applied to the volume, the system evaluates the ACEs set in the security policy AND the ACEs or POSIX mode bits directly applied to the volume. Both sets of ACEs must allow the user to access the volume. If one set of ACEs does not permit access to

the volume, the system denies the user permission to perform the operation. If both sets of ACEs permit access to the volume, the system checks access permissions on the file. The system evaluates security policies applied to the file AND any ACEs or POSIX mode bits applied directly to the file. Both sets of ACEs must permit the user write access on the file. If they both allow access (`writefileeace`), the user can perform the data operation on the file. If not, the system denies access.

Note the following behaviors related to the enforcement mode setting:

- When set to `PolicyAceOnly`, the system only enforces the ACEs set in security policies. A user can only perform data operations on a data object if the security policies associated with the data object allow the user access. However, if a data object is not associated with at least one security policy, the system enforces any ACEs or POSIX mode bits set directly on the data object. In this case, a user can only access the data object if the ACEs or POSIX mode bits set directly on the data object allow the user access.
- In `PolicyAceOnly` and `PolicyAceAndDataAce` modes, if a security policy is applied to a data object, and ACEs are not defined in the policy (""), the system continues to the next level data object to evaluate permissions.

Data Fabric File System Enforcement Process

The Data Fabric filesystem enforces security policies on data objects, in the following order:

- Volumes
- Files/Directories

NOTE: The system only enforces directory ACEs when determining access to the directory during directory operations. For read and write operations, directory ACEs are enforced during the path-walk operation when opening a file. If the user has a handle (FID) to the file, the user can access the file directly with the FID. In that case, the system ignores directory ACEs. See for details on directory ACEs.

The following diagram shows the order in which the Data Fabric filesystem evaluates and enforces data operations on data objects when the enforcement mode is set to `PolicyAceOnly`:

NOTE: If no policy is applied at the volume or file/directory level, the system will enforce `DataAces` (mode and ACEs applied directly on data object) to protect the data.

Indicates system evaluation and enforcement of ACEs defined in the security policies applied to data objects

Indicates system evaluation and enforcement of ACEs defined directly on data objects

The following diagram shows the order in which the Data Fabric file system evaluates and enforces data operations on data objects when the enforcement mode is set to PolicyAceAndDataAce (default mode):

The following diagram shows the order in which the Data Fabric file system evaluates and audits data operations on data objects when the enforcement mode is set to PolicyAceAuditAndDataAce (permissive mode):

NOTE: The system does not enforce denied-access checks, but does log the information about the denied check in the audit logs.

Understanding Access Control in a Security Policy

The implications of permissions assigned to users and groups in a security policy.

The following types of access can be granted to all (Public) or specific users or groups:

Entity	Permission
Directories	<ul style="list-style-type: none"> • Read the contents of a directory. If you do not select this permission, mode bits are used to determine read access. To read the contents of a directory that is tagged with this security policy, the user must also have read permissions on the volume, the parent directory (if any), and the file. • Lookup or list the contents in a directory. If you do not select this permission, mode bits are used to determine lookup access. To lookup a file of directory that is tagged with this security policy, the user must also have read permissions on the volume and the lookup permission on the directory. • List the contents of a directory. If you do not select this permission, mode bits are used to determine directorylist access. To list the contents of a directory that is tagged with this security policy, the user must also have read permissions on the volume, and lookup permission on all directories in the path (if any). • Add a file or subdirectory. If you do not select this permission, mode bits are used to determine permissions to create files or subdirectories. To add a child to a directory that is tagged with this security policy, the user must also have write permissions on the volume and the parent directory, add child permission on the parent directory, and read and execute permissions on all directories in the path. • Delete a file or subdirectory. If you do not select this permission, mode bits are used to determine permissions to create files and/or subdirectories. To delete a child of a directory that is tagged with this security policy, the user must also have write permissions on the volume and delete child permission on the parent directory, and lookup permissions on all directories in the path. <p>For more information, see Managing File and Directory ACEs on page 2131.</p>
Files	<ul style="list-style-type: none"> • Read a file. If you do not select this permission, mode bits are used to determine read access to file. To read a file that is tagged with this security policy, the user must also have read permissions on the volume, and lookup permission on all directories in path. • Write to a file. If you do not select this permission, mode bits are used to determine read access to the file. To write to a file that is tagged with this security policy, the user must also have write permissions on the volume, and lookup permission on all directories in the path. • Execute a file. If you do not select this permission, mode bits are used to determine execute access to the file. To execute a file that is tagged with this security policy, the user must also have read permissions on the volume, and lookup permission on all directories in the path. <p>For more information, see Managing File and Directory ACEs on page 2131.</p>

Security Policy Permissions

Permissions define which administrative users can create, view, and modify security policies. Administrators set the permissions on security policies through cluster-level and security policy-level ACLs.

Permission Levels

Policy-based security supports cluster-level and policy-level permissions.

The following table describes the two permission levels:

Permission Level	Description
Cluster-level	<ul style="list-style-type: none"> Controls which administrators can create and view security policies in a cluster. Administrators with cluster-level cp permission can create security policies. Administrators with cluster-level fc permission can view all the security policies created.
Policy-level	<ul style="list-style-type: none"> Controls which administrators can view and modify security policies. Policy-level permissions are set on a per-policy basis. Permissions set on one security policy do not apply to other security policies.

Administrators with cluster-level permissions can set cluster-level and security policy-level permissions through any of the following tools:

- Data Fabric UI
- `maprcli acl set|edit` commands
- `maprcli security policy create` commands

IMPORTANT: Note these important considerations for security-policy permissions:

- On a fresh cluster install, the root user and the Data Fabric user (typically named `mapr` or `hadoop` on each node) have cp permission. On an upgraded cluster, only the Data Fabric user has cp permission.
- As the cluster owner, the Data Fabric user (typically named `mapr` or `hadoop` on each node), has overriding permission on security policies, including the administrative ACLs. The Data Fabric user can create, view, and modify security policies, regardless of the cluster-level and policy-level permission specified.
- By default, [administrator](#) on page 8498 do not have permission to create security policies. Administrators need cluster-level cp (create security policy) permission to create security policies. Administrators with cluster-level a (admin) permission can grant cp permission to themselves or other administrators.

TIP: You must designate a cluster as the global policy master before you create security policies. Setting a global policy master creates a global namespace for security policies. See [Designating a Fabric as Global Policy Master](#) on page 1243.

- Any user with a valid Data Fabric ticket can view security policy IDs and names. This allows non-administrative users to determine which security policies to apply to data objects.

Permission Codes

Cluster-level and security policy-level permission codes that are set through ACLs grant security policy access to administrators. An administrator (with cluster-level `a` (admin) and `cp` (create security policy) permissions) that creates a security policy has full control over the security policy unless they specifically grant other administrators access to the security policy through policy-level permissions.

The following sections describe the cluster-level and policy-level permission codes for security policy access:

Cluster-Level Permission Codes

The following table lists some cluster-level permission codes and how they relate to security policies.

Cluster-level permission code	Description
<code>a</code> (admin)	<ul style="list-style-type: none"> Grants administrative access to cluster ACLs. Can grant create security policy (<code>cp</code>) permission to themselves or other administrators. Cannot view or edit the details of any security policy created by other admins. Can only view the security policy ID and name. Needs security policy-level permissions to view or edit security policies created by other admins.
<code>cp</code> (create security policy)	<p> ATTENTION: Administrators need this permission to create security policies.</p> <ul style="list-style-type: none"> Administrators with <code>a</code> (admin) cluster-level permission can grant <code>cp</code> permission to themselves or other administrators. Administrators can view and edit all parts of the security policies they create, including the ACEs and permissions on the security policies. Grants the administrator that creates a security policy the following security <i>policy-level</i> permissions on the security policy: <ul style="list-style-type: none"> Full Control (<code>fc</code>) Admin (<code>a</code>) Read (<code>r</code>) Administrators who create security policies can override their access to the security policies by designating policy owners who can then manage the security policies.

Cluster-level permission code	Description
fc (full control)	<ul style="list-style-type: none"> Grants full control over the cluster and enables all cluster-level administrative options. Cannot change the cluster-level ACLs. Can view all security policies. Cannot create security policies. Cannot edit the details of any security policy unless specifically granted access to a security through policy-level permissions.

Policy-Level Permission Codes

Separate read (r) and edit (fc) permissions for policy owners allow some policy owners to view policy information while others can edit policy information. This allows most administrators to administer the system without seeing the data and also prevents some policy owners from adding their credentials to the administrative ACLs to manipulate the data access ACEs.

Policy-level permissions are set on a per-policy basis. Permissions set on one security policy do not apply to other security policies.

The following table lists the policy-level permission codes needed to perform actions on security policies.

Policy-level permission code	Description
a (admin)	<ul style="list-style-type: none"> Can view and modify permissions on the security policy. Cannot view or modify the security policy; can only view the security policy name and ID.
fc (full control)	<ul style="list-style-type: none"> Can view and edit any part of the security policy, including the data access ACEs. Cannot view or modify permissions on the security policy.
r (read)	Can view all parts of a security policy, but cannot modify any part of the security policy.

Permissions Table

The following table lists the cluster-level and policy-level permissions needed to perform specific actions on security policies:

NOTE: Administrators who create a security policy have policy-level r, a, and fc permission on the security policy.

Action	Cluster-Level	Policy-Level
Create a security policy	cp	--
View details of all security policies	fc	--
View details of a security policy	--	r
View and edit permissions on a security policy (ACLs)	--	a
View and edit the details of a security policy (ACEs, auditing, wire-level encryption)	--	fc

Designating a Fabric as Global Policy Master

Designate a fabric in the global namespace as the global policy master.

About this task

A security policy domain is a group of fabrics that share data and use the same security policies to control access to the data. A security policy domain consists of a global policy master and zero or more member fabrics that constitute a global security policy namespace. Before you can create security policies, one fabric must be set as the global policy master, and security policies must be created and managed only on the fabric that is designated as the global policy master.

The primary fabric is auto-designated as the global policy master. Hence, it is not required to explicitly designate a fabric as a global policy master.

NOTE: Every 15 minutes, the policies created on the global policy master are mirrored on the member fabrics in the same global namespace.

Creating a Security Policy

Add a security policy on the global policy master.

Prerequisites

You must have the permission to create a security policy.

About this task

Security policies can be created on a fabric that is designated as the global policy master.

See [Designating a Fabric as Global Policy Master](#) on page 1243 to designate a fabric as the global policy master.

A security policy is a common set of access permissions on the Data Fabric file system that can be assigned to users and/or groups, or to public (all users).

The following permissions can be assigned on files and directories on the Data Fabric file system.

- Read, write, execute permissions on files
- Read, lookup, add child directory, delete child directory on directories

A security policy can be assigned to volumes when tagging is allowed.

See [Administering Security Policies](#) on page 1229 for details on values for the `allow_tagging` and `access_control` fields for a security policy.

NOTE: When you allow tagging, you can assign the security policy to a volume on the fabric.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Security administration icon > **Policy management** on the left pane.
3. Click **Create new** on the **Global policies** card.
4. Enter the **Name** of the security policy.
5. Enter the **Description**.
6. Select the option for **Access Control**.
7. Toggle **Allow Tagging** to allow or disallow tagging.
8. Click **Add access permissions** to add access permissions to directories and files for selected users or groups.
9. To grant permission to all users and groups, turn on the **Public** toggle. To grant permissions to specific users or groups, turn off the **Public** toggle, and enter a comma-separated list of users or groups.
10. Select the permissions to be granted on directories and files to the specified users or groups.
11. Click **Add**.
12. Click **Create**.

Results

The security policy is created and is displayed on the **Global Policies** card for the fabric.

Related maprccli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprccli` command. The command is provided for general reference. For more information, see [maprccli Commands in This Guide](#).

- `policy create`

Viewing a Security Policy

View security policy details.

About this task

You can view security policy details on the Data Fabric UI.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Security administration icon > **Policy management** on the left pane.
3. On the **Global policies** tab, click the ellipsis seen under **Actions** for the security policy to edit.
4. Click **View details** to view the security policy details.

Results

The security policy is displayed on the Data Fabric UI.

Related maprccli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprccli` command. The command is provided for general reference. For more information, see [maprccli Commands in This Guide](#).

- `policy info`

Viewing All Security Policies

View all security policies on the Data Fabric UI.

About this task

NOTE: The **View All** button is visible when you have configured five or more security policies on the global policy master.

Use the following steps to view all security policies on the Data Fabric UI.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Security administration icon > **Policy management** on the left pane.
3. Click **View All** on the **Global policies** card.

Results

All existing security policies are displayed on the Data Fabric UI.

Related maprccli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprccli` command. The command is provided for general reference. For more information, see [maprccli Commands in This Guide](#).

- `policy list`

Editing a Security Policy

Make changes to a security policy.

Prerequisites

You must be a fabric manager to perform this operation.

About this task

You can make changes to a security policy for purposes such as deprecating or retiring the security policy, and/or changing access permissions.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Security administration icon > **Policy management** on the left pane.
3. On the **Global policies** tab, click the ellipsis under **Actions** for the security policy to edit.
4. Click **Edit policy** to make changes to the policy.
5. Make the required changes.
6. Click **Save**.

Results

The changes are saved and applied.

Related maprcli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprcli` command. The command is provided for general reference. For more information, see [maprcli Commands in This Guide](#).

- [policy modify](#)

Assigning a Security Policy to One or More Volumes**About this task**

You can assign security policy to one or more volumes associated with a fabric, via the Data Fabric UI.

Follow the steps given below to assign a security policy to one or more volumes.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Security administration icon > **Policy management** on the left pane.
3. On the **Global policies** tab, click the ellipsis under **Actions** for the security policy to assign to one or more volumes.
4. Click **Assign Policies**.
5. Select the fabric and one or more volumes to assign the policy to.
6. Click **Save**.

Results

The security policy is assigned to the selected volumes.

Related maprcli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprc li` command. The command is provided for general reference. For more information, see [maprc li Commands in This Guide](#).

- [policy attach](#)

Assigning Multiple Security Policies to One or More Volumes

Describes how to assign multiple security policies to volumes.

Prerequisites

You must be a fabric manager to perform this operation.

About this task

You can assign multiple security policies to one or more volumes associated with a fabric at one go, by using the Data Fabric UI.

Follow the steps given below to assign a security policy to one or more volumes.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Security administration icon > **Policy management** on the left pane.
3. On the **Global policies** tab, click **Assign Policies**.
4. Search for policies in the search bar and select the policies to apply to a volume or a common set of volumes.
5. Click **Select Resources**.
6. Select the fabric and one or more volumes to assign the selected policies to.
7. Click **Save**.

Results

The selected security policies are assigned to the selected volumes.

Related maprc li Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprc li` command. The command is provided for general reference. For more information, see [maprc li Commands in This Guide](#).

- [policy attach](#)

Unassigning One or More Security Policies from a Volume

Unassign a policy from a volume to which it has been previously assigned.

Prerequisites

You must be a fabric user to perform this operation.

About this task

You can unassign a security policy from a volume to which it has been assigned.

Follow the steps given below to unassign one or more security policies from a volume.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the volume to rename.
5. Click the volume name seen under **Resource Name**.
6. Go to **Settings** tab for the volume.
7. Click the edit icon for **Security Policy**.
8. On the **Edit Policy** dialog box, deselect the check boxes for the policy or policies that you wish to unassign. You can use the search bar to search for the required policy if there are multiple policies attached to the volume.
9. Click **Save**.

Results

The policy is unassigned from the volume.

Enabling a Security Policy

Describes how to enable a security policy.

Prerequisites

You must be a fabric manager to perform this operation.

About this task

You can enable a security policy that has been recently created or has been disabled in the past. Once you enable a security policy, it can be assigned to a fabric resource such as a volume.

Follow the steps given below to enable a security policy.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Security administration icon > **Policy management** on the left pane.
3. On the **Global policies** tab, click the ellipsis under **Actions** for the security policy to enable.
4. Click **Edit policy** to make changes to the policy.
5. Select **Armed** from the **Access Control** dropdown.
6. Click **Save**.

Results

The security policy is enabled. An enabled security policy can be assigned to one or more volumes.

Related maprccli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprccli` command. The command is provided for general reference. For more information, see [maprccli Commands in This Guide](#).

- `policy modify`

Disabling a Security Policy

Describes how to disable a security policy.

Prerequisites

You must be a fabric manager to perform this operation.

About this task

You can disable a security policy instead of deleting it completely from Data Fabric. When you disable a security policy, it does not apply to any volume that it has been assigned to. A disabled security policy cannot be assigned to any other volume, unless the policy is enabled again.

Follow the steps given below to disable a security policy.

Procedure

1. Log on to the Data Fabric UI.
2. Click the Security administration icon > **Policy management** on the left pane.
3. On the **Global policies** tab, click the ellipsis under **Actions** for the security policy to disable.
4. Click **Edit policy** to make changes to the policy.
5. urity policy to disable.
6. Click **Edit policy** to make changes to the policy.
7. Select **Disarmed** from the **Access Control** dropdown.
8. Click **Save**.

Results

The security policy is disabled. You can enable the security policy that has been disabled.

Related maprccli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprccli` command. The command is provided for general reference. For more information, see [maprccli Commands in This Guide](#).

- `policy modify`

Administering Bucket Policies

Describes how to manage the bucket policy associated with a bucket.

A bucket policy specifies domain users and the operations they can perform on buckets. Bucket policies override the default bucket policy inherited from the account.

TIP: A bucket policy is an access control mechanism applied to objects stored on an S3 object store associated with Data Fabric, while a security policy is an access control mechanism for data stored on Data Fabric volumes.

Typically, a fabric manager applies policies; however, given the proper permissions, domain and IAM users can also apply policies.

A bucket policy comprises the following elements:

- Effect : Allow or deny permission on a resource.
- Principal: The user, group that is allowed or denied resource access.

- **Action:** The operation on the resource that is allowed or denied.
- **Resource:** The bucket resource(s) on which the action is allowed or denied.

You can create bucket policies by using the Data Fabric UI. There are two methods:

- Create or upload JSON from a file . See [Creating a Bucket Policy using JSON](#) on page 1250
- Use the policy generator to construct a JSON. See [Creating a Bucket Policy using Policy Generator](#) on page 1252

Creating a Bucket Policy using JSON

Describes how to create a bucket policy that is applicable to all objects present in the bucket.

About this task

You can add a bucket policy by using the Data Fabric UI.

If you are well-versed with JSON, you can directly write a policy JSON or upload the policy JSON from a file to create a bucket policy.

If you are not well-versed with JSON, you can use the policy generator that will generate the policy in JSON format. See [Creating a Bucket Policy using Policy Generator](#) on page 1252.

Follow the steps given below to create a bucket policy by directly uploading a JSON file or creating a JSON file.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the bucket for which you wish to create a bucket policy.
5. Click the bucket name seen under **Resource Name**.
6. Navigate to the **Settings** tab.
7. Under **Properties**, click the pencil icon for **Policy**.
8. Scroll down to view **Select File** under the blank text area.
9. Click **Select File** and select a pre-defined JSON file from the path where it is stored.
10. Click **Upload JSON**. The policy is visible in the blank text area or form visible on the **Generate Policy** page. Alternatively, you can also type in a JSON in the blank text area provided on the **Generate Policy** page.
11. Click **Save Policy**.

Results

The bucket policy is saved and applied to the bucket resources mentioned in the bucket policy. See [Sample Bucket Policy](#) on page 1251 for bucket policy JSON examples.

Related maprcli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprc li` command. The command is provided for general reference. For more information, see [maprc li Commands in This Guide](#).

- `mc policy set`

Sample Bucket Policy

Example for bucket policy.

The following bucket policy allows all users in *group1* to get, put, and delete objects, and list the bucket contents. The `${bucket}` keyword is a placeholder that the system automatically replaces with the bucket name.

```
{
  "Version": "2012-10-17",
  "Id": "PolicyContent1",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": "arn:primary:default:group:group1",
      "Action": ["s3:GetObject", "s3:PutObject", "s3:DeleteObject"],
      "Resource": "arn:aws:s3:::${bucket}/*"
    },
    {
      "Effect": "Allow",
      "Principal": "arn:primary:default:group:group1",
      "Action": ["s3:ListBucket"],
      "Resource": "arn:aws:s3:::${bucket}"
    }
  ]
}
```

The following policy allows all users in *group1* to get, put, and delete objects, and list the bucket contents while also denying *user1* and *user2* in *qagroup1* permission to perform get, put, and delete operations.

```
{
  "Version": "2012-10-17",
  "Id": "PolicyContent1",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": "arn:primary:default:group:group1",
      "Action": ["s3:GetObject", "s3:PutObject", "s3:DeleteObject"],
      "Resource": "arn:aws:s3:::${bucket}/*"
    },
    {
      "Effect": "Deny",
      "Principal": {
        "AWS": [
          "arn:primary:default:user:user1",
          "arn:primary:default:user:user2"
        ]
      },
      "Action": ["s3:GetObject", "s3:PutObject", "s3:DeleteObject"],
      "Resource": "arn:aws:s3:::${bucket}/*"
    },
    {
      "Effect": "Allow",
      "Principal": "arn:primary:default:group:group1",
      "Action": ["s3:ListBucket"],
      "Resource": "arn:aws:s3:::${bucket}"
    }
  ]
}
```

```
    ]
  }
}
```

The following policy allows *user1* to perform all the specified operations:

```
{
  "ID": "PolicyContent1",
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": "arn:primary:default:user:user1",
      "Action": [
        "s3:GetObjectRetention",
        "s3:GetObjectTagging",
        "s3:DeleteObjectTagging",
        "s3:DeleteObjectVersionTagging",
        "s3:GetObject",
        "s3:GetObjectLegalHold",
        "s3:PutObject",
        "s3:PutObjectLegalHold",
        "s3:PutObjectRetention",
        "s3:PutObjectTagging",
        "s3:DeleteObject"
      ],
      "Resource": "arn:aws:s3:::${bucket}/*"
    },
    {
      "Effect": "Allow",
      "Principal": "arn:primary:default:user:user1",
      "Action": [
        "s3:DeleteBucket",
        "s3:DeleteBucketPolicy",
        "s3:GetBucketPolicy",
        "s3:GetBucketTagging",
        "s3:ListBucket",
        "s3:PutBucketPolicy",
        "s3:PutBucketTagging"
      ],
      "Resource": "arn:aws:s3:::${bucket}"
    }
  ]
}
```

Creating a Bucket Policy using Policy Generator

Describes how to create bucket policy using policy generator.

About this task

You can add multiple statements to the policy. On saving the policy, a JSON is constructed by the policy generator.

Follow the steps given below to create a bucket policy by using the policy generator.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.

4. In the tabular list of fabrics, click the down arrow for the fabric that contains the bucket for which you wish to create a bucket policy.
5. Click the bucket name seen under **Resource Name**.
6. Navigate to the **Settings** tab.
7. Under **Properties**, click the pencil icon for **Policy**.
8. Click **Switch to form**.
9. Enter the policy name.
10. Select the **Effect**.
11. Select the **Actions** that are allowed or denied to the resource.
12. Enter the users or groups separated by commas in **Principal(s)**.
13. Enter one or more bucket names separated by commas in **Resource(s)**.
14. You can add multiple such statements by clicking the **Add** seen on the right of **Statements**.
15. Once you are done adding the statements, you can **Review policy** to review the auto-generated JSON.
16. Make changes to the JSON, if required. This is an optional step.
17. Click **Save Policy**.

Results

The bucket policy is saved. See [Sample Bucket Policy using Policy Builder](#) on page 1253 for an example.

Related maprccli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprccli` command. The command is provided for general reference. For more information, see [maprccli Commands in This Guide](#).

- `mc policy set`

Sample Bucket Policy using Policy Builder

Sample bucket policy created using policy builder.

        ]
      },
      "Action": [
        "s3:CreateBucket",
        "s3>DeleteBucket",
        "s3>DeleteBucketPolicy",
        "s3>DeleteObject",
        "s3>DeleteObjectTagging"
      ],
      "Resource": [
        "arn:aws:s3:::${bucket}/*"
      ],
      "Effect": "Allow"
    }
  ]
}
```

```

    },
    {
      "Sid": "Statement1713337230508",
      "Principal": {
        "AWS": [
          "arn:primary:default:group:group1"
        ]
      },
      "Action": [
        "s3:AbortMultipartUpload"
      ],
      "Resource": [
        "arn:aws:s3:::${bucket}/*"
      ],
      "Effect": "Deny"
    }
  ]
}

```

The aforementioned bucket policy allows all users in *group1* to create bucket, delete bucket, delete bucket policy, delete objects in the bucket, and delete objects, and delete object tagging. The policy disallows or denies permission to abort a multi-part upload of file to the bucket. The `${bucket}` keyword is a placeholder that the system automatically replaces with the bucket name.

Editing a Bucket Policy

Describes how to make changes to the bucket policy associated with a bucket.

About this task

You can edit a bucket policy.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the bucket for which you wish to revise the bucket policy.
5. Click the bucket name seen under **Resource Name**.
6. Navigate to the **Settings** tab.
7. Under **Properties**, click the pencil icon for **Policy**.
8. Continue to edit the JSON or select a JSON file from the desired location. Alternatively, click **Switch to form** to use the policy generator.
9. Make the required changes and review the policy.
10. Click **Save Policy**.

Results

The changes to the bucket policy are saved and applied to the bucket resources mentioned in the bucket policy.

Delete a Bucket Policy from a Bucket

Describes how to delete a bucket policy from a bucket.

About this task

You can delete a bucket policy by using the Data Fabric UI.

Follow the steps given below to delete a bucket policy.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of fabrics, click the down arrow for the fabric that contains the bucket for which you wish to delete the bucket policy.
5. Click the bucket name seen under **Resource Name**.
6. Navigate to the **Settings** tab.
7. Under **Properties**, click the bin icon for **Policy**.
8. Click **Delete** when asked to confirm the deletion operation.

Results

The bucket policy is deleted from the bucket.

Working with an External NFS Server

Associate an external NFS server with Data Fabric to share data across clusters in the global namespace.

NOTE: NFSv4 refers to NFS version 4.1.

An external NFSv4 server can be used to share data across clusters in the global namespace.

You can import an external NFSv4 server into Data Fabric global namespace, for a NFSv4 client to be able to access the data present on such external NFSv4 server.

See [Third-Party Storage Solutions](#) on page 7765 for details about the third-party storage solution compatibility with HPE Data Fabric.

Importing an External Network File System Server

Import an external NFS server into Data Fabric to be able to transfer data from Data Fabric to the external NFS server to make it shareable across the clusters in the global namespace or cluster group.

About this task

NOTE: NFSv4 refers to NFS version 4.1.

You can import an external network file system (NFS) into the global namespace so that the external NFS server is available and accessible to all the clusters in the global namespace.

After you import an external NFS server, you are able to transfer data from the Data Fabric cluster on to the external NFS server. The data, thus, transferred is shareable between all clusters present in the global namespace.

NOTE: NFSv4 compliant servers can be imported into Data Fabric.

See [Third-Party Storage Solutions](#) on page 7765 for details about the third-party storage solution compatibility with HPE Data Fabric.

When you are importing an external NFS server, you can specify one or more hostnames or IP addresses that are assigned to the NFS server. If multiple network interface controllers are attached to the NFS server, the NFS server is identified by multiple IP addresses or hostnames.

Follow the steps given below to import an external NFS server into Data Fabric.

Procedure

1. Log on to the Data Fabric UI .
2. Click the All resources icon on the left pane.
3. Click the **Actions** dropdown.
4. Click **Import External NFS**.
5. Enter the name for the NFS server in **NFS name**.
6. Enter the IP addresses or the hostnames for the external NFS server as a comma-separated string in **IP address or hostname**.
7. Click **Import**.

Results

The NFS server is imported into Data Fabric. The NFS server is visible under the list of resources in the global namespace.

You are able to transfer data to the NFS server after importing the NFS server.

Related maprccli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprccli` command.

- `clustergroup addexternal`

Viewing the IP Address/Hostname for External NFS Server

View the IP address or hostname associated with an external NFS server on the Data Fabric UI.

About this task

You can view the IP addresses or hostnames that are associated with an external NFS server.

Follow the steps given below to view the list of IP address(es) or hostname(s) associated with an external NFS server.

Procedure

1. Log on to the Data Fabric UI .
2. Click the All resources icon on the left pane, click the table view icon.
3. Select the **Resource details** check box.
4. In the tabular list of resources, click the ellipsis under **Actions** for the external NFS server.

5. Click the **View IP Addresses/hostnames** option under **Action**.

Results

The IP addresses or hostnames associated with the external NFS server are displayed.

Deleting an External NFS Server

Delete an external NFS server association with Data Fabric.

About this task

You can delete the association of an external NFS server with Data Fabric by using the Data Fabric UI.

Follow the steps given below to delete an external NFS server from Data Fabric.

Procedure

1. Log on to the Data Fabric UI .
2. Click the All resources icon on the left pane, click the table view icon.
3. On the Table view, click the icon under **Action** for the external NFS server.
4. Click the **Delete** option under **Action**.
5. Click **Delete** on the confirmation message that appears, to confirm deletion.

Results

The external NFS server entry is deleted from the Data Fabric UI, and the association between the external NFS server and Data Fabric is removed. You are unable to access or transfer data on the external NFS server via Data Fabric.

NOTE: If you wish to access the data on the deleted NFS server, you must import the NFS server into Data Fabric again.

Related maprcli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprcli` command. The command is provided for general reference. For more information, see [maprcli Commands in This Guide](#).

- `clustergroup remove cluster`

Working with an External S3 Object Store

A fabric manager and fabric user can import an external S3 object store into the Data Fabric UI.

NOTE: See [S3 Federation in Global Namespace](#) on page 1104 for information on federation of S3 resources in Data Fabric.

You can import a third-party S3 object store into the global namespace, to be able to view data from the third-party S3 object store, by using the Data Fabric UI. Data Fabric supports import of Amazon S3, GCP, VAST, Scalify, WEKA, and other such S3-compliant object stores.

See [Third-Party Storage Solutions](#) on page 7765 for details about the third-party storage solution compatibility with HPE Data Fabric.

To copy data from fabrics on the global namespace to the external S3 object store, download the data to a local folder and then upload to the external S3 object store.

Importing an External S3 Object Store

Describes how to import an external S3 object store into the global namespace.

Prerequisites

You must be a fabric manager to perform this operation.

If Data Fabric accesses the internet via a proxy server, do the following.

1. Specify the proxy settings in `/opt/mapr/initscripts/mapr-s3server`:

```
export HTTPS_PROXY="http://<proxy server FQDN or proxy server IP>:8080"
export http_proxy="http://<proxy server FQDN or proxy server IP>:8080"
export HTTP_PROXY="http://<proxy server FQDN or proxy server IP>:8080"
export https_proxy="http://<proxy server FQDN or proxy server IP>:8080"
```

2. Run the following command to restart the related Data Fabric component:

```
maprcli node services -name s3server -action restart -nodes $
(hostname -f) -json
```

The Data Fabric is now able to access the internet via the proxy, and able to connect to an external S3 object store.

About this task

You can import an external S3 object store into the global namespace to transfer data from the Data Fabric to the external S3 object store. You can import HPE Alletra Storage MP X10000, AWS S3, Google Cloud Platform (GCP), WEKA, Scalify, VAST and other S3-compliant object stores into a global namespace to consolidate your data across external S3 object stores on Data Fabric.

NOTE: HPE Alletra Storage MP X10000 is an intelligent, enterprise-grade, scale-out object storage to accelerate data-intensive applications. HPE Storage MP X10000 I combines automated metadata enrichment services, high-performance all-flash object storage, massive capacity, and effortless management. The X10000 accelerates time to value for your data-intensive initiatives, whether you are building active data lakes for analytics, implementing generative AI and large language models (LLMs), or enabling rapid restore from backups. See [HPE Support Center for Alletra MP X10000](#) or [HPE Alletra MP X10000 Quick Specifications](#) for more details.

See [Third-Party Storage Solutions](#) on page 7765 for details about the third-party storage solution compatibility with HPE Data Fabric.

Use the following steps to import an external S3 object store into the global namespace by using the Data Fabric UI.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left pane.
3. Click the **Actions** dropdown.
4. Click **Import External S3**.
5. Enter the name for the S3 object store in **Name**.
6. Enter the **S3 vendor type**, selecting from one of these values:
 - **HPE Alletra Storage MP X10000**
 - **AWS**

- **GCP**
- **Generic** (for WEKA, Scality, VAST, and other S3-compliant object stores)

7. Depending on the vendor type you selected, fill in the remaining values by consulting the following tables. An asterisk (*) indicates a required field:

- For **HPE Alletra Storage MP X10000**:

Parameter	Description
Name*	Name of the S3 object store.
S3 vendor	Choose HPE Alletra Storage MP X10000 .
Access key*	The access key that enables access to HPE Alletra Storage MP X10000 object storage resources for all fabrics in the global namespace.
Secret key*	The secret key that enables access to HPE Alletra Storage MP X10000 object storage resources for all fabrics in the global namespace.
Hostname / IP Address*	Enter the host names or IP addresses of the HPE Alletra Storage MP X10000 object storage as a comma-separated list.
S3 server port	The port on which HPE Alletra Storage MP X10000 object storage listens to requests. The default value is 9000.
Use TLS encryption	TLS encryption enables communication over a secure connection. TLS is enabled by default.
S3 server certificate	If the HPE Alletra Storage MP X10000 object storage is CA certified, the certificate is not required. If the HPE Alletra Storage MP X10000 object storage is not CA certified, you must drag and drop the S3 server certificate into this box to enable secure communication.

- For **AWS**:

Parameter	Description
Name*	Name of the S3 object store.
S3 Vendor	Choose AWS .
Region*	The AWS region.
Access type	For the AWS vendor type, you can select from one of the following: <ul style="list-style-type: none"> • Access Credentials • Secure Token Service
Access Credentials	Selecting this value requires you to specify an access key and secret for access to the S3 object store. See the descriptions of these keys later in this table.
Secure Token Service	Selecting this value requires you to specify a Web identity role ARN. To configure the ARN, see Configuring STS for Data Fabric on page 1266. STS is an access method that provides an alternative to the traditional access key and secret key. For more information, see Integrating the AWS Security Token Service (STS) with Data Fabric on page 1265
Access key*	A long-term credential for an Amazon user. The key enables access to S3 resources for all fabrics in the global namespace. For more information, see Managing access keys for IAM users in the Amazon documentation.
Secret key*	A long-term credential for an Amazon user. The key enables access to S3 resources for all fabrics in the global namespace. For more information, see Managing access keys for IAM users in the Amazon documentation.

Parameter	Description
Web identity role ARN*	An Amazon resource name (ARN) that enables STS authentication. See Configuring STS for Data Fabric on page 1266.

- For **GCP**:

Parameter	Description
Name*	Name of the S3 object store.
S3 vendor	Choose GCP .
Region*	The GCP region.
Access key*	A key that enables access to S3 resources for all fabrics in the global namespace.
Secret key*	A key that enables access to S3 resources for all fabrics in the global namespace.

- For **Generic**:

Parameter	Description
Name*	Name of the S3 object store.
S3 vendor	Choose Generic .
Access key*	A key that enables access to S3 resources for all fabrics in the global namespace.
Secret key*	A key that enables access to S3 resources for all fabrics in the global namespace.
Hostname / IP Address*	Enter the host names or IP addresses of the external S3 object store as a comma-separated list.
S3 server port	The server port. The default value is 9000.
Use TLS encryption	TLS encryption enables communication over a secure connection. TLS is enabled by default.
S3 server certificate	If the object storage is not CA certified, you must drag and drop the S3 server certificate into this box to enable secure communication. If the S3 server is CA certified, the certificate is not required.

8. Click **Import**.

Results

The S3 object store is imported into your global namespace, and is visible as part of the global namespace. The S3 object store is visible under the list of resources in the global namespace or list of resources with your username as the owner.

Related maprccli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprccli` command.

- `clustergroup addexternal`

Viewing Object Store Details

Describes how to view the S3 object store details such as the name, S3 vendor and other details on the Data Fabric UI.

About this task

By using the Data Fabric UI, you can view the S3 vendor, name, region and other details for an external Amazon S3, GCP or a generic object store that has been imported into the global namespace.

Procedure

1. Log on to the Data Fabric UI .
2. Click the All resources icon on the left panel, click the Table view icon.
3. On the Table View, click the ellipsis under **Actions** for the external S3 server.
4. Click the **Quick view** option.

Results

The external S3 details are displayed. The owner is the username for the user that imported the external S3 object store.

Sharing External S3 Object Store with User or Group

Describes how to share S3 object store with other users and groups by using the Data Fabric UI.

Prerequisites

You must be one of the following users to perform this operation:

- owner of the imported external S3 object store
- fabric manager

About this task

You can share an imported external object store with other Data Fabric users and groups, so that the users or groups are able to use the data from the external object store.

As a fabric manager or a fabric user, you can share the external S3 object store that has been imported by you into Data Fabric.

Follow the steps given below to share an external S3 object store with other Data Fabric users and/or into Data Fabric.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left panel, click the Table view icon.
3. On the table view, click the ellipsis under **Actions** for the external S3 server row.
4. Click **Share**.
5. Search and click on the users and/or groups with which you wish to share the external S3 object store.
6. Click **Submit**.

Results

The S3 object store is shared with the selected users and/or groups. The users and/or groups are able to access the data stored on the S3 object store.

Removing Share for External S3 Object Store

Describes how to remove sharing for an external S3 object store with other users and/or groups, by using the Data Fabric UI.

Prerequisites

You must be one of the following users to perform this operation:

- the owner of the external S3 object store
- fabric manager

About this task

As a fabric manager or a fabric user, you can share the external S3 object store that you have imported into Data Fabric.

Follow the steps given below to remove the share on an external S3 object store with other Data Fabric users and/or groups.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left panel, click the Table view icon.
3. On the table view, click the ellipsis under **Actions** for the external S3 server row.
4. Click **Share**.
5. Click the bin icon to remove sharing for the users and/or groups that you wish to stop sharing the external S3 object store with.
6. Click **Submit**.

Results

The S3 object store share is revoked for the users and/or groups that have been removed. The users and/or groups are unable to access the data stored on the S3 object store.

Deleting an External S3 Object Store

Delete reference to an external S3 object store that has been imported into the global namespace.

Prerequisites

You must be a fabric manager or a fabric user to perform this operation.

If you are a fabric user, you can delete an external S3 object store if you are the owner of the imported S3 object store.

About this task

As a fabric manager, you can remove the reference to an external S3 object store from the global namespace. Once an imported external S3 object store is deleted, you are unable to access any objects that are present on the external S3 object store. The objects, however, are not deleted from the object store. Only the object store association with the Data Fabric global namespace is removed.

A fabric user that is the owner of an external S3 object store can delete the external S3 object store from the global namespace.

Procedure

1. Log on to the Data Fabric UI.
2. Click the All resources icon on the left panel, click the Table view icon.
3. On the table view, click the ellipsis under **Actions** for the external S3 server row.
4. Click the **Delete** option.
5. Confirm the deletion of the external S3 object store.

Results

The external S3 object store is removed from the global namespace and the buckets and objects present on the external S3 server are no longer accessible from the global namespace. You are unable to manage the external S3 object store data by using Data Fabric.

Related maprcli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprcli` command. The command is provided for general reference. For more information, see [maprcli Commands in This Guide](#).

- `clustergroup remove cluster`

Integrating the AWS Security Token Service (STS) with Data Fabric

Describes how the Data Fabric can access AWS services by using the Security Token Service (STS) rather than a secret key and access key.

Data Fabric releases 7.5 and later support importing an external S3 object store into the global namespace. This feature requires the user to provide an access key and secret key to access the external S3 object store.

With release 7.7.0, Data Fabric provides an option for gaining access to AWS S3 object stores. You can import an external AWS S3 server by using the `maprcli clustergroup addexternal` command and specifying an Amazon Resource Name (ARN) to enable STS authentication. For configuration steps, see [Configuring STS for Data Fabric](#) on page 1266

With release 7.8.0, you can use the Data Fabric UI to enable STS authentication and specify the ARN when you import the external S3 object store. See [Importing an External S3 Object Store](#) on page 1259.

Using STS simplifies the process of accessing AWS services by using STS tokens for authentication. With STS tokens, the Data Fabric user can assume an AWS role and get temporary credentials to perform S3 actions. Once the external S3 object store is imported into the global namespace, **all S3 operations** automatically use STS.

How STS Works with Keycloak and Data Fabric

The following diagram illustrates the authentication flow based on a Keycloak web identity to a user account using AWS STS:

In the diagram:

1. The user logs in to the Data Fabric.
2. Keycloak authenticates the user and generates a JWT token for the user.
3. The Data Fabric requests a temporary access key and secret key for the user using the Keycloak JWT token from STS.
4. STS verifies the token validity.
5. If the token is valid, STS responds with temporary credentials to access the user's AWS account.
6. Data Fabric accesses the user account to perform the infrastructure or S3 actions.

Limitations for STS Support

Note the following limitations for using STS in the current release:

- The option to use STS when importing an S3 object store is available only for AWS S3 object stores. Non-AWS S3 object stores may not use STS with Data Fabric.
- Enabling STS requires Keycloak to be deployed on a public network IP address so that AWS STS can communicate with Keycloak and verify that the JWT tokens are from the Data Fabric software. If your Keycloak deployment resides on an intranet and is not reachable by a public network, you cannot use STS. However, you can still use the access key and secret key import method.

Configuring STS for Data Fabric

Describes how to configure the AWS role and enable STS when you import an external S3 object store into the global namespace of the HPE Data Fabric.

Enabling STS is a two-step process:

1. Configure the role in your AWS environment. See [Configuring a Role for Data Fabric in AWS](#) on page 1267.
2. Use one of the following procedures to import the external AWS S3 object store:

- Command line procedure: [Importing the External AWS S3 Object Store by Using the mapcli Command](#) on page 1271
- Data Fabric UI procedure: [Importing an External S3 Object Store](#) on page 1259

Prerequisite for Configuring STS

Enabling STS requires Keycloak to be deployed on a public network IP address so that AWS STS can communicate with Keycloak and verify that the JWT tokens are from the Data Fabric software. If your Keycloak deployment resides on an intranet and is not reachable by a public network, you cannot use STS. However, you can still use the access key and secret key import method.

For other STS limitations, see [Integrating the AWS Security Token Service \(STS\) with Data Fabric](#) on page 1265.

Configuring a Role for Data Fabric in AWS

Before importing an external S3 object store into the global namespace, you must configure your AWS environment as follows. In AWS:

1. Navigate to the Identity and Access Management (IAM) dashboard:

2. In the left-navigation pane, click **Identity providers**.
3. Click **Add provider**.
4. Click **OpenID Connect**:

aws Services Search [Alt+S]

IAM > Identity providers > Create Identity Provider

Add an Identity provider [Info](#)

Configure provider

Provider type [Info](#)

☐ SAML
Establish trust between your AWS account and a SAML 2.0 compatible Identity Provider such as Shibboleth or Active Directory Federation Services.

☒ **OpenID Connect**
Establish trust between your AWS account and Identity Provider services, such as Google or Salesforce.

Provider URL
Specify the secure OpenID Connect URL for authentication requests.
 [Get thumbprint](#)
 Maximum 255 characters. URL must begin with "https"

Audience [Info](#)
Specify the client ID issued by the Identity provider for your app.

 Maximum 255 characters. Use alphanumeric or "_.-/" characters.

This screen enables you to create an external identity provider and specify the type as OIDC.

5. Specify the provider URL:

aws Services Search [Option+S]

IAM > Identity providers > Create Identity Provider

Add an Identity provider [Info](#)

Configure provider

Provider type [Info](#)

☐ SAML
Establish trust between your AWS account and a SAML 2.0 compatible Identity Provider such as Shibboleth or Active Directory Federation Services.

☒ **OpenID Connect**
Establish trust between your AWS account and Identity Provider services, such as Google or Salesforce.

Provider URL
Specify the secure OpenID Connect URL for authentication requests.

 Maximum 255 characters. URL must begin with "https"

Audience [Info](#)
Specify the client ID issued by the Identity provider for your app.

 Maximum 255 characters. Use alphanumeric or "_.-/" characters.

Add tags - optional [Info](#)

Tags are key-value pairs that you can add to AWS resources to help identify, organize, or search for resources.

No tags associated with the resource.

[Add new tag](#)
You can add up to 50 more tags.

[Cancel](#) [Add provider](#)

You can obtain this URL from the SSO setup card of the Data Fabric UI:

6. Set the **Audience** field to **edf-client**, and click **Add provider**. The new provider is added to the list of providers on the **Identity providers** page.
7. In the left-navigation pane, click **Roles** to create a role.
8. For the trusted entity type, click **Web identity**:

9. Select the identity provider that you created in the previous step, then verify that the **Audience** is **edf-client**.
10. Click **Next**.

11. Add the permission policies that are applicable for this role. Any entity assuming this role will have these permissions. Specify **AmazonS3FullAccess**:

12. Click **Next**.
13. Provide a name for the role. For example:

14. Scroll down, and click **Create role**.
15. Navigate to the newly created role to get its **ARN**. Note the **ARN** string:

You must provide the **ARN** in the next set of steps when you use the `maprc li` command to import AWS S3 into the global namespace by using STS.

Importing the External AWS S3 Object Store by Using the `maprc li` Command

Starting with release 7.7.0, the `maprc li cluster group addexternal` command is enhanced with a new option to support STS-based access. The command, which is used to import external S3 servers, includes a new `-awswebidrolearn` option. To enable STS when you run the command, you must:

- Specify the `-awswebidrolearn` option
- Set the `-type` option to `s3`
- Set the `-s3vendor` option to `aws`

When you use these settings, Data Fabric ignores the provided access key and secret key and ensures that S3 access for the server is achieved through STS using the specified `-awswebidrolearn`.

The following example command configures an external S3 object store to use STS access:

```
maprc li cluster group addexternal -type s3 -s3vendor aws -awswebidrolearn
'arn:aws:iam::74601xxxxxxx:role/Keycloak-webid-s3-readonly'
```

Related `maprc li` Commands

To implement the features described on this page, Data Fabric relies on the following `maprc li` command. A link to this command is provided for general reference. For more information, see [maprc li Commands in This Guide](#).

- `cluster group addexternal`

Administering Alarms

Manage alarms via the Data Fabric.

About this task

Alarms are the alerts or notifications generated by Data Fabric.

Alarms could be alerts related to errors, warnings, or information related to various fabric resources.

Following are the types of alarms are generated by Data Fabric.

- Fabric alarms
- User alarms
- Node alarms
- Volume alarms

Alarms raised by Data Fabric can be viewed, muted, or dismissed from the Data Fabric UI.

See [Viewing Alarms](#) on page 1272 for the procedure to view alarms on the Data Fabric UI

See [Muting/Dismissing Alarms](#) on page 1272 to mute an alarm or dismiss an alarm via the Data Fabric UI.

Viewing Alarms

View alarms on the [Data Fabric UI](#) on page 1100.

Prerequisites

You must have access to the Data Fabric UI and the permission to view alarms.

About this task

Following are the types of alarms are generated by Data Fabric.

- Fabric alarms
- User alarms
- Node alarms
- Volume alarms

Procedure

Log on to the Data Fabric UI to see a list of alarms.

Results

The list of alarms is displayed on the **Alarms** card on the right side of the Home page. Alternatively, you could click the bell icon at the top right corner next to the help icon on the Home page.

You can mute or dismiss an alarm.

Related maprcli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprcli` command. The command is provided for general reference. For more information, see [maprcli Commands in This Guide](#).

- `alarm list`

Muting/Dismissing Alarms

Mute or dismiss an alarm by using the Data Fabric UI.

Prerequisites

You must have access to Data Fabric UI and the permission to mute or dismiss an alarm.

About this task

You can mute or dismiss an alarm that is visible on the Data Fabric UI. An alarm can be muted for 24 hours, 6 hours or 1 hour.

Follow the steps given below to mute/dismiss an alarm.

Procedure

1. Log on to the Data Fabric UI.
2. Click the bell icon at the top right corner next to the help icon.
3. Click **View all** to view all alarms.
4. To mute an alarm, click **Mute** and select the duration for which you wish to mute the alarm. Alternatively, click **Dismiss** to dismiss the alarm.

Results

The alarm is muted for the specified duration or the alarm is dismissed, depending on the action you have selected.

Related maprccli Commands

To implement the features described on this page, the Data Fabric UI relies on the following `maprccli` command. The command is provided for general reference. For more information, see [maprccli Commands in This Guide](#).

- `alarm mute`

Setting Up Clients Using the Data Fabric UI

Summarizes the steps for enabling client communication with the HPE Data Fabric.

Clients allow hosts to communicate with the HPE Data Fabric. Set up clients and install client libraries to allow applications to access services on the HPE Data Fabric.

To run against the HPE Data Fabric platform, certain application types require a client and the following client libraries:

- HDFS API
- HBase API

Installing Clients on a Linux Host

Describes how to install the client on a Linux host.

Basic Steps for Client Installation

To install the Data Fabric client software on a Linux host that you want to communicate with the HPE Data Fabric:

1. Complete the steps in [Preparing to Install a Data Fabric Client](#) on page 1273 later on this page.
2. Use one of these procedures to install the client on the Linux host:
 - [Installing the Data Fabric Client on RHEL](#) on page 1283
 - [Installing the Data Fabric Client on SLES](#) on page 1283
 - [Installing the Data Fabric Client on Ubuntu](#) on page 1283
3. Perform the steps in [Installing Client Libraries](#) on page 1282 to enable your fabric to communicate with the clients.

Preparing to Install a Data Fabric Client

Before you install the Data Fabric client, perform the following steps:

1. **Verify that the operating system on the machine where you plan to install the client is supported.** For a list of operating systems that are compatible with the Data Fabric clients, see .
2. **Verify that the machine where you plan to install the client is not a fabric node.** The Data Fabric client is intended for use on a computer that has no other Data Fabric server software installed.
3. **Configure repositories for the client.** The client nodes also need to have the Data Fabric repositories configured in order to pull the client packages. See [Setting up the Data Fabric Repository](#) on page 1277.
4. **Install the Data Fabric package key.** The package key must be installed before you can install Data Fabric packages. To install the package key, issue the command appropriate for your Linux distribution:

IMPORTANT: To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see [Accessing the HPE Data Fabric Token-Authenticated Internet Repository](#) on page 1280.

- RHEL/Rocky/Oracle Enterprise Linux

```
wget --user=<email> --password=<token> -O /tmp/maprgpg.key -q https://
package.ezmeral.hpe.com/releases/pub/maprgpg.key && rpm --import /tmp/
maprgpg.key
wget --user=<email> --password=<token> -O /tmp/hpeezdf.pub -q https://
package.ezmeral.hpe.com/releases/pub/hpeezdf.pub && rpm --import /tmp/
hpeezdf.pub && gpg --import /tmp/hpeezdf.pub
```

- Ubuntu

```
wget --user=<email> --password=<token> -O /tmp/maprgpg.key -q https://
package.ezmeral.hpe.com/releases/pub/maprgpg.key && sudo apt-key
add /tmp/maprgpg.key
wget --user=<email> --password=<token> -O /tmp/gnugpg.key -q https://
package.ezmeral.hpe.com/releases/pub/gnugpg.key && sudo apt-key
add /tmp/gnugpg.key
```

For SLES only, you do not have to install the package key because zypper allows package installation with or without the key.

To install the client, obtain the Data Fabric packages for your operating system at <https://package.ezmeral.hpe.com/> and complete the installation steps described in one of the subsequent topics.

About Access and Refresh Tokens

Describes how to use the downloadable tokens provided for client access.

How Clients Use Tokens

In Data Fabric deployments where SSO is configured, you must provide an SSO user name and password for access to a fabric. Clients that aren't aware of SSO user names and passwords can gain access to RPC communications by using JSON web tokens (JWTs). A JSON Web Token (JWT) is a method for securely transmitting information between services in a computing system.

In a Data Fabric deployment, the Keycloak SSO provider can generate tokens when a user supplies an SSO user name and password. The tokens enable the creation of short-lived Data Fabric tickets that facilitate communication with the file system.

Issuing commands from any of the following command line interfaces (CLIs) or clients requires the user or client to have a valid ticket.

- `maprc li`
- `hadoop`
- `mc`
- `fuse (service start)`
- `loopback nfs (service start)`

The ticket allows the command line to connect to the CLDB service. To facilitate the process, you must obtain a token from the SSO provider and place it in a secure location that can be specified in an environment variable. Exporting the environment variable creates a temporary ticket, enabling the CLI to talk to the CLDB server. This method permits the use of any command without a password for the duration of the ticket.

For more information about Data Fabric tickets, see [Managing Tickets](#).

Downloading the Tokens

In the Data Fabric UI, you use the **Client library** command to download the tokens. The tokens are contained in the `jwt_tokens.tar.gz` file, which are extracted to the client. The `jwt_tokens.tar.gz` file contains the following token files:

Token Type	File	Function
Access	<code>jwt_access</code>	Encapsulates the user's authentication information within the fabric.
Refresh	<code>jwt_refresh</code>	Enables the creation of a new access token when the current access token expires.

For more information about downloading the tokens, see [Installing Client Libraries](#) on page 1282.

Exporting the Tokens

To enable a client to use the tokens, you must export the path to each token. This must be done each time you establish a host session. To export the paths:

Client	To export the tokens . . .
Hadoop	Use these commands: <pre>export MAPR_JWT_TOKEN_LOCATION="/root/jwt_access" export MAPR_REFRESH_TOKEN_LOCATION="/root/jwt_refresh"</pre>
Fuse POSIX	Add the export paths shown for the Hadoop client in the first row of this table to the top of the following file: <pre>/opt/mapr/initscripts/mapr-posix-client-basic</pre>
Loopback NFS	Add the export paths shown for the Hadoop client in the first row of this table to the top of the following file: <pre>/usr/local/mapr-loopbacknfs/initscripts/mapr-loopbacknfs</pre>

Alternatively, you can add the tokens to the `core-site.xml` file. Adding them to `core-site.xml` file causes the fabric to use the designated tokens *every time you log on*. To add the tokens, specify the following property in the `core-site.xml`:

```
<property>
  <name>fs.mapr.sso.tokenpath</name>
  <value>/root/jwt_access</value>
</property>
```

Token and Ticket Expiration and Renewal

Tokens and tickets expire after a short time. By default, Keycloak-generated tokens expire after two (2) hours. Short-lived tickets expire after 20 minutes.

If an access token expires or becomes invalid, the client application can use a refresh token to obtain a new access token without requiring the user to re-authenticate. The client application sends Keycloak a token-refresh request along with the current refresh token. Keycloak validates the refresh token and issues a new access token. This automatic-refresh mechanism repeats itself to allow client jobs to run for days or weeks as long as the tokens remain valid.

Changing Token and Ticket Durations

You can change the valid duration of tokens and tickets. Note that a ticket is valid for no more than 20 minutes or the expiry time of its associated access token, *whichever is lower*. Thus, if a ticket expiry time is set for 20 minutes and the associated access token is valid only for 10 minutes, the ticket will be valid for only 10 minutes.

CAUTION: Setting long lifetimes for tokens or tickets can introduce a considerable security risk. Hewlett Packard Enterprise recommends finding a balance between security and usability and, whenever possible, erring on the side of security in your use of tokens and tickets.

To check or change the expiry setting for short-lived tickets, see [Checking and Changing the Temporary Ticket Duration](#).

To change the expiration setting for a token, you must be the fabric manager and have access to the Keycloak UI.

Access Token Expiry

You can configure the access token expiry time at the realm level or at the client level.

1. Log in to the Keycloak admin console. See [Accessing the Keycloak Administration Console](#) on page 1290.
2. Select the realm for which you want to configure the access token expiry time.
3. Go to the **Realm Settings > Tokens** tab.
4. In the **Access Token Lifespan** field, specify the desired expiration time for the access tokens in hours, minutes, or days.
5. Save your changes.

Refresh Token Expiry

You typically configure the refresh token expiry time at the realm level:

1. Log in to the Keycloak admin console. See [Accessing the Keycloak Administration Console](#) on page 1290.
2. Select the realm for which you want to configure the access token expiry time.
3. Go to the **Realm Settings > Sessions** tab.
4. In the **SSO Session Max** field, specify the desired maximum lifespan for refresh tokens in minutes, hours, or days.
5. Save your changes.

Setting up the Data Fabric Repository

This section describes how to make packages available through the HPE Data Fabric repository.

The HPE Data Fabric repository on the internet provides all of the packages required to install a Data Fabric cluster using native tools such as:

- yum on RHEL
- zypper on SLES
- apt-get on Ubuntu

Installing from the internet repository is generally the easiest installation method, but requires the greatest amount of bandwidth. With this method, each node is connected to the internet to download the required packages.

Set up repositories by completing the steps for your RHEL, SLES, or Ubuntu distribution.

Adding the Data Fabric Repository on RHEL

This section describes how to install the Data Fabric repository.

Procedure

1. Change to the root user or use sudo.

2. Create a text file called `hpe-datafabric.repo` in the `/etc/yum.repos.d/` directory with the following content, replacing `<version>` with the version of Data Fabric software that you want to install:

IMPORTANT: To access the Data Fabric internet repository, you must specify the user name (email) and token of an HPE Passport account. For more information, see [Setting up the Data Fabric Repository](#) on page 1277.

```
[hpe-datafabric]
name=HPE Data Fabric
baseurl=https://package.ezmeral.hpe.com/releases/v<version>/rhel9/
username=<email-address>
password=<token>
enabled=1
gpgcheck=1
protect=1

[hpe-datafabric-ecosystem]
name=HPE Data Fabric
baseurl=https://package.ezmeral.hpe.com/releases/MEP/MEP-<version>/redhat
username=<email-address>
password=<token>
enabled=1
gpgcheck=1
protect=1
```

NOTE: For RHEL versions 8 and earlier, the hpe-datafabric repository URL ends in **/redhat**; for RHEL version 9, the hpe-datafabric repository ends in **/rhel9**. The hpe-datafabric-ecosystem repository URL for all RHEL versions, including RHEL 8 and RHEL 9, ends in **/redhat**.

3. If your connection to the Internet is through a proxy server, you must set the `http_proxy` environment variable before installation: You should also set the value for the `http_proxy` environment variable by adding the following section to the `/etc/yum.conf` file:

```
http_proxy=http://<host>:<port>
export http_proxy
```

```
proxy=http://<host>:<port>
proxy_username=<username>
proxy_password=<password>
```

Adding the Data Fabric Repository on SLES

This section describes how to install the Data Fabric repository.

Procedure

1. Change to the root user or use `sudo`.

2. Use the following command to add the repository for Data Fabric packages, replacing <version> with the version of Data Fabric software that you want to install:

IMPORTANT: For SLES distributions, if your user name is an email address that includes special characters – such as the @ symbol – you must URL encode the special characters so that the correct email address is passed to the authentication protocols in the repository. For most email addresses, changing the @ symbol to %40 is sufficient. For example:

Unencoded email address: jane.smith@company.com

URL encoded email address: jane.smith%40company.com

To encode other special characters, see "URL Encoded Emails" at [HPE Software Delivery Repository](#).

```
zypper ar https://<email>:<token>@package.ezmeral.hpe.com/releases/
v<version>/suse/ maprtch
```

3. Use the following command to add the repository for ecosystem packages:

```
zypper ar https://<email>:<token>@package.ezmeral.hpe.com/releases/MEP/
MEP-<version>/suse/ maprecosystem
```

4. If your connection to the Internet is through a proxy server, you must set the http_proxy environment variable before installation:

```
http_proxy=http://<host>:<port>
export http_proxy
```

5. Update the system package index by running the following command:

```
zypper refresh
```

6. Data Fabric packages require a compatibility package in order to install and run on SLES. Execute the following command to install the SLES compatibility package:

```
zypper install mapr-compat-suse
```

Installing sshpass

About this task

Before installing a cluster on a SLES image, you must run the following command to install sshpass:

```
zypper --non-interactive -q --no-gpg-checks -p http://download.opensuse.org/
distribution/leap/42.3/repo/oss/ install sshpass
```

Adding the Data Fabric Repository on Ubuntu

This section describes how to install the Data Fabric repository.

Procedure

1. Change to the root user or use sudo.

2. Create the following file:

```
# cat /etc/apt/auth.conf.d/package.ezmeral.hpe.com.conf
machine package.ezmeral.hpe.com
login <HPE-Passport-email>
password <HPE-Passport-token>
```

IMPORTANT: To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see [Setting up the Data Fabric Repository](#) on page 1277.

3. Add the following lines to `/etc/apt/sources.list`, replacing `<version>` with the version of Data Fabric software that you want to install:

```
deb https://package.ezmeral.hpe.com/releases/v<version>/ubuntu/ binary
bionic
deb https://package.ezmeral.hpe.com/releases/MEP/MEP-<version>/ubuntu/
binary bionic
```

4. Update the package indexes:

```
apt-get update
```

5. If your connection to the Internet is through a proxy server, add the following lines to `/etc/apt/apt.conf`:

```
Acquire
{
  Retries "0";
  HTTP
  {
    Proxy "http://<user>:<password>@<host>:<port>";
  };
};
```

Accessing the HPE Data Fabric Token-Authenticated Internet Repository

Describes special considerations for using the token-authenticated internet repository for Data Fabric software and the ecosystem components.

Accessing the Token-Authenticated Repository

Using a browser to access the new token-authenticated package repository for Data Fabric requires you to supply the email address associated with your HPE account and a token. Use these steps:

1. Navigate to the repository at <https://package.ezmeral.hpe.com/>.

The authorization dialog box is displayed:

Sign in to access this site
 Authorization required by <https://package.ezmeral.hpe.com>

Username

Password

Paste the email address for your HPE account

Paste a token

2. In the **Username** field, paste the email address for your HPE Passport account. To obtain an HPE Passport Account, see [Obtaining an HPE Passport Account](#) on page 1281.
3. In the **Password** field, paste a token. To obtain a token, see [Obtaining a Token](#) on page 1281.
4. Click **Sign in**.

Format for Passing an HPE User Name and Token to the Repository

Any files or scripts that point to the new Data Fabric internet repository must include the email address and token associated with a valid HPE account expressed in the following format:

```
https://<email-address>:<token>@package.ezmeral.hpe.com/
```

Examples for Accessing the Repository

In examples that require you to run Linux commands that point to the repository, this guide shows the format that is needed for including the user name and password. For example, to use a `wget` command with the new repository, you must add the email address and token as follows:

```
wget --user=jane.smith@company.com --password=<token> https://  
package.ezmeral.hpe.com/releases/installer/mapr-setup.sh -P /tmp
```

Depending on the Linux distribution, other formats might be needed.

Obtaining an HPE Passport Account

An HPE Passport account is required to obtain support for Data Fabric products and gives you access to important HPE services. To obtain an HPE Passport account, visit the [MY HPE SOFTWARE CENTER](#) and click **Sign In** to create a new account.

When you fill in information about your account, be sure to complete ALL of the fields (even fields that are not required). Leaving some fields blank can cause issues when you later try to access HPE repositories.

Obtaining a Token

A token associated with your HPE Passport account is required to obtain access to the HPE Ezmeral internet repositories. You can create a new token at any time by using the following steps. A token created in this way does not expire. The token remains valid even after you create a new token.

To create a token for your HPE Passport account:

1. Visit the [HPE Support Center User Token](#) page.
2. Sign in if needed using your HPE Passport user ID and password.

Enable the EPEL Repository

Note: This feature is presented as a developer preview. Developer previews are not tested for production environments, and should be used with caution.

This section describes how to download and install the EPEL repository depending on your RHEL version.

Enable the EPEL Repository on RHEL 8.x/RHEL 9.x

1. Download the EPEL repository:

```
wget http://dl.fedoraproject.org/pub/epel/  
epel-release-latest-8.noarch.rpm
```

2. Install the EPEL repository:

```
rpm -Uvh epel-release-latest-8*.rpm
```

Installing Client Libraries

Describes how to install the client libraries to enable communication between your Linux hosts and the HPE Data Fabric.

To install client libraries on a fabric:

1. Install the client packages using the steps described in [Installing Clients on a Linux Host](#) on page 1273.
2. Sign in to the Data Fabric UI.
3. Select the **Fabric user** view on the **Home** page.

4. On the **Home** page, click the ellipsis () in the **Action** column of the fabric for which you want to install the client libraries.

Alternatively, navigate to the **Fabric Details** page, open the **Actions** dropdown menu, and select **Client library**.

5. Click the **Client library** option. The **Client library** side drawer opens.
6. Download the `config.tar` and the `jwt_tokens.tar.gz` files listed in the **Client library** side drawer. These files include information needed to set up the client libraries for your fabric.
7. Copy the downloaded files to the client machine. On the client machine, perform the following steps.
8. Run the command to extract the setup:

```
tar xf config.tar --directory /opt/mapr
```

9. Run the command to extract the JWT tokens:

```
tar xf jwt_tokens.tar.gz --directory /root
```

10. Run the commands to export the JWT tokens:

```
export MAPR_JWT_TOKEN_LOCATION="/root/jwt_access"
```

```
export MAPR_REFRESH_TOKEN_LOCATION="/root/jwt_refresh"
```

11. Run the command to configure your client libraries:

```
/opt/mapr/server/configure.sh -R
```

12. Run the command to test that your client libraries are set up correctly:

```
hadoop fs -ls /
```

If the client libraries are not set up correctly, the command returns an error message.

Installing the Data Fabric Client on RHEL

This section describes how to install the Data Fabric client on Red Hat Enterprise Linux (RHEL).

These steps assume that you have already installed the package key as described in [Installing Clients on a Linux Host](#) on page 1273 and set up a Data Fabric repository as described in [Setting up the Data Fabric Repository](#) on page 1277.

1. Remove any previous Data Fabric software. You can use `rpm -qa | grep mapr` to get a list of installed Data Fabric packages, then type the packages separated by spaces after the `rpm -e` command:

```
rpm -qa | grep mapr
rpm -e mapr-fileserver mapr-core
```

2. Install the client for your target architecture:

```
yum install mapr-edf-clients
```

3. Open the Data Fabric UI to complete the configuration, as described in [Installing Client Libraries](#) on page 1282.

Installing the Data Fabric Client on SLES

This section describes how to install the Data Fabric Client on SLES.

1. Remove any previous Data Fabric software. You can use `rpm -qa | grep mapr` to get a list of installed Data Fabric packages:

```
rpm -qa | grep mapr
```

Then type the package names separated by spaces after the `zypper rm` command. For example:

```
zypper rm mapr-fileserver mapr-core
```

2. Run the following command to install the Data Fabric client:

```
zypper install mapr-edf-clients
```

3. Open the Data Fabric UI to complete the configuration, as described in [Installing Client Libraries](#) on page 1282.

Installing the Data Fabric Client on Ubuntu

This section describes how to install the Data Fabric client on Ubuntu.

1. Remove any previous Data Fabric client software. You can use `dpkg --get-selections | grep mapr` to get a list of installed Data Fabric packages. Then type the packages separated by spaces after the `dpkg -r` command. For example:

```
dpkg -r mapr-core mapr-fileserver
```

2. Update your Ubuntu repositories. For example:

```
apt-get update
```

3. Make sure the client is running JDK 11 or later:

```
$ echo $JAVA_HOME
/Library/Java/JavaVirtualMachines/jdk-11.0.1.jdk/Contents/Home
$ /Library/Java/JavaVirtualMachines/jdk-11.0.1.jdk/Contents/Home/bin/
java -version
openjdk version "11.0.1" 2018-10-16
OpenJDK Runtime Environment 18.9 (build 11.0.1+13)
OpenJDK 64-Bit Server VM 18.9 (build 11.0.1+13, mixed mode)
```

4. Run the following command to install the Data Fabric client:

```
apt-get install mapr-edf-clients
```

5. Open the Data Fabric UI to complete the configuration, as described in [Installing Client Libraries](#) on page 1282.

Reference

Provides reference information for the HPE Data Fabric.

Port Information for Seed Node Fabric

Describes the ports used by HPE Data Fabric services.

The following table lists the principal services, the ports they use, and the associated protocol. For traffic within a subnet, the port is not relevant. Hosts can communicate on any available port:

Service	Port	Protocol
CLDB	7222	TCP
Data Fabric Gateway	7660	TCP
Data Fabric Keycloak	443*	TCP
Data Fabric UI	8443	TCP
Fileserver	5660	TCP
Fileserver	5692	TCP
Installer	9443	TCP
MOSS (Multithreaded Object Store Server)	9000	TCP
NFS (into VPC UDP)	111	UDP
NFS (into VPC TCP)	2049	TCP
OpenTSDB	4242	TCP
SSH	22	TCP
Kafka Wire Protocol Service	9092	TCP

The port can be 6443 for upgraded fabrics.

Runbook: Edge Node Configuration

This section provides examples of test cases conducted in a cloud deployment to prove the replication capabilities of Data Fabric in various failure scenarios.

IMPORTANT: The runbook information is currently under development and is a post-GA deliverable.

Operating System Support Matrix for Seed Node Fabric

The tables on this page show the Linux operating-system versions that are supported for HPE Data Fabric releases.

On-premises deployments can use any of the following operating-system versions. Cloud (AWS, Azure, GCP) deployments use Rocky Linux as the default OS.

Red Hat Enterprise Linux (64-bit)

RHEL Version	Release 8.1.x	Release 8.0.x	Release 7.10.x	Release 7.9.x	Release 7.8.x	Release 7.7.x	Release 7.6.x	Release 7.5.0
9.6	Yes	Yes	No	No	No	No	No	No
9.4	Yes	Yes	Yes	Yes	Yes	No	No	No
9.0	Yes	Yes	Yes	Yes	Yes	Yes	No	No
8.10	Yes	Yes	Yes	Yes	Yes	No	No	No
8.8	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
8.6	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
8.5	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
8.4	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
8.3	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
8.2	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
8.1	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes

Rocky Linux (64-bit)

Rocky Version	Release 8.1.x	Release 8.0.x	Release 7.10.x	Release 7.9.x	Release 7.8.x	Release 7.7.x	Release 7.6.x	Release 7.5.0
9.4	Yes	Yes	Yes	Yes	Yes	No	No	No
8.5	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
8.4	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes

Ubuntu (64-bit)

Ubuntu Version	Release 8.1.x	Release 8.0.x	Release 7.10.x	Release 7.9.x	Release 7.8.x	Release 7.7.x	Release 7.6.x	Release 7.5.0
22.04	Yes ¹	Yes ¹	Yes ¹	Yes ¹	Yes ¹	Yes ¹	No	No
20.04	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
18.04	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes

¹Releases 7.x and 8.x have a dependency on the `libssl1.1` package, which is not included in Ubuntu 22.04.

To resolve this issue, you must apply the package manually to Ubuntu 22.04 nodes before installing Data Fabric software on every node in the fabric or cluster:

The following steps are required for cluster nodes but are not required for client nodes.

1. Download the libssl1.1 package:

```
wget http://archive.ubuntu.com/ubuntu/pool/main/o/openssl/libssl1.1_1.1.0g-2ubuntu4_amd64.deb
```

2. Use the following command to install the package:

```
sudo dpkg -i libssl1.1_1.1.0g-2ubuntu4_amd64.deb
```

SLES (64-bit)

SLES Version	Release 8.1.x	Release 8.0.x	Release 7.10.x	Release 7.9.x	Release 7.8.x	Release 7.7.x	Release 7.6.x	Release 7.5.0
15 SP5	Yes	Yes	Yes	Yes	Yes	No	No	No
15 SP4	Yes	Yes	Yes	Yes	Yes	No	No	No
15 SP3	No	No	Yes	Yes	Yes	Yes	Yes	Yes
15 SP2	No	No	Yes	Yes	Yes	Yes	Yes	Yes

Oracle Enterprise Linux (OEL)

OEL Version	Release 7.10.0 and later	Release 7.9.0	Release 7.8.0	Release 7.7.x	Release 7.6.x	Release 7.5.0
8.4	No	No	No	Yes	Yes	Yes
8.3	No	No	No	Yes	Yes	Yes
8.2	No	No	No	Yes	Yes	Yes

Administering Users and Clusters

Lists topics that help manage a Data Fabric cluster.

This section describes processes involved in managing a Data Fabric cluster. Topics include setting up users and groups, adding licenses to the cluster, enabling/disabling auditing of cluster administration, configuring disk and role balancers, and allocating quotas for users and groups and setting cluster reserve limit.

Managing Users and Groups

Provides a brief introduction to user management on an HPE Data Fabric cluster.

The following two users are important when installing and setting up Data Fabric software:

- `root` is used to install Data Fabric software on each node.
- The “Data Fabric user” is the user that Data Fabric services run as (typically named **mapr** or **hadoop**) on each node. The Data Fabric user has full privileges to administer the cluster. Administrative privilege with varying levels of control can be assigned to other users as well.

Before installing Data Fabric, decide on the name, user ID (UID) and group ID (GID) for the Data Fabric user. The Data Fabric user must exist on each node, and the user name, UID and primary GID must match on all nodes.

- When adding a *user* to a cluster node, specify the `--uid` option with the `useradd` command to guarantee that the user has the same UID on all machines.

- When adding a *group* to a cluster node, specify the `--gid` option with the `groupadd` command to guarantee that the group has the same GID on all machines.

Data Fabric uses the native operating system configuration of each node to authenticate users and groups for access to the cluster. If you are deploying a large cluster, you should consider configuring all nodes to use LDAP or another user management system. You can use the Control System to grant specific permissions to particular users and groups. For more information, see [Setting User Permissions](#). Each user can be restricted to a specific amount of disk usage. For more information, see [Setting Quotas for Users and Groups](#).

By default, Data Fabric grants the user `root` full administrative permissions. If the nodes do not have an explicit `root` login, grant full permissions to another user after deployment. See [Adding Cluster Permissions](#) on page 1315.

On the node where you plan to run the `mapr-apiser` (the Control System), install Pluggable Authentication Modules (PAM). See [PAM Configuration](#) for more information.

You can perform the following procedures to manage users and groups in a Data Fabric cluster using the Control System (click **Admin** > **User Settings**) and the CLI:

Setting Up Email Addresses

Describes how to set up email addresses using the Control System and the CLI.

Setting Up Email Addresses Using the Control System

About this task

To set up email addresses for cluster users, in the Control System under **Admin** > **User Settings** > **Email Address**:

Procedure

- Choose one of the following to configure the cluster to use an SMTP server to send email:
 - Use Company Domain** to specify a domain to append after each user name to complete each user's email address
 - Use LDAP** to obtain each user's email address from an LDAP server.
- Specify, for:

Use Company Domain

Domain to append after each user name to complete each user's email address in the **user @** field.

Use LDAP

LDAP Server	The LDAP server address.
LDAP Port	The LDAP server port number. You can select the Use Secured Port checkbox to use port 636.
Bind Domain	The bind domain for the users.
Bind Domain Password	The bind password for the users.
Base Domain	The base domain.
UID Attribute	The user ID.

Mail Attribute	The mail attribute.
----------------	---------------------

3. Click **Save Changes**.

Setting Up Email Addresses Using the CLI or the REST API

About this task

The basic command to set up email address for a user is:

```
maprcli entity modify -name <entityname> -type 0 -email <email>
```

For complete reference information, see [entity modify](#) on page 2481.

Setting Up SMTP

Describes how to set up SMTP information using the Control System and the CLI.

About this task

You can specify SMTP server information for the cluster using the Control System and the CLI.

Setting Up SMTP Using the Control System

About this task

Use the following procedure to configure the cluster to use an SMTP server to send email:

Procedure

- 1. Log in to the Control System and click **Admin > User Settings > SMTP**.
- 2. Set up the email account the HPE Data Fabric cluster must use to send alerts and other notifications.

Provider	Select Gmail , Office 365 , or SMTP from the drop-down menu. If you select Gmail or Office 365 , the SMTP server and port information will be pre-filled for you.
SMTP Server	The SMTP server to use for sending mail.
This server requires an encrypted connection (SSL)	Specifies an SSL connection to SMTP.
SMTP Port	The SMTP port to use for sending mail.
Sender's Full Name	The name that HPE Data Fabric should use when sending email. Example: MapR Cluster
Sender's Email Address	The email address that HPE Data Fabric should use when sending email.
Sender's Username	(Optional) The user name that HPE Data Fabric should use when logging on to the SMTP server.
Sender's SMTP Password	(Optional) The password that HPE Data Fabric should use when logging on to the SMTP server.

3. Click **Save Changes**.

An email request is sent to the specified email address. You can check the `/opt/mapr/logs/cldb.log` file if there is a problem sending the email. If there is a problem, also check the fields to make sure that the SMTP information is correct. Click **Revert** if you wish to cancel the changes.

Setting Up SMTP Using the CLI

About this task

Use the `maprcli config save` command to set the SMTP server. For example:

```
maprcli config save -values '{"mapr.smtp.provider":"gmail",
    "mapr.smtp.server":"smtp.gmail.com",
    "mapr.smtp.sslrequired":"true",
    "mapr.smtp.port":"465",
    "mapr.smtp.sender.fullname":"Ab Cd",
    "mapr.smtp.sender.email":"xxx@gmail.com",
    "mapr.smtp.sender.username":"xxx@gmail.com",
    "mapr.smtp.sender.password":"abc"}'
```

For complete reference, see [config save](#) on page 2394.

Configuring SSO

Describes how the HPE Data Fabric supports single sign-on (SSO) and how to configure it.

HPE Data Fabric releases 7.3.0 and later support SSO when configured with the Keycloak identity and access management (IAM) solution. No other IAM solution is currently supported.

Configuring SSO is optional. If you do not configure SSO, you must use Data Fabric user names and passwords for access to the cluster. While SSO is supported for Data Fabric core, it is not supported for the Installer or ecosystem components.

Keycloak Is Preinstalled and Preconfigured

Keycloak is the identity and access management (IAM) solution that provides single-sign-on (SSO) support for the Data Fabric. Starting with release 7.5.0, Keycloak is preinstalled and preconfigured when you install the `mapr-keycloak` package and specify the `-keycloak` option in [configure.sh](#) on page 3186 as part of cluster creation.

During cluster installation, Keycloak can be installed on all the nodes in the cluster. However, the Keycloak server is started on only one node. When installed, Keycloak is preconfigured with users, groups, and roles that enable integration of Keycloak with the Data Fabric. The following table describes the preconfigured items:

Keycloak Preconfigured Items	How Many?	Names	Notes
Users	1	admin	Any additional users that are added must be created with <code>uid</code> and <code>gid</code> attributes, as described in Adding New Users to Keycloak on page 1294.
Groups	1	fabric-manager	Any additional groups that are added must be created with the <code>gidNumber</code> attribute, as described in Adding a Group to Keycloak on page 1300.
Roles	3	fabric-manager infrastructure-admin developer	These are the only supported roles. The <code>developer</code> role is sometimes referred to as the "fabric user" role.
Clients	1	edf-client	This is the dedicated client for the Data Fabric. In Keycloak, a client is an application or service that can request authentication for a user.

Keycloak installation also gives you access to the Keycloak admin portal.

SSO and Temporary Tickets

Enhancements in release 7.3.0 and later allow clients that aren't aware of user passwords to access the cluster if they have a valid token from an SSO provider.

In Data Fabric installations that are not configured for SSO, users authenticate by providing a username and password and must obtain a user ticket to issue commands. The ticket enables RPC communication between various Data Fabric services. RPC communication cannot occur without a ticket.

Beginning with release 7.3.0, in installations where SSO is configured, a user provides a password to an SSO provider. The SSO provider authenticates the user and provides a JSON web token (JWT). The client presents the JWT to the CLDB using HTTPS. A CLDB plugin (new in release 7.3.0) functions as an HTTPS server and validates the JWT from the SSO provider. If the token is valid, the CLDB provides a short-lived ticket to the client.

Object Store and Temporary Tickets

Releases 7.3.0 and later also provide enhancements to enable MinIO Client (mc) communication with the HPE Data Fabric Object Store by using temporary tickets. In non-SSO installations, users and applications authenticate to the Object Store through S3 keys (AccessKey and SecretKey). Release 7.3.0 extended the MC framework to use `maprc li` with JWT to obtain a temporary AccessKey and SecretKey in the background. Optimizations in the CLDB allow the CLDB to cache the AccessKey and SecretKey for 15 minutes.

Accessing the Keycloak Administration Console

Describes how to start the Keycloak administration console so you can manage Keycloak and your SSO users.

If a new cluster has been created, you can access the Keycloak administration console by using these steps:

1. In a browser, specify the URL for the host that is running the WebServer. For example:

```
https://<FQDN_of_WebServer_node>
```

NOTE: If the cluster was upgraded from release 7.6.0 or a previous release, append the port (: 6443) to the URL. Newer deployments use port 443, which does not need to be appended because it is the default HTTPS port.

2. Click **Administration Console**:

The **Sign In** page is displayed:

3. Sign in using the default credentials:

Username: admin

Password: p@ssw0rd

IMPORTANT: HPE recommends that you change the password for the admin user soon after sign in. See [Changing the Keycloak admin Password](#) on page 1291.

Changing the Keycloak admin Password

Describes how to change the default Keycloak *admin* password to prevent unauthorized access to Keycloak and your Data Fabric user information.

The default admin password provided in the bundled version of Keycloak is a well-known password that must be changed immediately after installation. Use these steps to change the password:

1. Sign in to the Keycloak administration console as described in [Accessing the Keycloak Administration Console](#) on page 1290. The master realm information is displayed:

2. In the top right corner of the page, click the down arrow for the **admin** user, and select **Manage account**:

The account management information is displayed.

3. Click the **Personal Info**:

The **Personal Info** page is displayed.

4. In the left navigation pane, under **Account security**, click **Signing in**:

The **Signing in** page is displayed.

5. On the **Signing In** page, click **Update**:

Keycloak asks you to re-authenticate.

6. Type the default admin password again:

The **Update password** page is displayed.

7. Enter your new credentials, and click **Submit**:

8. Click **Back to security admin console** to return to the administration console:

9. In the top right corner of the page, click the down arrow for the **admin** user, and select **Sign out**:

10. Repeat step 1, signing in to the Keycloak administration console as described in [Accessing the Keycloak Administration Console](#) on page 1290. On the **Sign In** page, sign in as the **admin** user with your *new* password:

Adding New Users to Keycloak

Describes how to add new users in Keycloak so you can use them to sign in to the HPE Data Fabric.

By default, the Keycloak software provided with release 7.5.0 and later is preconfigured with only one user (the **admin** user). To add new users:

1. Sign in to the Keycloak administration console as described in [Accessing the Keycloak Administration Console](#) on page 1290. The master realm information is displayed.
2. In the left navigation pane, click **Users**:

The **Users** page is displayed, showing the preconfigured admin user.

3. Click **Add user**:

The **Create user** page is displayed.

4. In the **Username*** field, type the name of a new user, and click **Create**:

Users > Create user

Create user

Save [Revert](#)

7. Click **Save**.
8. Click the **Credentials** tab. The **Credentials** page shows **No credentials**.
9. Click **Set password**:

Users > User details

catherine Enabled Action

Details Attributes Credentials Role mapping Groups Consents Identity provider links Sessions

No credentials

This user does not have any credentials. You can set password for this user.

Set password

The **Set password for <new_user>** dialog box is displayed.

10. Enter a password for the new user, and confirm the password.
11. Move the **Temporary** slider to the **Off** position:

Set password for catherine

Password *

Password confirmation *

Temporary ⓘ ☒ Off

Save Cancel

12. Click **Save**. The **Set password?** confirmation dialog box is displayed.
13. On the **Set password?** confirmation screen, click **Save password**. The **Credentials** tab of the **User details** page is displayed.
14. Click the **Role mapping** tab. The **Role mapping details** are displayed.
15. Click the **default-roles-master** role.
16. Click the ellipsis () for the **default-roles-master** role, and select **Unassign**:

Users > User details

catherine Enabled Action

Details Attributes Credentials **Role mapping** Groups Consents Identity provider links Sessions

Search by name → ☒ Hide inherited roles **Assign role** Unassign 1-1

☒	Name	Inherited	Description	
☒	default-roles-master	False	\${role_default-roles}	⋮ Unassign

1-1

The **Remove mapping?** dialog box is displayed.

17. Click **Remove**. The **Role mapping details** page shows **No roles for this user**.
18. Click **Assign role**:

The **Assign roles to <new_user> account** is displayed.

19. In the **Name** column, click one of the preconfigured roles to assign it to the new user:

20. Click **Assign**. Next, you must assign the user to a group. Every user must belong to at least one group.
21. To add the user to a group, click the **Groups** tab. To add a new group, see [Adding a Group to Keycloak](#) on page 1300.
22. Click **Join Group**:

The **Join groups for user <new_user>** page is displayed:

23. To add the user to a group, click the check box for a group.
24. Click **Join**. The **Groups** page is displayed.
25. In the top right corner of the page, click the down arrow for the admin user, and select **Sign out**:

You can now sign in to the HPE Data Fabric using the new user.

Adding a Group to Keycloak

Describes how to add a Keycloak user group.

By default, the Keycloak software provided with release 7.5.0 and later is preconfigured with only one user group (the `fabric-manager` group). To add a new group:

1. Sign in to the Keycloak administration console as described in [Accessing the Keycloak Administration Console](#) on page 1290. The master realm information is displayed:
2. In the left navigation pane, click **Groups**.
3. Click **Create a group**.
4. Specify a name for the group, and click **Create**. The **Groups** page is displayed showing the new group. Click the link for the new group.
5. Click the **Attributes** tab.
6. In the **Key** field, type `gidNumber`, then specify a `gidNumber` value, such as 12345, in the **Value** field.
7. Click **Save**.
8. In the left navigation pane, click **Users**.
9. From the list of users, click a user that you want to add to the new group.
10. Click **Join Group**.
11. Click the name of the group to which you want to add the user, and click **Join**.

Integrating Your LDAP Directory with Keycloak

Keycloak can interface with an external LDAP directory so that LDAP users can access the HPE Data Fabric.

To add an external LDAP provider in Keycloak:

1. Sign in to the Keycloak administration console as described in [Accessing the Keycloak Administration Console](#) on page 1290.
2. In the left-navigation pane, click **User federation**. The **User federation** screen is displayed:

3. Click **Add Ldap providers**. The Keycloak **User federation** page is displayed.
4. Fill in the information for your LDAP provider. For field-specific information, click the online help icon (ⓘ) for the field. For Keycloak documentation, see [this page](#).

Using LDAP Mappers

Describes how to use mappers to auto-populate Keycloak with the mandatory attributes it needs for users and groups to access the Data Fabric UI.

If you integrated your LDAP Directory with Keycloak as described in [Integrating Your LDAP Directory with Keycloak](#) on page 1301, you must configure mappers to associate Keycloak user, role, and group attributes with your LDAP users. Three mappers need to be created:

- UID mapper
- GID mapper
- User group mapper

Creating the UID Mapper

To create the UID mapper:

1. Sign in to the Keycloak administration console as described in [Accessing the Keycloak Administration Console](#) on page 1290. The master realm information is displayed:
2. In the left-navigation pane, click **User federation**. The **User federation** screen appears.
3. Click the box for the LDAP provider that you configured in [Integrating Your LDAP Directory with Keycloak](#) on page 1301. The **LDAP** screen appears.
4. Click the **Mappers** tab to display the current list of mappers.
5. To add a mapper, click **Add mapper**. The **Create new mapper** screen appears.
6. Specify a name for the UID mapper. The following example uses the name uidjim:

7. In the **Mapper type** field, click the down arrow, and select `user-attribute-ldap-mapper`. The **Mapper details** screen appears.
8. Fill out the UID mapper as follows:

The screenshot shows the 'Create new mapper' form in the Keycloak administration console. The left sidebar contains navigation links: Manage, Clients, Client scopes, Realm roles, Users, Groups, Sessions, Events, Configure, Realm settings, Authentication, Identity providers, and User federation. The main content area is titled 'Create new mapper' and includes the following fields and settings:

- Name:** uidjlm
- Mapper type:** user-attribute-ldap-mapper
- User Model Attribute:** uidjlm
- LDAP Attribute:** uidNumber
- Read Only:** On
- Always Read Value From LDAP:** On
- Is Mandatory In LDAP:** Off
- Attribute default value:**
- Force a Default Value:** On
- Is Binary Attribute:** Off

At the bottom of the form are 'Save' and 'Cancel' buttons.

9. Click **Save**.

Creating the GID Mapper

To create the GID mapper:

1. Sign in to the Keycloak administration console as described in [Accessing the Keycloak Administration Console](#) on page 1290. The master realm information is displayed:
2. In the left-navigation pane, click **User federation**. The **User federation** screen appears.
3. Click the box for the LDAP provider that you configured in [Integrating Your LDAP Directory with Keycloak](#) on page 1301. The **LDAP** screen appears.
4. Click the **Mappers** tab to display the current list of mappers.
5. To add a mapper, click **Add mapper**. The **Create new mapper** screen appears.
6. Specify a name for the GID mapper.
7. In the **Mapper type** field, click the down arrow, and select user-attribute-ldap-mapper. The **Mapper details** screen appears.
8. Fill out the UID mapper as follows:

9. Click **Save**.

Creating the User Group Mapper

To create the User Group mapper:

1. Sign in to the Keycloak administration console as described in [Accessing the Keycloak Administration Console](#) on page 1290. The master realm information is displayed:
2. In the left-navigation pane, click **Clients**. The **Clients list** tab appears.
3. Click the **edf-client** entry.
4. In the right pane, click the **Client scopes** tab.
5. Click the **edf-client-dedicated** entry.
6. Click **Add mapper > By configuration**. The **Configure a new mapper** screen appears:

Configure a new mapper

Choose any of the mappings from this table

Name	Description
Allowed Web Origins	Adds all allowed web origins to the 'allowed-origins' claim in the token.
Audience	Add specified audience to the audience (aud) field of token.
Audience Resolve	Adds all client_ids of "allowed" clients to the audience field of the token. Allowed client means the client for which user has at least one client role.
Authentication Context Class Reference (ACR)	Maps the achieved LoA (Level of Authentication) to the 'acr' claim of the token.
Claims parameter Token	Claims specified by Claims parameter are put into tokens.
Claims parameter with value ID Token	Claims specified by Claims parameter with value are put into an ID token.
Group Membership	Map user group membership.
Hardcoded claim	Hardcode a claim into the token.
Hardcoded Role	Hardcode a role into the access token.
Pairwise subject identifier	Calculates a pairwise subject identifier using a salted sha-256 hash. See OpenID Connect specification for more info about pairwise subject identifiers.
Role Name Mapper	Map an assigned role to a new name or position in the token.
User Address	Maps user address attributes (street, locality, region, postal_code, and country) to the OpenID Connect 'address' claim.
User Attribute	Map a custom user attribute to a token claim.
User Client Role	Map a user client role to a token claim.
User Property	Map a built in user property (email, firstName, lastName) to a token claim.
User Realm Role	Map a user realm role to a token claim.
User Session Note	Map a custom user session note to a token claim.

- Click the **User Attribute** row. Selecting this row allows you to map a custom attribute to a token claim. The **Add mapper** screen appears.
- Fill out the form like this, using a name that is appropriate for your installation:

Confirming that Required Attributes Are Part of the JWT Token for a User

To confirm the required attributes:

1. Sign in to the Keycloak administration console as described in [Accessing the Keycloak Administration Console](#) on page 1290. The master realm information is displayed:
2. In the left-navigation pane, click **Clients**. The **Clients list** tab appears.
3. Click the **edf-client** entry.
4. In the right pane, click the **Client scopes** tab.
5. Click **Evaluate**.
6. In the **User** field, type the name of a user. For example, type the name of the fabric manager user:

7. Scroll down to check that the following four items are populated in the JWT token. If any of them are missing, there might be issues with user permissions:

Configuring Data Fabric Communications with Your SSO Server

Describes how to configure the HPE Data Fabric to work with an SSO server.

To enable your SSO provider to communicate with the Data Fabric release 7.4.0 or later must be installed, and you must configure SSO information by running the `maprcli cluster setsssoconf` command.

Note these considerations:

- Only the cluster admin or a user with the fabric manager role can run the `maprcli cluster setsssoconf` command.

- For a Data Fabric that was created using an installation method other than the seed node installation method, you must run the command only on the primary CLDB node. SSO information is propagated automatically to other CLDB nodes in the cluster.
- For a data fabric that was installed using the seed node method, you must run the command only on the primary CLDB node of the primary data fabric. SSO information is propagated automatically to other CLDB nodes and other fabrics in the global namespace.

To configure SSO:

1. Identify the primary CLDB node by using one of the following methods:

- On any node in the cluster, run the following `maprccli` command:

```
maprccli clustergroup getcgttable -showprimary true -json
```

- Log in to the Control System and go to the [service information page](#) for CLDB. The primary CLDB is the CLDB with a CLDB Mode equivalent to MASTER_READ_WRITE. For more information, see [Viewing CLDB Information](#).

2. Log on to the primary CLDB node as the cluster admin (typically the `mapr` user).

3. Run the [cluster setsssoconf](#) on page 2348 command, and specify the following options:

- `-issuerendpoint`
- `-providername`
- `-clientid`
- `-clientsecret`
- `-certfile`
- `-json` (optional)

For example:

```
maprccli cluster setsssoconf -issuerendpoint https://<IP_address>/realms/
TestReallm/
-providername keycloak -clientid testclient -clientsecret <secret>
-certfile /opt/mapr/keycloak/conf/<hostname>.cert -json
{
  "timestamp":1693834990616,
  "timeofday":"2023-09-04 06:43:10.616 GMT-0700 AM",
  "status":"OK",
  "total":1,
  "data":[
    {
      "status":"SUCCESS: SSO configuration set on CLDB."
    }
  ]
}
```

For information about each option, see [cluster setsssoconf](#) on page 2348.

Related reference

[cluster getsssoconf](#) on page 2339

Fetches the cluster-level SSO parameters.

[cluster setssocnf](#) on page 2348

Specifies how to configure the HPE Data Fabric to work with an SSO server.

Checking and Changing the Temporary Ticket Duration

Describes how to gather information about the temporary ticket and change the duration of the ticket.

In SSO-enabled installations, the default duration for the temporary ticket is 20 minutes. To check to see if a ticket has been generated, use the `ls` command to view the contents of the `/tmp` directory. For example:

```
ls -ltr /tmp/maprticket_*
-rw-rw-r--1 mapruser2 mapruser2 315 Feb 16 21:43 /tmp/maprticket_50088
```

To view the current ticket expiration, use the `maprlogin print` command:

```
$ maprlogin print
Opening keyfile /tmp/maprticket_200080
cluster-150-A: user = mapruser82, created = 'Mon May 15 20:23:42 PDT 2023',
expires = 'Mon May 15 20:43:42 PDT 2023', RenewalTill = 'Mon May 15
20:43:42 PDT 2023',
uid = 200080, gids = 20002, CanImpersonate = false, CanGenerateTicket =
false, isExternal = true, capabilities = [login, cv, a, fc]
```

To change the ticket duration:

1. Change to the root user (or use `sudo` for the following commands).
2. Modify the value of the `cldb.sso.temp.ticket.expiry.time` parameter in the `/opt/mapr/conf/cldb.conf` file. For more information, see [cldb.conf](#) on page 3358.
3. One node at a time on each CLDB node:
 - a. Stop Warden:

```
sudo service mapr-warden stop
```

- b. Restart Warden.

```
service mapr-warden start
```

Using CLI Commands Without a User Ticket When SSO Is Configured

Describes how to use temporary tickets with certain command line interfaces in SSO-enabled clusters.

In this case, "command line interface" refers to any of the following:

- `maprccli`
- `hadoop`
- `mc`
- `fuse (service start)`
- `loopback nfs (service start)`

When SSO is not configured, issuing a CLI command requires a user or client to have a valid ticket in order for the command line to connect to the CLDB service.

When SSO is configured, it is possible for the CLI to create temporary tickets automatically. To use this feature, you must set an environment variable before issuing the CLI command. For example:

```
export MAPR_JWT_TOKEN_LOCATION="/tmp/jwt"
```

Obtain the JWT from your SSO provider, and place it in a secure location that can be specified in the environment variable.

Exporting the environment variable creates a temporary ticket, enabling the CLI to talk to the CLDB server. This method permits the use of any command without a password for the duration of the ticket.

Using MinIO Client (mc) Without a User Ticket When SSO Is Configured

Describes how to use temporary tickets with MinIO Client (mc) commands in SSO-enabled clusters.

When SSO is not configured, issuing mc commands requires you to specify an AccessKey and SecretKey. You generate the keys by using the `maprc li s3keys generate` command, as described in [Getting Started with HPE Data Fabric Object Store](#) on page 620.

With SSO configured, it is still necessary to provide AccessKey and SecretKey. However, you can set an environment variable to satisfy this requirement. For example:

```
export MAPR_JWT_TOKEN_LOCATION="/tmp/jwt"
/opt/mapr/bin/mc alias setdemo https://<hostname> -f:9000
Added 'demo' successfully.
```

Obtain the JWT from your SSO provider, and place it in a secure location that can be specified in the environment variable.

After setting the JWT location, you can issue mc commands without specifying the AccessKey or SecretKey. When the environment variable is set, Data Fabric reads the JWT location from the environment variable and uses `maprc li` to contact the CLDB to obtain the AccessKey and SecretKey seamlessly.

To view the AccessKey and SecretKey for an alias, use the `mc alias ls` command. For example:

```
/opt/mapr/bin/mc alias ls demo
demo
  URL       : https://127.0.0.1:9000
  AccessKey : 6TTSP773RPYKQ8511SWVQT924MTA4M57U2BYKVB5Q83GN0ABR
  SecretKey : 8KFL9W77LFMG36MJXGD057QZPL9FMN73BFJ5CDSEW09LNMHSW
  API       : s3v4
  Path      : auto
```

SSO User Login from a Cluster Node or Edge Node

Describes how to log in from a cluster node or edge node using an SSO user.

SSO users who want to log in to a cluster node or edge node must obtain the JWT from the SSO provider, and place it in a secure location that can be specified in an environment variable.

Export the JWT token file path as follows. For example:

```
export MAPR_JWT_TOKEN_LOCATION="/tmp/testuser1.jwt"
```

Exporting the environment variable creates a temporary ticket, enabling `maprc li` to talk to the CLDB server. This method permits the use of any `maprc li` command without a password for the duration of the ticket.

Temporary Ticket Expiration

Describes what happens when a temporary ticket expires.

Ticket Expiration and JWT Expiration

As described in [Checking and Changing the Temporary Ticket Duration](#) on page 1309, the default duration for the temporary ticket is 20 minutes. You can increase the duration. However, it is important to understand that the JWT has an expiry time too. The SSO provider controls the JWT expiration. Data Fabric software recognizes both expiry settings and expires the temporary ticket when the lesser expiry setting is reached.

For example, if the temporary ticket expiration is set to 2880 minutes (2 days), and the JWT expiration is set to one day, the temporary ticket will expire in one day.

When a Ticket Expires

If a temporary ticket expires while you are using `maprc li`, `hadoop`, or the Minio Client (`mc`), and you have exported the location of the JWT, `maprc li` or `mc` will create a new ticket automatically. If you have not exported the location of the JWT, as described in [Using CLI Commands Without a User Ticket When SSO Is Configured](#) on page 1309 and [Using MinIO Client \(mc\) Without a User Ticket When SSO Is Configured](#) on page 1310, the command prompt will indicate that the ticket is not valid.

Roles and Permissions When SSO Is Configured

Describes the roles supported by the HPE Data Fabric in SSO-enabled clusters.

SSO-configured clusters support the following roles:

Role	Permissions	ACL Permission Code
Developer (fabric user)	Readonly and create volume permission	login, cv, cp
Infrastructure Admin	Permission to log in and start or stop services	login, ss
Fabric Manager	Full control of the cluster	login, cv, cp, fc

When SSO is not configured, Data Fabric clusters implement permissions through cluster-level access control lists (ACLs). See [Creating Cluster-Level ACLs](#) on page 2123.

When SSO is configured, Data Fabric relies on the roles defined in the JSON web token (JWT). For example:

```
"userRoles": [
  "default-roles-user46",
  "offline_access",
  "admin",
  "developer",
  "uma_authorization",
  "cluster-admin"
],
```

The LDAP administrator configures these roles when a user is added to LDAP. The roles are then passed into the JWT. You can view the role permissions by issuing the `mapr login print` command:

```
maprlogin print
testcluster: user = mapr, created = 'Fri Mar 10 02:10:34 PST 2023', expires
= 'Fri Mar 10 02:30:34 PST 2023', RenewalTill = 'Fri Mar 10 02:30:34 PST
2023',
uid = 5000, gids = 5000, 5001, CanImpersonate = true, CanGenerateTicket
= false, isExternal = true, isRemoteTempTicket = false, capabilities =
[login, cv, a, fc]
```

Data Fabric honors permissions embedded in the JWT first and then honors permissions in cluster-level ACLs.

About Access and Refresh Tokens

Describes how to use the downloadable tokens provided for client access in the Data Fabric UI.

How Clients Use Tokens

In Data Fabric deployments where SSO is configured, you must provide an SSO user name and password for access to a fabric. Clients that aren't aware of SSO user names and passwords can gain access to RPC communications by using JSON web tokens (JWTs). A JSON Web Token (JWT) is a method for securely transmitting information between services in a computing system.

In a Data Fabric deployment, the Keycloak SSO provider can generate tokens when a user supplies an SSO user name and password. The tokens enable the creation of short-lived Data Fabric tickets that facilitate communication with the file system.

Issuing commands from any of the following command line interfaces (CLIs) or clients requires the user or client to have a valid ticket.

- `maprc li`
- `hadoop`
- `mc`
- `fuse (service start)`
- `loopback nfs (service start)`

The ticket allows the command line to connect to the CLDB service. To facilitate the process, you must obtain a token from the SSO provider and place it in a secure location that can be specified in an environment variable. Exporting the environment variable creates a temporary ticket, enabling the CLI to talk to the CLDB server. This method permits the use of any command without a password for the duration of the ticket.

For more information about Data Fabric tickets, see [Managing Tickets](#).

Downloading the Tokens

In the Data Fabric UI, you use the **Client library** command to download the tokens. The tokens are contained in the `jwt_tokens.tar.gz` file, which are extracted to the client. The `jwt_tokens.tar.gz` file contains the following token files:

Token Type	File	Function
Access	jwt_access	Encapsulates the user's authentication information within the fabric.
Refresh	jwt_refresh	Enables the creation of a new access token when the current access token expires.

For more information about downloading the tokens, see [Installing Client Libraries](#).

Exporting the Tokens

To enable a client to use the tokens, you must export the path to each token. This must be done each time you establish a host session. To export the paths:

Client	To export the tokens . . .
Hadoop	<p>Use these commands:</p> <pre>export MAPR_JWT_TOKEN_LOCATION="/root/jwt_access" export MAPR_JWT_REFRESH_TOKEN_LOCATION="/root/jwt_refresh"</pre> <p> NOTE: Some use cases, such as submitting YARN applications, require that the JWT user must exist in the federated identity store (for example, LDAP), and is resolvable on the cluster nodes via PAM.</p>
Fuse POSIX	<p>Add the export paths shown for the Hadoop client in the first row of this table to the top of the following file:</p> <pre>/opt/mapr/initscripts/mapr-posix-client-basic</pre>
Loopback NFS	<p>Add the export paths shown for the Hadoop client in the first row of this table to the top of the following file:</p> <pre>/usr/local/mapr-loopbacknfs/initscripts/mapr-loopbacknfs</pre>

Alternatively, you can add the tokens to the `core-site.xml` file. Adding them to `core-site.xml` file causes the fabric to use the designated tokens *every time you log on*. To add the tokens, specify the following property in the `core-site.xml`:

```
<property>
  <name>fs.mapr.sso.tokenpath</name>
  <value>/root/jwt_access</value>
</property>
```

Token and Ticket Expiration and Renewal

Tokens and tickets expire after a short time. By default, Keycloak-generated tokens expire after two (2) hours. Short-lived tickets expire after 20 minutes.

If an access token expires or becomes invalid, the client application can use a refresh token to obtain a new access token without requiring the user to re-authenticate. The client application sends Keycloak a token-refresh request along with the current refresh token. Keycloak validates the refresh token and issues a new access token. This automatic-refresh mechanism repeats itself to allow client jobs to run for days or weeks as long as the tokens remain valid.

Changing Token and Ticket Durations

You can change the valid duration of tokens and tickets. Note that a ticket is valid for no more than 20 minutes or the expiry time of its associated access token, *whichever is lower*. Thus, if a ticket expiry time is

set for 20 minutes and the associated access token is valid only for 10 minutes, the ticket will be valid for only 10 minutes.

CAUTION: Setting long lifetimes for tokens or tickets can introduce a considerable security risk. Hewlett Packard Enterprise recommends finding a balance between security and usability and, whenever possible, erring on the side of security in your use of tokens and tickets.

To check or change the expiry setting for short-lived tickets, see [Checking and Changing the Temporary Ticket Duration](#).

To change the expiration setting for a token, you must be the fabric manager and have access to the Keycloak UI.

Access Token Expiry

You can configure the access token expiry time at the realm level or at the client level.

1. Log in to the Keycloak admin console. See [Accessing the Keycloak Administration Console](#) on page 1290.
2. Select the realm for which you want to configure the access token expiry time.
3. Go to the **Realm Settings > Tokens** tab.
4. In the **Access Token Lifespan** field, specify the desired expiration time for the access tokens in hours, minutes, or days.
5. Save your changes.

Refresh Token Expiry

You typically configure the refresh token expiry time at the realm level:

1. Log in to the Keycloak admin console. See [Accessing the Keycloak Administration Console](#) on page 1290.
2. Select the realm for which you want to configure the access token expiry time.
3. Go to the **Realm Settings > Sessions** tab.
4. In the **SSO Session Max** field, specify the desired maximum lifespan for refresh tokens in minutes, hours, or days.
5. Save your changes.

Invoking Data Fabric REST API when SSO is configured

Describes how an SSO user can invoke Data Fabric REST API.

SSO users can access Data Fabric REST API by using a bearer token.

As an SSO user, you must first obtain a bearer token from Keycloak.

Use the following curl command to obtain a bearer token from Keycloak:

```
curl -X POST \ https://<data_fabric_server_ip>/realms/master/
protocol/openid-connect/token \ -H 'Content-Type: application/
x-www-form-urlencoded' --data-urlencode 'client_id=edf-client'
\ --data-urlencode 'grant_type=password' --data-urlencode
'client_secret=<client_secret>' \ --data-urlencode
'scope=openid' --data-urlencode 'username=<username>' --data-urlencode
'password=<password>'
```

Once you obtain a bearer token, you can invoke the Data Fabric REST API with authentication by using the obtained bearer token:

```
curl "https://<data_fabric_server_ip>:8443/rest/<command>/<subcommand>"
\ --header 'Authorization: Bearer <bearer token obtained from Keycloak>'
```

NOTE: The aforementioned steps are applicable to all maprccli commands invoked using REST. For a complete maprccli reference, see [maprccli and REST API Syntax](#) on page 2266.

Managing Permissions

Provides an overview of managing user permissions at the cluster, volume and file system levels.

You can manage user permissions at the cluster, volume, and filesystem levels. Cluster and volume permissions use access control lists (ACLs) to specify which actions a user can perform on a cluster or volume. File system permissions and [ACEs](#) control user access to volumes, directories, and files, similar to Linux file permissions. Users get the permissions that are directly assigned to them as well as the permissions assigned to the groups they are in. You must have `fc` permissions to manage permissions.

Adding Cluster Permissions

Describes how to set cluster permissions for users and groups through the Control System and the CLI.

About this task

The following table lists the actions that a user can perform on a cluster with the corresponding UI columns and codes used in the cluster [Access Control List \(ACL\)](#):

UI	ACL	Allowed Action
Login	login	Log in to the Control System, use the API and command-line interface, read access on cluster and volumes
Start/Stop Service	ss	Start and stop services
Create Volumes	cv	Create volumes
Create Security Policy	cp	Required to create security policies. Users with Administrator (a) access can assign this permission to other administrators.
Administrator	a	Administrative access (can edit and view ACLs , but cannot perform cluster operations)
Full Control	fc	Full control over the cluster. This enables all cluster-related administrative options with the exception of changing the cluster ACLs .

Setting Permissions Using the Control System

About this task

Complete the following steps to add cluster permissions in the Control System:

Procedure

1. Log in to the Control System and click **Admin > User Settings > Permissions**.

2. Under **USER PERMISSIONS**, select the type and specify the name of the user or group in the **Name** field.
3. Select the checkbox associated with the permissions you want to grant to the user or group.
4. Click **Add Another** to add permissions for another user or group.
Each row lets you assign permissions to a single user or group.

NOTE: A user gets the permissions directly granted to the user as well as permissions granted to any group to which the user belongs.

5. Click **Save Changes** to save the changes.

Setting Permissions Using the CLI or the REST API

About this task

To set permissions using the CLI, run the following command:

```
/opt/mapr/bin/maprcli acl set
[ -cluster <cluster name> ]
[ -group <group> ]
[ -name <name> ]
-type cluster|volume|securitypolicy
[ -user <user> ]
```

See [acl set](#) on page 2276 for complete reference information.

Granting a User Full Control from the Command-Line

About this task

The user who has full control over the cluster can manage all aspects of the cluster operation except assign permissions for other users.

Complete the following steps to give full administrative control to a user:

Procedure

1. Log on to any cluster node as root (or use sudo).
2. Execute the following command, replacing <user> with the username of the account that gets administrative control: `sudo /opt/mapr/bin/maprcli acl edit -type cluster -user <user>:fc`

For general information about users and groups in the cluster, see [Managing Users and Groups](#).

Removing Cluster Permissions

Describes how to remove cluster permissions using the Control System or the CLI.

Removing Cluster Permissions Using the Control System

About this task

Complete the following steps to remove cluster permissions in the Control System:

Procedure

1. Log in to the Control System and click **Admin > User Settings > Permissions**.
2. Remove the desired permissions:

- To remove all permissions for a user or group, click  associated with the row.
- To change the permissions for a user or group, deselect the checkbox associated with the permissions you wish to revoke from the user or group.

3. Click **Save Changes** to save the changes.

Removing Cluster Permissions Using the CLI or REST API

About this task

The `acl set` command specifies the entire [ACL](#) for a cluster or volume. Any previous permissions are overwritten by the new values, and any permissions omitted are removed. To remove cluster permissions, run the `acl set` command and omit the permissions to remove. See [acl set](#) on page 2276 for complete reference information.

Blocking Users Using the CLI

Explains how to block users using the CLI.

About this task

You can block users using the CLI. When a user is blocked, all existing tickets for the user are canceled and any request sent by the user that has a ticket older than the blocked timestamp is rejected. For more information, see [How Tickets Work](#) on page 2102.

Blocking Users Using the CLI or REST API

About this task

The basic command to blacklist a user is:

```
maprcli denylistuser -user <user name>
```

For complete reference information, see [blockaccess user](#) on page 2314.

Managing the Cluster

Lists the settings for managing the Data Fabric cluster.

You can add licenses, set up auditing of cluster administration, configure disk space balancer tool settings and Role Balancer settings, configure how MapReduce programs run, allocate quotas for users and groups and set the cluster reserve limit, and generate the DNS Gateway record for table replication using both the Control System (click **Admin > Cluster Settings**) and the CLI.

Managing Auditing

Provides instructions for using Data Fabric auditing features.

You can enable auditing of cluster administration and data-access operations by using the Control System and the CLI. Enabling auditing of the file system, table, and streams operations requires running a command on a cluster, a command on individual volumes in the cluster, and a command on individual directories, files, and Data Fabric tables and streams within those volumes.

These steps are summarized in the following table:

Steps to enable auditing				
	Enable auditing of cluster administration	Enable data auditing on the cluster	Enable auditing of individual volumes	Enable auditing of individual directories, files, and HPE Data Fabric Database tables

Auditing of cluster administration		Not applicable	Not applicable	Not applicable
Auditing of directories, files, and HPE Data Fabric Database tables	Not applicable			

Prerequisites for enabling auditing

- If you upgraded your Data Fabric cluster from version 4.1 or earlier, you must enable the auditing feature.
 - Run `maprcli config save -values {"mfs.feature.audit.support":"1"}`
 - To verify that the feature is enabled, run `maprcli config load -json | grep "mfs.feature.audit.support"`
- Only the root user or mapr user can enable or disable auditing.

Enabling and Disabling Auditing of Cluster Administration

Describes how to enable and disable cluster administration auditing using the Control System and the CLI.

About this task

You can enable or disable auditing of cluster-management operations on a HPE Data Fabric cluster using the Control System and the CLI. See [Auditing Cluster Operations](#) on page 918 for the complete list of cluster management commands that are audited.

*Enabling and Disabling Auditing of Cluster Administration Using the Control System***About this task****Procedure**

1. Log in to the Control System and go to the **Auditing** tab in the **Admin > Cluster Settings** page.
2. Move the **Enabled** slider to **Yes** to enable and **No** to disable cluster auditing.
3. Click **Save Changes** for the changes to take effect.

*Enabling and Disabling Auditing of Cluster Administration Using the CLI or REST API***About this task**

To enable or disable auditing of cluster-management operations on a Data Fabric cluster, run the `maprccli audit cluster` command.

```
maprccli audit cluster -enabled <true | false>
```

For complete reference information, see [audit cluster](#) on page 2310.

Enabling and Disabling Auditing of Data Access Operations

Describes how to enable or disable auditing of data-access operations using the Control System and the CLI.

About this task

See [Auditing Data Access Operations](#) on page 920 for the complete list of data-access operations that can be audited.

*Enabling and Disabling Auditing of Data Access Operations Using the Control System***About this task**

To enable or disable auditing of data-access operations on a cluster:

Procedure

1. Log in to the Control System and go to the **Auditing** tab in the **Admin > Cluster Settings** page.
2. Set the following:

Enabled	Move the slider to Yes to enable or No to disable data auditing.
Maximum Size	Set the size in GB, which when reached causes an alarm to be sent to the dashboard on the Control System. The alarm is to notify the cluster administrator that the audit log size is large enough to need administrator intervention. The audit log continues to grow until the administrator takes action or until the retention period ends.
Retain Logs for	Set the period of time in days to keep the data in the audit log. After this period elapses, the content of the file is deleted and new entries are added to the file until the retention period elapses.

3. Click **Save Changes** for the changes to take effect.

NOTE: This action does not cause auditing to start for operations within the volumes. It only sets a flag that indicates that you allow auditing of individual volumes to be enabled when volume is created or modified.

*Enabling and Disabling Auditing of Data Access Operations Using the CLI or REST API***Procedure**

1. To enable or disable auditing of the filesystem, table, and streams operations on a cluster, run the `maprcli audit data` command.

This command does not cause auditing to start for operations within those volumes. It only sets a flag that indicates you allow auditing of individual volumes to be enabled with the `maprcli volume audit` command. The audit logs for file operations, table operations, and stream operations are affected by the value that you set for the `-retention` parameter.

2. To enable or disable auditing for a particular volume, run the `maprcli volume audit` command. To verify that auditing is enabled for a volume, run the `maprcli volume info` command. You can grep with the search term `'audited\|coalesce'`.

```
maprcli volume info -name <volume_name> -json | grep -i 'audited\|coalesce'
```

The output of the command should be as follows, with a 1 for the audited key and the value for the coalesceinterval key: `"audited":1, "coalesceInterval":2`

3. To enable or disable auditing for a particular directory, file, HPE Data Fabric Database table, or streams that existed in a volume at the time that you ran the `maprcli volume audit` command, run the `hadoop mfs` command with the `-setaudit` parameter.

```
hadoop mfs -setaudit <on|off> <directory|file|table>
```

NOTE: Wildcards are not supported for the names of filesystem objects in this command.

Enabling auditing on a directory does not enable auditing on the files that already exist in the directory, though new files and directories created in the directory will have auditing enabled. For example, if you run this command on the root directory of a volume, all new files, directories, and tables that are subsequently created in the volume are audited. The creation of those objects is also audited.

Results

After enabling auditing, if you create a:

- Snapshot of a volume, the snapshot inherits the audit settings of the original volume.
- Local mirror or remote mirror of a volume, you must run the `maprcli volume audit` command to enable auditing on the mirror volume. Auditing for particular directories, files, and HPE Data Fabric Database tables in a mirror volume is automatically enabled if auditing is enabled for them in the source volume.

How Does Auditing Work?

Explains how auditing works on Data Fabric objects.

When you enable the auditing of a particular directory, file, table, or stream, you set the *audit bit* to "on" for that object. You can tell whether auditing is enabled for a directory, file, or table by checking the status of the object's audit bit.

For example, the volume as shown in the following tree diagram, consists of the root directory, the two directories `dir1` and `dir2`, and two files in directory `dir1`. Every directory, file, table, and stream in a volume has an "audit bit" associated with it. You can tell whether, say, `dir1` has its audit bit on and is

therefore enabled for auditing by running the `hadoop mfs -ls` command. The output of the command might look like as follows:

```
drwxrwxrwx Z U U 3 root root 100 2015-05-20 21:09 192473738 /dir1
```

The second U indicates that auditing is not enabled on the directory.

However, an A in place of that U indicates that auditing is enabled on the directory:

```
drwxrwxrwx Z U A 3 root root 100 2015-05-20 23:41 192473738 /dir1
```

In the first diagram, as well as in the next two diagrams, U indicates that the audit bit is turned off for a filesystem object and A indicates that the audit bit is on for that object. After you run `maprc li volume audit` on the volume, none of the audit bits are on:

```
/          U
-/dir1     U
-file1     U
-file2     U
-/dir2     U
```

Suppose you enable auditing on the root directory by running this command:

```
hadoop mfs -setaudit on /
```

Then, you create the file `file3` in `dir2` and you create the directory `dir3` and the file `file4` in it. The tree diagram now looks as follows :

```
/          A
-/dir1     U
-file1     U
-file2     U
-/dir2     U
-file3     U
-/dir3     A
-file4     A
```

The audit bit is still U on `dir1`, and the files are in `dir1`, and `dir2`. The new file `file3` in `dir2` inherits the audit bit from `dir2`.

`dir3` inherits the audit bit from the root folder, so the audit bit for `dir3` is A. Moreover, `file4` inherits the audit bit from `dir3`, so its audit bit is A, as well.

Next, you run the following command to enable auditing in `dir1`:

```
hadoop mfs -setaudit on /dir1
```

Then, you create the file `file5`. The new file inherits the audit bit from its parent folder, so it is enabled for auditing immediately after it is created. However, `file1` and `file2` still have the audit bit turned off.

```
/          A
-/dir1     A
-file1     U
-file2     U
-file5     A
-/dir2     U
-file3     U
-/dir3     A
-file4     A
```

As file1 and file2 existed before you turned on the audit bit for their parent folder, you need to enable auditing for them as follows:

```
hadoop mfs -setaudit on /dir1/file1
```

```
hadoop mfs -setaudit on /dir1/file2
```

Selective Auditing of File-System, Table, and Stream Operations Using the CLI

Explains how to audit Data Fabric objects selectively.

Administrators can specify file-system, table, or stream operations to include or exclude from auditing. The operations that can be included or excluded from auditing are listed [here](#).

Including or excluding specific operations from auditing requires running the `maprcli` command. You can specify the list of operations to include or exclude from auditing during volume creation using the `maprcli volume create` command, and afterwards using the `maprcli volume modify` or `maprcli volume audit` command.

To:

- Include operations for auditing, use the plus sign (+) before the operation.
- Exclude operations from auditing, use the minus sign (-) before the operation.

NOTE: If the first operation in the list is to be excluded from auditing, it must be preceded by two minus (- -) signs. Subsequent operations to exclude from auditing must be preceded by only a single minus (-) sign, whether or not the first operation was included (using a plus (+) sign) or excluded (using two minus (- -) signs).

NOTE: If neither (plus (+) or minus (-)) sign is specified before an operation, the given operation is included for auditing.

Including and/or Excluding Operations

Including or excluding specific operations from auditing requires running the `maprcli` command.

Include or Exclude Operations During Volume Creation

During volume creation, the specified list of operations must either be included for auditing or excluded from auditing. You cannot specify a mixed list of included and excluded operations.

By default, all other operations other than the specified operations are:

- Included for auditing if the specified list is a list of excluded operations.
- Excluded from auditing if the specified list is a list of included operations.

Examples

The following example shows how to enable auditing and exclude specific operations (such as lookup, read, and write) from auditing:

```
maprcli volume create -name test-volume -path /test/
test-volume -auditenabled true -dataauditops --lookup,-read,-write
```

In the above example, operations other than the ones specified are included for auditing.

The following example shows how to include all operations except lookup for auditing:

```
maprcli volume create -name test-volume -path /test/
test-volume -dataauditops --lookup
```

The following example shows how to include only chown operation for auditing and exclude all other operations from auditing:

```
maprcli volume create -name test-volume -path /test/
test-volume -dataauditops +chown
```

Include and Exclude Operations After Volume Creation

After volume creation, you can include and exclude certain operations from auditing using the [volume modify](#) or [volume audit](#) command. When you modify a volume (by running the `volume modify` command) or when you enable volume auditing (by running the `volume audit` command), you can specify a mixed list of included and excluded operations. There are no changes to operations that are not specified with the command.

For the list of operations that can be included and/or excluded from auditing, see [Auditing of Filesystem Operations and Table Operations](#).

Examples

The following example shows how to include create operation for auditing and exclude lookup operation from auditing:

```
maprcli volume modify -name test-volume -dataauditops +create, -lookup
```

The following example shows how to include all operations except lookup for auditing:

```
maprcli volume audit -name test-volume -dataauditops +all, -lookup
```

Grouping of Operations

You can group all file system and table operations using the keyword `all`. If the operations to:

- Include for auditing are specified using the keyword `all`, you cannot specify other individual operations to include as well.

For example, the following is *not* allowed:

```
maprcli volume modify -name v1 -dataauditops +all,+mkdir
```

- Exclude from auditing are specified using the keyword `all`, you cannot specify other individual operations to exclude as well.

For example, the following is *not* allowed:

```
maprcli volume modify -name v1 -dataauditops --all,-mkdir
```

If operations are specified using the keyword `all`, ensure that the individual operations specified with the same command are used to:

- Include, if `all` is used to exclude from auditing.
- Exclude, if `all` is used to include for auditing.

For example, the following is a valid combination of operations to audit:

```
maprcli volume modify -name v1 -dataauditops +all,-mkdir,-lookup
```

Verifying Selective Auditing of Operations

After you set up the list of operations to include and/or exclude from auditing, you can retrieve and verify the list of included and/or excluded operations using the `maprcli volume info` command. When you run the `volume info` command, the output will show the list of operations:

- Excluded (disableddataauditoperations) from auditing.
- Included (enableddataauditoperations) for auditing.

Example

The following example shows how to retrieve and verify the list of operations that are:

- Excluded from auditing
- Included for auditing

```
maprcli volume info -name test-volume -path /test/test-volume -json
```

Output

```
{
  "timestamp":1435182867317,
  "timeofday":"2016-01-10 02:54:27.317 GMT-0700",

Specifying Operations to Audit Using a Security Policy

About this task

You can specify the directory, file, and table operations to audit in a security policy. If you specify the operations to audit in a security policy and tag data objects (such as volumes and tables) with the policy, the enforcement mode setting in the policy is used to determine how the setting affects auditing of operations on the data objects. For more information, see [Volume-Level Security Policy Enforcement Mode](#) on page 932.

You can specify the directory, file, and table operations to audit in a security policy using the Control System, CLI, and the REST API.

Specifying Audit Operations in a Security Policy Using the Control System

Procedure

1. Log in to the Control System and go to one of the following pages:
 - [Create Security Policy](#) to set the list of operations to audit when creating a policy.
 - [Edit Security Policy](#) to set new or modify existing list of operations to audit.
2. Move the slider associated with **Enable Audit Operations** from **No** to **Yes** to enable auditing if it is already not enabled.
3. Choose the **Default** radio button to accept the default list of operations to audit or choose the **Custom** radio button to select/deselect the operations to audit.
For more information on the list of operations that can be audited, see [Auditing Data Access Operations](#) on page 920.
4. Specify or modify other properties as needed and click **Save** for the changes to take effect.
For more information, see:
 - [Creating a Security Policy](#) on page 2165
 - [Modifying a Security Policy](#) on page 2174

Specifying Audit Operations in a Security Policy Using the CLI and REST API

Enabling and Disabling Audit Streaming Using the CLI

Explains how to enable or disable audit streaming using the CLI.

About this task

[Audit streaming](#) is not enabled by default. You can enable or disable audit streaming using the CLI.

Procedure

Run the following command to:

- Enable audit streaming:

```
maprcli config save -values '{"mfs.enable.audit.as.stream":"1"}'
```

NOTE: If you are re-enabling audit streaming after disabling it, the audit stream starts publishing to topics from where it left off processing audit logs.

- Disable audit streaming:

```
maprcli config save -values '{"mfs.enable.audit.as.stream":"0"}'
```

Configuring Balancer Settings

Provides an overview of the HPE Data Fabric disk space and replication role balancers.

You can use the disk space balancer and the replication role balancer to redistribute data and containers in the HPE Data Fabric storage layer to ensure maximum performance and efficient use of space. The disk space balancer works to ensure that the percentage of space utilized on all storage pools in the cluster is similar and prevent nodes from being overloaded. The replication role balancer changes the replication roles of containers so that the replication process uses network bandwidth evenly.

You can pipe the `maprcli config load` command through `grep` to view the balancer configuration values.

Example:

```
maprcli config load -json | grep balancer
  "cldb.balancer.disk.deltaToRepopulateStoragePoolsBins":"5",
  "cldb.balancer.disk.deltatorepopulatestoragepoolsbins":"5",
  "cldb.balancer.disk.max.switches.in.nodes.percentage":"10",
  "cldb.balancer.disk.overused.threshold":"90",
  "cldb.balancer.disk.sleep.interval.sec":"120",
  "cldb.balancer.disk.threshold.percentage":"70",
  "cldb.balancer.logging":"0",
  "cldb.balancer.role.max.switches.in.nodes.percentage":"10",
  "cldb.balancer.role.paused":"1",
  "cldb.balancer.role.skip.container.active.sec":"600",
  "cldb.balancer.role.sleep.interval.sec":"900",
  "cldb.balancer.startup.interval.sec":"1800",
  "cldb.disk.balancer.enable":"0",
  "cldb.role.balancer.replicascount.tolerance":"1",
  "cldb.role.balancer.replicassize.tolerance":"5",
  "cldb.role.balancer.strategy":"BySize",
  "prevent.volume.skew.by.diskbalancer":"0",
```

You can use the `config save` command to set the appropriate balancer configuration values.

Example:

```
maprcli config save -values
{"cldb.balancer.disk.max.switches.in.nodes.percentage":"20"}
```

NOTE: By default, the balancers are turned off.

- To turn on the disk space balancer, use `config save` to set `cldb.disk.balancer.enable` to 1.
- To turn on the replication role balancer, use `config save` to set `cldb.balancer.role.paused` to 0.

Disk Space Balancer

Describes the role of the disk space balancer.

The *disk space balancer* is a tool that balances disk space usage on a cluster by moving containers between nodes (subject to the constraints of the topology of the volume to which a container belongs). This movement of containers ensures that the percentage of space used on all the disks in the cluster is similar. The disk space balancer balances at the level of storage pools (SPs), keeping them at the same utilization level as the cluster average.

**NOTE:**

- Utilization Level of a SP = (Used space of the SP / Storage capacity of the SP)
- Cluster Average = (Used space across all SPs / Capacity of all SPs)

The disk space balancer distributes containers from highly utilized storage pools on one node in a cluster to less utilized storage pools on other nodes in the same cluster. It accomplishes this by first classifying storage pools into different bins (based on their utilization level). It checks every storage pool on a regular basis (every 2 minutes by default) and then classifies storage pools into bins based on their percentage utilization.

After classifying the storage pools into bins, the disk space balancer then moves containers (in two phases) out of the storage pools with more containers to storage pools with fewer containers. That is, it moves containers out of storage pools in higher bins to storage pools in lower bins in two phases:

- Phase 1 — storage pools in 'Overused' and 'Above Average' bins are balanced.
- Phase 2 — storage pools in 'Average' and 'Below Average' bins are balanced.

NOTE: Movement of containers in phase 2 happens only when there are not many containers scheduled to be moved in phase 1, because movement of container at any point in time is throttled.

In both phases, the disk balancer attempts to move containers from storage pools in the highest utilized bin (the source SP) to suitable storage pools in the lowest utilized bin (the destination SP). If a suitable SP could not be found as the destination, the balancer attempts to move a container to the next least utilized bin. An SP is not deemed suitable as the destination if:

- Moving a container to that SP would cause the SP to move to the next bin.
- Data movement into the file server to which the SP belongs is blocked.
- SP is not in the same topology as specified by the volume.
- Certain number of containers are currently being moved into the SP.

NOTE: The number of simultaneous moves to a SP is capped at 2.

- SP is in the same bin as the source SP.
- Many containers of a container group associated with the same tiering-enabled volume reside on the SP.

This feature ensures that containers of a container group associated with a tiering-enabled volume are distributed evenly across SPs and do not gather in a few SPs. The balancer accomplishes this by determining whether the destination SP has containers from the container group for the volume associated with the container that is identified for being moved to the destination SP.

An SP or its containers are not considered for balancing if:

- Data movement from the file server to which the SP belongs is blocked.
- Container was active (that is, written to) in the previous 5 minutes.
- Containers were deleted in the previous minute.

This is to allow space reclamation. If necessary, the bin will be balanced during the next iteration of the disk balancer.

- Percentage of data that is being transferred out of an SP is greater than or equal to 2% of the SP's storage capacity.
- Certain number of containers are currently being moved out of the SP.

NOTE: The number of simultaneous moves out of an SP is capped at 2.

Sample Disk Balancer Settings for Organization of Bins

The following example illustrates disk balancer settings and the corresponding organization of bins to represent storage pool utilization:

In the preceding example, the:

- Average cluster space utilization is 65%.
- Average bin size is 10%. Hence, the average bin spans 5% on each side of the average space utilization.
- Overused threshold is 90%.
- Below average bin size is 20%.

Below average bin utilization is partitioned into required number of bins (3). During division, the bin that is immediately to the left of the average bin might not span the default value. In other words, if the average bin spans from 50% to 60%, the below average bins will be cast as 0-20%, 20-40%, 40-50%.

- Above average bin size is 10%.

Since the overused threshold is 90%, the above average bins span the utilization from the right boundary of the average bin up to the overused threshold. As with below average bins, as many possible bins are cast with the size of the above average bin, leaving the remaining utilization to be covered by the last (right-most) above average bin.

Enabling and Configuring Disk Balancer

Describes how to enable or disable the disk space balancer and other settings using the Control Panel and the CLI.

About this task

Enabling and Configuring Disk Balancer Using the Control System

About this task

To enable and configure disk space balancer using the Control System:

Procedure

- Log in to the Control System and click **Admin > Clusters Settings > Balancer**.
- In the Disk Balancer section, move the **Enabled** slider to **Yes**.
To enable disk space balancer from the command-line, see [Configuring Disk Balancer Execution](#) on page 1330.

3. Select one of the presets or specify a custom percentage for **Threshold** and **Concurrent Disk Rebalancer** settings. You can :

- **Disk Balancer Preset:**

Moderate (Default)

- **Threshold** — 70%
- **Concurrent Disk Rebalancer** — 10%

Rapid

- **Threshold** — 50%
- **Concurrent Disk Rebalancer** — 5%

Relaxed

- **Threshold** — 90%
- **Concurrent Disk Rebalancer** — 25%

- **Custom**, use the slider to set the threshold and concurrent disk rebalancer percentages.

Here:

Threshold	Specifies the minimum utilization threshold for a storage pool to become eligible for rebalancing. Default value is 70%.
Concurrent Disk Rebalancer	Specifies the maximum percentage of data that can be rebalanced. The cluster will wait until the number of rebalancing operations affects less than this percentage of total data eligible for rebalancing. The default value is 10%.

4. Click **Save Changes** for the changes to take effect.

Enabling and Configuring Disk Balancer Using the CLI

About this task

The disk space balancer checks every storage pool on a regular basis and moves containers from a storage pool when that pool's utilization meets the following conditions:

- The storage pool is over 70% full.
- The storage pool's utilization exceeds the average utilization on the cluster by a specified threshold:
 - When the average cluster storage utilization is below 80%, the threshold is 10%.
 - When the average cluster storage utilization is below 90% but over 80%, the threshold is 3%.
 - When the average cluster storage utilization is below 94% but over 90%, the threshold is 2%.

You can use the `config save` command to modify disk space balancer parameter values.

Example: `# maprcli config save -values {"cldb.balancer.disk.max.switches.in.nodes.percentage":"20"}`

The following list specifies the disk space balancer configuration parameters with their default values and descriptions:

cldb.disk.balancer.enable

Default Value: 1

Description: Specifies whether the disk space balancer runs:

- 0 - Disabled (does not perform any container moves)
- 1 - Enabled (normal operation)

By default, the disk balancer is disabled.

cldb.balancer.disk.threshold.percentage

Default Value: 70

Description: Threshold for moving containers out of a given storage pool, expressed as utilization percentage.

See also: [Balancing Overused and Above Average Bins](#) on page 1331.

cldb.balancer.disk.max.switches.in.nodes.percentage

Default Value: 10

Description: This can be used to throttle the disk balancer. If it is set to 10, the balancer will throttle the number of concurrent container moves (minimum 1) to 10% of the total nodes in the cluster rounded up.

See [Configuring Throttling](#) on page 1332.

Configuring Disk Balancer Execution

Explains how to tune the disk balancer execution parameters.

Even when the disk balancer is enabled, the disk balancer waits during cluster startup to give enough time for the cluster to settle down. The default wait time (specified in seconds) is 30 minutes and can be changed using the parameter `cldb.balancer.startup.interval.sec`. After every run, the disk balancer pauses for 2 minutes by default. The pause time (specified in seconds) can be increased through the parameter `cldb.balancer.disk.sleep.interval.sec`.

Run the `maprccli config save` command and set the following parameters to configure disk balancer:

Parameter	Default Value	Description
<code>cldb.balancer.startup.interval.sec</code>	1800 seconds	Wait time, in seconds, for cluster startup.
<code>cldb.balancer.disk.sleep.interval.sec</code>	120 seconds	Interval, in seconds, between disk balancer runs.

For example, to:

- Increase the wait time to an hour, change the default value of 1800 seconds to 3600 seconds:

```
maprccli config save -values {"cldb.balancer.startup.interval.sec":"3600"}
```

- Increase the pause time between disk balancer runs from 2 minutes to 5 minutes, change the default value of 120 seconds to 300 seconds:

```
maprccli config save -values {"cldb.balancer.disk.sleep.interval.sec":"300"}
```

Preventing Volume Skew

By default, the disk balancer does not consider volume skew while moving containers out of a Storage Pool (SP). In the process, all containers of a volume may end up on only a few SPs. Such a volume skew is undesirable, specifically, for DB volumes. In such a skew, few servers handle all requests, resulting in reduced performance.

To prevent volume skew, set the `prevent.volume.skew.by.diskbalancer` parameter to `true` as follows:

```
maprcli config save -values {"prevent.volume.skew.by.diskbalancer":"true"}
```

This parameter checks whether moving a container out of a SP causes a volume skew elsewhere.

NOTE: Enabling this parameter may result in containers failing the volume underweight check and failing to be moved from a full SP. Consider this limitation and enable as per your need.

Configuring Bin Size

Explains how to configure the sizes of the various bins used by the disk balancer.

The number of bins used by the disk balancer is not constant and is determined by the sizes of different bins. You can configure the size of each of the bins (Below Average, Average, Above Average, and Overused) individually at run time. The larger the size of the bins, the greater the chance that two SPs that are in the vicinity of each other with respect to utilization fall in the same bin.

The default size of overused bins is only 3%, because SPs in this bin must be balanced at a finer granularity. The default size of above average, average, and below average bins is 20%. You can aggressively balance the storage pools across bins by reducing the size of each bin, forcing the SPs to fall into different bins. To reduce the size of each bin, specify the value for the following parameters using the `maprcli config save` command:

Parameter	Description
<code>dbal.above.avg.bin.size</code>	Specifies the bin size (%) of SPs whose usage is above the cluster average. The default is 20%.
<code>dbal.avg.bin.size</code>	Specifies the bin size (%) of SPs whose usage is in the average range. The default is 20%.
<code>dbal.below.avg.bin.size</code>	Specifies the bin size (%) of SPs whose usage is below the cluster average. The default is 20%.
<code>dbal.overused.bin.size</code>	Specifies the bin size (%) of SPs whose usage is in the overused range. The default is 3%.

For example, to reduce the size of the Below Average bin to 10%, run the following command:

```
maprcli config save -values {"dbal.below.avg.bin.size":"10"}
```

Balancing Overused and Above Average Bins

Describes how to balance highly utilized Overused and Above Average bins.

Storage pools in the Overused and Above Average bins are highly utilized. The default threshold of “overused” is 90%, which means that the first overused bin's lower bound is 90%. You should in normal circumstances, never reset this threshold, but you can, if necessary, by setting the value for the parameter `cldb.balancer.disk.overused.threshold` using the `maprcli config save` command. For example:

```
maprcli config save -values {"cldb.balancer.disk.overused.threshold":"95"}
```

In scenarios where the cluster average is low, storage pools in Above Average bins too might not be highly utilized. In this case, to prevent unnecessary balancing activity, disk balancer uses an additional criterion to prevent wasted moves: only those storage pools whose utilization equals to or is greater than a certain threshold are considered for balancing. This threshold is controlled by the configurable parameter `cldb.balancer.disk.threshold.percentage`, whose default value is 70%.

NOTE: If the threshold of the Overused bin is set below the default value of 90%, the balancing threshold specified in the `cldb.balancer.disk.threshold.percentage` parameter is also applicable to Overused bins also.

Balancing Average and Below Average Bins

Provides an overview of how the disk balancer balances the Average and Below Average storage pool bins.

The primary task of the disk balancer is to balance highly utilized storage pools in Overused and Above Average bins. However, the disk balancer can also balance storage pools that are less utilized, for example, to distribute workload evenly across the nodes, or if a new node is added to the topology to add more storage. By default, the disk balancer performs this kind of balancing less frequently than the balancing of disk space utilization.

By default, the disk balancer balances storage pools in Average and Below Average bins every 6 hours. You can configure the interval by the setting the value (in minutes) for the parameter `dbal.below.avg.bins.balancing.frequency` using the `maprcli config save` command. For example:

```
maprcli config save -values
{"dbal.below.avg.bins.balancing.frequency":"360"}
```

NOTE: The disk balancer considers storage pools in these two bins only under the following conditions:

1. When there is not already too much SP balancing activity in the highly utilized bins.
2. If container movement out of SPs in the highly utilized bins is not possible.

Configuring Throttling

Explains how to throttle the number of container moves.

Although balancing storage pool disk space use is important, it requires network, computation, and disk bandwidth that must be shared with other functions. Hence, the number of container moves at any point of time is throttled.

The throttling factor controls the number of active container moves. If there are 100 nodes, and the throttling factor is 10, there can be 10 active moves. If however, the value is 12 (%), there can be 12 active moves.

NOTE: If you set the throttling factor to 0, the number of active moves is 1.

Therefore, effectively, the number of active moves is:

```
Max(1, throttling_factor x number_of_cluster_nodes)
```

By default, the maximum number of container moves is 10% of the number of nodes in the cluster. However, you can configure the throttling factor (percentage) by setting the parameter `cldb.balancer.disk.max.switches.in.nodes.percentage` using the `maprcli` command.

For example, to set the throttling factor to 12% of the number of nodes in the cluster, run the following command:

```
maprcli config save -values
{"cldb.balancer.disk.max.switches.in.nodes.percentage":"12"}
```

Retrieving Status of Storage Pools

Describes the CLI command to retrieve the status of Storage Pools.

You can use the `maprcli dump balancerinfo` command to view detailed information about the Storage Pools on a cluster.

Example:

```
# maprcli dump balancerinfo
usedMB  fsid          spid          percentage
outTransitMB  inTransitMB  capacityMB
209      5567847133641152120  01f8625ba1d15db7004e52b9570a8ff3  1
0          0          15200
209      1009596296559861611  816709672a690c96004e52b95f09b58d  1
0          0          15200
```

If there are any active container moves when you run the command, `maprcli dump balancerinfo` returns information about the source and destination storage pools:

```
# maprcli dump balancerinfo -json
{
  "containerid":7840,
  "sizeMB":15634,
  "From fsid":8081858704500413174,
  "From IP:Port":"10.50.60.64:5660-",
  "From SP":"9e649bf0ac6fb9f7004fa19d200abcde",
  "To fsid":3770844641152008527,
  "To IP:Port":"10.50.60.73:5660-",
  "To SP":"fefcc342475f0286004fad963f0fghij"
}
```

Retrieving Balancer Status

Describes how to view the active container movement information from the Control Panel and the CLI.

You can view the active container moves information from the [CLDB page](#) on the Control Panel or use the `maprcli dump balancermetrics` command to see a cumulative count of container moves and MB of data moved between storage pools since the current CLDB became the primary CLDB.

Example:

```
# maprcli dump balancermetrics -json
{
  "timestamp":1337770325979,
  "status":"OK",
  "total":1,
  "data":[
    {
      "numContainersMoved":10090,
      "numMBMoved":3147147,
      "timeOfLastMove": "Wed May 23 03:51:44 PDT 2012"
    }
  ]
}
```

Viewing the List of Active Container Moves

Explains how to view the list of containers being moved, from the CLDB page.

About this task

Procedure

- Log in to the Control System and go to the [service information page](#) for CLDB.

The **Active Container Moves** section displays the following fields:

Container ID	The ID of the container being moved.
SizeMB	The size (in MB) of the container being moved.
From Location	The location from where the container is being moved.
From SP	The Storage Pool (SP) out of which the container is being moved.
To Location	The location to which the container is being moved.
To SP	The SP to which the container is being moved.

Volume Balancer

Describes the role of the volume balancer.

Volume balancer is used to distribute containers of a volume on all the storage pools that belong to the volume's topology. Although the disk balancer balances containers across storage pools, sometimes containers of a volume may accumulate on a few storage pools. For example:

- When the storage pools hosting a volume's containers are not highly utilized, the disk balancer might not spread the volume's containers across storage pools.
- When new storage pools are added to a topology and the storage pools on which the current containers reside are not highly utilized, although the disk balancer moves containers to new storage pools, it is not guaranteed that a specific volume's containers are evenly spread out.

In such cases, you can trigger the balancing of a volume using a `maprc li` command. Every time a volume gets out of balance, you can trigger the volume balancer (using the `maprc li` command) to balance the containers associated with the volume. The container moves triggered by disk and volume balancers do not cause other volumes to be imbalanced.

NOTE: If both disk balancer and volume balancer are triggered at the same time, volume balancer activity takes precedence.

Managing Volume Balancer

Explains the CLI commands that you can use to balance the containers of a volume.

Enabling and Disabling the Volume Balancer

About this task

The volume balancer is disabled by default. To enable or disable the volume balancer:

Procedure

- Set the value for the `cldb.volume.balancing.enable` parameter using the `config save` on page 2394 command. To:
 - Enable volume balancer, run the following command:

```
maprc li config save -values {cldb.volume.balancing.enable:1}
```

- Disable volume balancer, run the following command:

```
maprc li config save -values {cldb.volume.balancing.enable:0}
```

After enabling the volume balancer feature, you must run the `volume balancecontainers` on page 2922 command to balance the containers associated with a volume.

Balancing the Containers of a Volume

Procedure

- Run the `maprcli volume balancecontainers` command to balance a volume.
The basic command to balance a volume is:

```
/opt/mapr/bin/maprcli volume balancecontainers -name <vol_name>
```

For more information, see [volume balancecontainers](#) on page 2922.

Stopping the Volume Balancer**Procedure**

- Run the `maprcli volume balancecontainers` command to stop or cancel a balancing activity.
The command to cancel a volume balancer is:

```
/opt/mapr/bin/maprcli volume balancecontainers -name <vol_name> -cancel true
```

For more information, see [volume balancecontainers](#) on page 2922.

[config save](#) on page 2394

Saves configuration information, specified as key/value pairs. Permissions required: fc or a.

[volume balancecontainers](#) on page 2922

Balances the containers, or stops the balancing of containers associated with the volume.

Retrieving Balancer Status

Retrieve the status of a balancer activity using the CLI.

Procedure

Run the `maprcli volume balancinginfo` command to retrieve the status of a currently running or scheduled balancer activity.

The basic command to retrieve the status of volume balancer is:

```
/opt/mapr/bin/maprcli volume balancinginfo -name <vol_name>
```

For more information, see [volume balancinginfo](#) on page 2923. For example:

```
# /opt/mapr/bin/maprcli volume balancinginfo -name Volume1 -json
{
  "timestamp":1502529117881,
  "timeofday":"2017-08-12 09:11:57.881 GMT+0000",
  "status":"OK",
  "total":5,
  "data":[
    {
      "volumeName":"Volume1"
    },
    {
      "isBalancingInProgress":false
    },
    {
      "numContainers":15
    },
    {

```

```

    "volumeSize":384
  },
  {
    "spInfo":[
      {
        "spId":"f891ae9e6663fa2000598ec48808155c",
        "capacity":152969,
        "usedSize":96,
        "desiredSize":95,
        "isUnderweight":false,
        "isOverweight":false
      },
      {
        "spId":"bed92c0ecfaefc8b00598ec48b01cdfe",
        "capacity":152969,
        "usedSize":96,
        "desiredSize":95,
        "isUnderweight":false,
        "isOverweight":false
      },
      {
        "spId":"b61aa1b814fd8bbc00598ec48d0af1d2",
        "capacity":157065,
        "usedSize":96,
        "desiredSize":97,
        "isUnderweight":false,
        "isOverweight":false
      },
      {
        "spId":"7af11d5b9d223baa00598ec4850efb57",
        "capacity":152969,
        "usedSize":96,
        "desiredSize":95,
        "isUnderweight":false,
        "isOverweight":false
      }
    ]
  }
]
}

```

Replication Role Balancer

Describes the features of the replication role balancer.

The replication role balancer manages containers to optimize the following:

- Network bandwidth during the replication process
- Disk I/O and CPU when serving read requests

The replication role balancer switches the replication roles of name and data containers to balance them across each storage pool in a volume. You can modify the `cldb.role.balancer.strategy` parameter from the `maprccli` to change how the role balancer manages the containers, either by size or count. You can also run the `dump rolebalancerinfo` command to see the status of active role switches or how container roles are balanced across each storage pool for a particular volume.

Replicated Containers

The name container is the first container created in every volume. Name containers can have either a *primary* or a *replica* role. Data containers can have a *primary*, *intermediate*, or *tail* role. By default, each name and data container is replicated across the cluster three times, with the primary being the first container written. The primary is sequentially replicated two more times, into a container with either an intermediate or a tail container role. If too many primary or intermediate containers exist on a storage pool or if the primary and intermediate containers are too large, the role balancer switches some of these containers to tail containers.

By default, the role balancer compares the size of the primary and tail containers to determine if containers within a storage pool are balanced. For the best performance, the size of the primary containers in a volume should be evenly distributed across storage pools. The role balancer maintains this balance by ensuring that each type of container (primary, intermediate, and tail) accounts for $1/\text{ReplicationFactor}$ of the total container size in a volume.

If the role balancer is configured to manage containers by count, it compares the number of primary and tail containers and balances the roles such that each type of container accounts for $1/\text{ReplicationFactor}$ of the total number of containers in a volume. For example, if the replication factor is set to 3, the role balancer maintains a balance of primary, intermediate, and tail containers in each volume.

HPE Data Fabric Database Considerations

To optimize HPE Data Fabric Database performance, you should configure the role balancer to manage containers by size. As described at [HPE Data Fabric Database and File Store](#) on page 707, HPE Data Fabric Database shards tables into *tablets* and stores the tablets in data containers. Only primary data containers serve reads. Therefore, configuring the role balancer by size spreads read requests evenly across the storage pools for a volume. To ensure the most optimal balancing for your HPE Data Fabric Database tables, you should consider storing them on dedicated volumes.

Assign Cache

The assign cache is a list of reserved containers on a particular file server node that are allocated by the CLDB (container location database). The replication role balancer does not balance the containers in the assign cache and does not include them when balancing the roles. See the [maprccli dump rolebalancerinfo](#) command for assign cache values and details.

Enabling and Configuring Replication Role Balancer

Describes how to use the Control System or the CLI to enable and configure the Replication Role Balancer.

Enabling and Configuring the Replication Role Balancer Using the Control System

About this task

Procedure

1. Log in to the Control System and click **Admin > Cluster Settings > Balancer**.
2. From the Role Balancer section, set the **Enabled** slider to **Yes**.
3. Select one of the presets or specify a custom value for the **Concurrent Role Rebalancer** and **Delay for Active Data in Seconds** settings. You can choose:
 - Presets:

Default

- **Concurrent Role Rebalancer** — 20%
- **Delay for Active Data in Seconds** — 600 sec

Rapid

- **Concurrent Role Rebalancer** — 5%
- **Delay for Active Data in Seconds** — 300 sec

Moderate

- **Concurrent Role Rebalancer** — 10%
- **Delay for Active Data in Seconds** — 600 sec

Relaxed

- **Concurrent Role Rebalancer** — 25%
- **Delay for Active Data in Seconds** — 1800 sec

- **Custom**, use the slider to set the concurrent role rebalancer percentage and delay for active data in seconds.

Here:

Concurrent Role Rebalancer	Specifies the maximum percentage of data affected by concurrent role rebalancer operations. The cluster will wait until the number of rebalancing operations affects less than this percentage of total data eligible for rebalancing.
Delay for Active Data in Seconds	At the time of calculation, the role rebalancer will skip any data that is active within this time interval. This prevents unnecessary tampering with data used in recent or ongoing computations.

4. Click **Save Changes** for the changes to take effect.

Enabling and Configuring Replication Role Balancer Using the CLI

About this task

You can use the `config save` command to modify the replication role balancer parameter values.

Example: `# maprcli config save -values {"cldb.role.balancer.strategy":"BySize"}`

The following table lists the replication role balancer configuration parameters with their default values and descriptions:

Parameter	Value	Description
cldb.balancer.role.paused	1	Specifies whether the role balancer runs: <ul style="list-style-type: none"> • 0 - Not paused (normal operation) • 1 - Paused (does not perform any container replication role switches)
cldb.role.balancer.strategy	"BySize"	Specifies how the replication role balancer balances containers, either by size or count. Use "BySize" or "ByCount" to indicate how role balancer balances containers.

Parameter	Value	Description
cldb.balancer.role.max.switches.in.no des.percentage	10	This can be used to throttle the role balancer. If it is set to 10, the balancer will throttle the number of concurrent role switches to 10% of the total nodes in the cluster (minimum 2).

Retrieving Role Balancer Status Using the CLI

Lists the CLI command to view the number of active replication role switches.

About this task

You can use the `maprcli dump rolebalancerinfo` command to view the number of active replication role switches. During a replication role switch, the replication role balancer selects a primary or intermediate data container and switches its replication role to that of a tail data container.

Example

Example:

```
# maprcli dump rolebalancerinfo -json
{
  "timestamp":1335835436698,
  "status":"OK",
  "total":1,
  "data":[
    {
      "containerid": 36659,
      "Tail IP:Port":"10.50.60.123:5660-",
      "Updates blocked Since":"Wed May 23 05:48:15 PDT 2012"
    }
  ]
}
```

Managing Licenses

Provides a synopsis of adding licenses using the Control System and the CLI.

You can add and remove licenses on your cluster using the Control System or the CLI:

- In the Control System, go to **Admin > Cluster Settings > Licenses**.
- On the command line, use the `maprcli license` commands.

WARNING: Remove old licenses from the cluster when you add a new license. If multiple licenses exist, the cluster activates only the license with the lowest node count.

Adding a License

Add a license through the Control System or the CLI.

Adding a License Using the Control System

About this task

Complete the following steps to add a license using the Control System:

Procedure

1. On a machine that is connected to the cluster and to the Internet, perform the following steps to open the Control System:

- a) In a browser, view the Control System by navigating to the node that is running the Control System: `https://<webserver>/:8443`.
Your computer will not have a HTTPS certificate yet, so the browser will warn you that the connection is not trustworthy. You can ignore the warning this time.
- b) Log in to the Control System as the administrative user you designated earlier.
Until a license is applied, the Control System dashboard might show some nodes in the amber "degraded" state. Do not worry if not all nodes are green and "healthy" at this stage.

2. In the Control System, go to **Admin > Cluster Settings > Licenses**.

3. Add a license using the following options:

Import License	Allows you to import a license from the server. You must enter your credentials in the Import License window to retrieve your license information.
Upload License	Allows you to upload your license file through a browser.
Copy/Paste License	Allows you to copy and paste a license key in the Copy and Paste License window.
Get a Free Trial License	Navigates to the HPE Data Fabric licensing form online to get a trial license.

4. Click **Submit**.

If the cluster is already registered, the license is applied automatically. Otherwise, go to hpe.com and follow the instructions there to register the cluster.

Adding a License Using the CLI or the REST API

About this task

To add a license from the CLI:

Procedure

1. Obtain a valid license file from HPE Data Fabric.
2. Copy the license file to a cluster node.
3. Run the following command to add the license:

```
maprcli license add [ -cluster <name> ] -license <filename> -is_file true
```

See [license add](#) on page 2541 for complete reference information.

Related concepts

[Upgrading and Your License](#) on page 460

You do not need a new license to upgrade an HPE Data Fabric cluster. However, it's a good idea to check your cluster license periodically and renew the license before it expires.

Viewing the Licenses on the Cluster

List the licenses on the cluster using either the Control System or the CLI.

Viewing the Licenses Using the Control System

About this task

To view licenses:

Procedure

1. Log in to the Control System.
2. Click **Admin > Cluster Settings > Licenses**.

Under **LICENSES**, the pane displays the following information for each license:

Column Name	Column Description
Active	Indicates whether (✓) the license is active.
Grace	Denotes the remaining grace period (in days) before which you must renew the expired license.
Name	The name of the license.
Module/Type	The type of license.
Issued	The date the license was issued.
Expires	The license expiration date.
Nodes	The number of nodes to which the license applies.
Delete	The option to remove the license.

You can:

- [Add](#) a license
- [Remove](#) a license

*Viewing the Licenses Using the CLI or REST API***About this task**

The basic command to get a list of licenses on the cluster is:

```
maprcli license list -cluster <cluster>
```

Removing a License

Describes how to remove a license using the Control System and the CLI.

Removing a License Using the Control System

About this task

To remove a license:

Procedure

1. Log in to the Control System and click **Admin > Cluster Settings > Licenses**.
2. Click the **Delete** link associated with the license to display the **Remove License** confirmation dialog.
3. Click **Submit** to remove the license.

*Removing a License Using the CLI or REST API***About this task**

To remove a license on a cluster:

Procedure

1. From the command line, issue the `maprccli license list` on page 2545 command. Example:
`maprccli license list`
2. Look for the `id` parameter in the output from the license list command.
This is the license ID. Example:

```

  grace id                        description      deletable license
  maxnodes
  true  5CTFWAeQQUIOc5Wm/ono0JqcCls MapR Base Edition false
        version: "1.0"
        customerid: "BaseLicenseUser"
        issuer: "MapR Technologies, Inc."
        licType: Base
        description: "MapR Base Edition"
        ...

```

3. Use the `maprccli license remove` on page 2548 command to remove the license.
Example:

```
maprccli license remove -license_id 5CTFWAeQQUIOc5Wm/ono0JqcCls
```

Setting Quota Defaults for Users and Groups

Explains how to set disk space quotas for users and groups.

About this task

Quotas limit the disk space used by a volume or an *entity* (user or group) on a licensed cluster, by specifying the amount of disk space the volume or entity is allowed to use. A volume quota limits the space used by a volume. A user or group quota limits the space used by all volumes owned by a user or group. These quotas work on tenant volumes as well.

You can set hard quota and advisory quota defaults for users and groups. When a user or group is created, the default quota and advisory quota apply unless overridden by specific quotas. You can set an entity quota that differs from the default using the [entity modify](#) on page 2481 command or through the Control System.

The size of a disk space quota is expressed in terms of the actual data stored from the user's point of view. Only post-compression data blocks are counted. Snapshot and replica space do not count against quotas. For example, a 10G file that is compressed to 8G and has a replication factor of 3 consumes 24G (3*8G), but charges only 8G to the user or volume quota.

You can set an entity quota through the Control System and by using the CLI.

Setting Quotas Using the Control System

About this task

Complete the following steps to set the entity quota in the Control System:

Procedure

1. Go to **Admin > Cluster Settings > Quotas**.

2. Set the advisory and hard quotas for the:

- User under **USER QUOTA**.
- Group under **GROUP QUOTA**.

A hard quota prevents writes above the specified threshold. An advisory quota does not enforce disk usage limit, but raises an alarm when the specified threshold is exceeded:

- `AE_ALARM_AEADVISORY_QUOTA_EXCEEDED` - an entity exceeded its advisory quota
- `VOLUME_ALARM_ADVISORY_QUOTA_EXCEEDED` - a volume exceeded its advisory quota

In most cases, it is useful to set the advisory quota a little lower than the hard quota, to give advance warning that disk usage is approaching the allowed limit.

3. Set the cluster reserve limit, which is the amount of disk space that you wish to allocate for all volumes on the cluster.

When you set a reserve limit, you provision a certain amount of space to the volumes as a percentage of the cluster capacity. This allows you to free up space that could potentially be unused, or allocate more space for replication.

As data is written to the volume, available space is automatically allocated. The volume reserve increases up to the reserve limit you set here.

4. After setting the quota, click **Save** to save the settings.

Setting Entity Quotas Using the CLI or the REST API

About this task

To set an entity (user or group) quota, run the following command:

```
maprcli entity modify -name <entityname> -advisoryquota <advisory
quota> -quota <quota>
```

To manage quotas, you must have a or fc permissions.

Quotas are expressed as an integer value plus a single letter to represent the unit:

- B - bytes
- K - kilobytes
- M - megabytes
- G - gigabytes
- T - terabytes
- P - petabytes

Example: 500G specifies a 500-gigabyte quota. Do not use two-letter abbreviations (for example, MB or GB) for units.

For complete reference information, see the [entity modify](#) on page 2481 command.

Setting the Cluster Reserve Limit Using the CLI or REST API

About this task

To set the resource usage limit for the cluster disk resource, run the following command:

```
maprcli rlimit set -resource disk -cluster <cluster name> -value <limit>
```

For complete reference information, see the [rlimit set](#) on page 2613 command.

Related reference

[entity modify](#) on page 2481

Modifies a user or group quota or email address. Permissions required: fc or a.

[rlimit set](#) on page 2613

Sets the resource usage limit for the cluster's disk resource.

Specifying the Location of Gateways

Describes how to set the location of the HPE Data Fabric gateways using either the Control System or the CLI.

About this task

On every source HPE Data Fabric cluster, you can specify the location of the gateways by adding a DNS record to your DNS server's zone file for your domain. In your DNS server's zone file for your domain, add a record for the cluster where gateways are located, listing the nodes to use as gateways. You can use the Control System to create a record that you can copy into a DNS configuration file, run a `maprcli` command to generate the record, or create a record manually. For more information on gateways, see [Managing Gateways](#) on page 1791.

Specifying the Location of Gateways Using the Control System

About this task

To create a record using the Control System, follow these steps:

Procedure

1. Log in to the Control System on the cluster where the gateways are located.
2. Click **Admin > Cluster Settings > Gateway**.
3. Click **Copy to Clipboard** to copy the generated DNS entry.
4. Paste the record into your zone file.

Specifying the Location of Gateways Using the CLI

About this task

To generate a record by using the `maprc li` command, follow these steps:

Procedure

1. On the cluster where the gateways are located, run the following command.

```
maprc li cluster gateway local -format dns
```

If you want to run the command from a different cluster and point to the cluster that hosts the gateways, use the `-cluster` parameter to provide the name of the latter cluster.

2. Copy and paste the output of this command into your zone file.

Creating a Record Manually

About this task

If you want to create a record manually, use this format:

```
gateway.<clustername> IN TXT "<space-delimited list of hostnames>"
```

You can also specify IP addresses, though using hostnames is recommended so that it is easier to locate gateways if their IP addresses change. Combinations of hostnames and IP addresses are also supported. The default port is 7660. If a gateway is using a different port, append a colon to the address and then specify the port number. Here is an example entry:

```
gateway.newyork.bigcompany.com gw1ny.bigcompany.com gw2ny.bigcompany.com
```

Multi-homing is also supported. Simply separate the entries for a single node with semicolons, as in this example that uses IP addresses:

```
gateway.newyork.bigcompany.com 10.10.34.20 10.10.34.22
10.10.34.24;173.194.79.121
```

Managing Alarms

You can view all the alarms and configure settings, including severity and notifications, on the Control System and using the CLI.

Viewing the List of Alarms

Specifies how to view the list of alarms raised, using either the Control System or the CLI.

About this task

You can view all the alarms on the Control System and using the CLI.

Viewing the List of Alarms in the Control System

Procedure

1. Log in to the Control System and click **Admin > Cluster Settings > Alarms**.
The **ALL ALARMS** pane displays all the alarms on the cluster.
2. Select:

- **Cluster Alarms** — indicate problems that affect the cluster as a whole
- **Node Alarms** — indicate problems on individual nodes
- **Table Alarms** — indicate table replication-related problems
- **User/Group Alarms** — indicate problems with user or group quotas
- **Volume Alarms** — indicate problems in individual volumes

For the selected view, the pane displays the following for each alarm:

Column Name	Column Description
Alarm Name	The name of the alarm.
Severity	The user-defined severity for the alarm.
Description	A one-line description of the alarm.
Info	Information on the alarm including alarm name, description, and recommended action to address the alarm.

You can click the alarm name to [configure alarm settings](#).

Retrieving the List of Alarms Using the CLI or REST API

About this task

The basic command to list all alarms by type (Cluster, Node, User, or Volume) is:

```
maprcli alarm list -type (cluster|node|volume|AE)
```

For complete reference information, see [alarm list](#) on page 2298.

Configuring Alarm Settings

Set the severity and notifications for each alarm using either the Control System or the CLI.

About this task

Configuring Alarm Settings Using the Control System

About this task

To configure alarm setting from the Control System:

Procedure

1. Log in to the Control System and click **Admin > Cluster Settings > Alarms**.
2. Select:
 - **Cluster Alarms** to configure settings for the alarms that affect the cluster as a whole
 - **Node Alarms** to configure settings for the alarms that indicate problems on individual nodes
 - **Table Alarms** to configure settings for the alarms that indicate table replication-related problems
 - **User Alarms** to configure settings for the alarms that indicate problems with user or group quotas
 - **Volume Alarms** to configure settings for the alarms that indicate problems in individual volumes
3. Click the name of the alarm to display the **Alarm Settings** window.

4. Specify a description of the alarm under **GENERAL** settings.
5. Configure alarm notifications (under **NOTIFICATIONS**) to allow HPE Data Fabric to send an email notification when the alarm is raised.
 - a) Select (to enable) or deselect (to disable) the **Email Notifications** checkbox.
 - b) If notifications are enabled, enter the user name or group name to which to send email when the alarm is raised, and click **Add**.
See [Setting Up SMTP](#) on page 1288 for additional information.
6. Click **Save Changes** to save your settings.

Configuring Alarm Settings Using the CLI or REST API

About this task

To set up alarm notifications, run the `alarm config save` command from the command line.

 **WARNING:** You must have `fc` (full control) or `a` (admin) permissions to run this command.

The format of the command is:

```
maprcli alarm config save -cluster <cluster_name> -values
"<alarm>,<enableEmail>,<email>"
```

Assign values as follows:

Value	Description	Example
alarm	Name of the alarm	DISK_FAILURE_ALARM
enableEmail	Specifies whether individual alarm notifications are sent to any email address (including the default email address) for the alarm type. <ul style="list-style-type: none"> 0 - do not send notifications to any email address for the alarm type 1 - send notifications to all email addresses for the alarm type 	1
email	One or more email addresses other than the default email address. If specified, alarm notifications are sent to these addresses as well, if <i>enableEmail</i> is set to 1. Multiple email addresses must be separated by spaces only. You cannot use commas or other delimiters. For example, <code>user1@mycorp.com user2@mycorp.com</code> is valid.	user1@mycorp.com

Configuring the Alarm Threshold Using the CLI

You can configure the alarm threshold for certain alarms. For the alarms that support threshold configuration, this topic describes the command to run to set the threshold.

VOLUME_ALARM_INODES_EXCEEDED

Threshold is configurable at both the cluster and the volume level.

If configured at both the cluster and volume levels, the volume level threshold overrides cluster-level threshold.

To configure at the cluster-level, run the following commands:

```
# /opt/mapr/bin/maprcli config
save -values
'{"cldb.max.inodes.volume.alarm.thresh
": "<value>"}'
# /opt/mapr/bin/maprcli config
save -values
'{"cldb.default.max.namespace.size.mb.
alarm.thresh": "<value>"}'
```

For example,

```
# /opt/mapr/bin/maprcli config
save -values
'{"cldb.max.inodes.volume.alarm.thresh
": "500000000"}'
# /opt/mapr/bin/maprcli config
save -values
'{"cldb.default.max.namespace.size.mb.
alarm.thresh": "512000"}'
```

To configure at the volume-level, run the following commands:

```
# /opt/mapr/bin/maprcli
volume modify -name
<volname> -maxinodesalarmthreshold
<threshold>
# /opt/mapr/bin/maprcli
volume modify -name
<volname> -maxnssizebalarmthreshold
<threshold>
```

For example,

```
# /opt/mapr/bin/maprcli
volume modify -name
testvol -maxinodesalarmthreshold 0
# /opt/mapr/bin/maprcli
volume modify -name
testvol -maxnssizebalarmthreshold 0
```

VOLUME_ALARM_TOPOLOGY_ALMOST_FULL

Threshold is configurable at cluster level.

To configure, run the following command:

```
# /opt/mapr/bin/maprcli config
save -values
'{"cldb.topology.almost.full.percentag
e": "<value>"}'
```

For example,

```
# /opt/mapr/bin/maprcli config
save -values
```

```
'{"cldb.topology.almost.full.percentag
e":"90"}'
```

VOLUME_ALARM_QUOTA_EXCEEDED

Threshold is configurable in volume properties.

To configure, run the following command:

```
# /opt/mapr/bin/maprccli volume
modify -name <volname> -quota <value>
```

For example,

```
# /opt/mapr/bin/maprccli volume
modify -name testvol -quota 204800
```

VOLUME_ALARM_TABLE_INDEX_LAG_HIGH

Threshold is configurable in volume properties.

To configure, run the following command:

```
# /opt/mapr/bin/maprccli
volume create -name
<volname> -dbindexlagsecalarmthresh
<value in seconds>
```

For example,

```
# /opt/mapr/bin/maprccli
volume create -name
testvol -dbindexlagsecalarmthresh 60
```

VOLUME_ALARM_TABLE_REPL_LAG_HIGH

Threshold is configurable in volume properties.

To configure, run the following command:

```
# /opt/mapr/bin/maprccli
volume create -name
<volname> -dbrepllagsecalarmthresh
<value in seconds>
```

For example,

```
# /opt/mapr/bin/maprccli
volume create -name
testvol -dbrepllagsecalarmthresh 50
```

VOLUME_ALARM_ADVISORY_QUOTA_EXCEEDED

Threshold is configurable in volume properties.

To configure, run the following command:

```
# /opt/mapr/bin/maprccli volume
modify -name <volname> -advisoryquota
<value>
```

For example,

```
# /opt/mapr/bin/maprccli volume
modify -name testvol -advisoryquota
450
```

VOLUME_ALARM_LABEL_ALMOST_FULL

Threshold is configurable at cluster level.

```
# /opt/mapr/bin/maprcli config
save -values
'{"cldb.label.almost.full.percentage":
"<value>"}
```

For example,

```
# /opt/mapr/bin/maprcli config
save -values
'{"cldb.label.almost.full.percentage":
"90"}
```

The default value is 90% which means that this alarm is raised when the free storage space on Storage Pools/Nodes with the desired label for container creation/replication is down to 10% of the total storage space with the desired label.

AE_ALARM_AEQUOTA_EXCEEDED

Threshold is configurable in ae properties.

```
# /opt/mapr/bin/maprcli entity
modify -name <entityname> -type
<type> -quota <value>
```

For example,

```
# /opt/mapr/bin/maprcli entity
modify -name newuser -type 0 -quota 0
```

NOTE: The value, 0, for the type parameter in the above example represents the user entity type.

AE_ALARM_AEADVISORY_QUOTA_EXCEEDED

Threshold is configurable in ae properties.

```
# /opt/mapr/bin/maprcli entity
modify -name <entityname> -type
<type> -advisoryquota <value>
```

For example,

```
# /opt/mapr/bin/maprcli entity
modify -name newuser -type
0 -advisoryquota 0
```

NOTE: The value, 0, for the type parameter in the above example represents the user entity type.

NODE_ALARM_TOO_MANY_CONTAINERS

Threshold is configurable at cluster level.

This alarm is also raised when total number of containers (including snap containers) exceed 10 times the value of `pernode.numcntrs.alarm.thr`.

```
# /opt/mapr/bin/maprcli config
save -values
'{"pernode.numcntrs.alarm.thr": "<value>"}
```

For example,

```
# /opt/mapr/bin/maprcli config
save -values
'{"pernode.numcntrs.alarm.thr":"50000"}'
```

NODE_ALARM_NO_HEARTBEAT

Threshold is configurable at cluster level.

```
# /opt/mapr/bin/maprcli config
save -values
'{"cldb.fs.mark.inactive.sec": "<value>"}'
```

For example,

```
# /opt/mapr/bin/maprcli
config save -values
'{"cldb.fs.mark.inactive.sec": "10"}'
```

NODE_ALARM_HIGH_MFS_MEMORY

Threshold is configurable at cluster level.

This alarm is raised when file system memory consumption exceeds the threshold.

```
# /opt/mapr/bin/maprcli config
save -values
'{"mfs.high.memory.alarm.threshold": "<value>"}'
```

For example,

```
# /opt/mapr/bin/maprcli config
save -values
'{"mfs.high.memory.alarm.threshold": "110"}'
```

CLUSTER_ALARM_CLUSTER_ALMOST_FULL

Threshold is configurable at cluster level.

```
# /opt/mapr/bin/maprcli config
save -values
'{"cldb.cluster.almost.full.percentage": "<value>"}'
```

For example,

```
# /opt/mapr/bin/maprcli config
save -values
'{"cldb.cluster.almost.full.percentage": "90"}'
```

CLUSTER_ALARM_LICENSE_NEAR_EXPIRATION

Threshold is configurable at cluster level.

```
# /opt/mapr/bin/maprcli config
save -values
'{"mapr.license.expiry.notificationdays": "<value>"}'
```

For example,

```
# /opt/mapr/bin/maprcli config
save -values
'{"mapr.license.exipry.notificationdays":"30"}'
```

CLUSTER_ALARM_TOO_MANY_SNAPSHOT_CONTAINERS

Threshold is configurable at the cluster level by setting the value for the `cldb.snap.cntr.count.alarm.threshold` property in the `cldb.conf` file. See [cldb.conf](#) on page 3358 for more information.

NOTE: The default value is 100000000.

Viewing Alarm Information

Describes how to view alarm information using the Control System.

About this task

You can view notes for an alarm in the Control System.

Viewing Alarm Information in the Alarms Page

Procedure

1. Log in to the Control System and click **Admin > Cluster Settings > Alarms**.
2. Select:
 - **Cluster Alarms** to view notes for the alarms that affect the cluster as a whole
 - **Node Alarms** to view notes for the alarms that indicate problems on individual nodes
 - **Table Alarms** to view notes for the alarms that indicate table replication-related problems
 - **User Alarms** to view notes for the alarms that indicate problems with user or group quotas
 - **Volume Alarms** to view notes for the alarms that indicate problems in individual volumes
3. Click  associated with the alarm in the **Info** column.
The **Alarm Information** window displays a description of the alarm and the recommended action to address the alarm.

Viewing Alarm Information in the Active Alarms Pane

Procedure

- Click  associated with the alarm in the **Active Alarms** pane to view information on the alarm.
The **Alarm Information** window displays a description of the alarm, type of alarm, information on the alarm, and recommended action to address the alarm.

Dismissing an Alarm

Describes how to dismiss an alarm, either manually or automatically, using either the Control System or the CLI.

About this task

You can dismiss an alarm using the Control System or the CLI. When you dismiss an alarm, it will be cleared. You can raise the alarm again:

- Manually using the CLI
- Automatically when the conditions for raising the alarm again are met

*Dismissing Alarm(s) Using the Control System***About this task**

The **Dismiss** action is available in all the **Active Alarms** pane and in the **Alarms Summary** page. To dismiss alarm(s):

Procedure

1. Click **Dismiss**.

The **Dismiss Alarms** dialog displays.

2. Verify the alarm(s) to dismiss and click **Dismiss** to dismiss the alarm(s).

*Dismissing Alarm(s) Using the CLI***About this task**

The basic command to dismiss an alarm is:

```
maprcli alarm clear -alarm <alarm>
```

For complete reference, see [alarm clear](#) on page 2283.

Muting and Unmuting Alarms

Describes how to mute and unmute alarms using either the Control System or the CLI.

About this task

You can mute (silence) one or more (non-critical) alarms for a specific period of time using either the Control System or the CLI. The alarm will be silenced for the duration of the mute period and CLDB will raise the alarm again after the mute period **only** if the conditions for raising the alarm instance again are met.

*Muting Alarm(s) Using the Control System***About this task**

The **Mute** action is available in all the **Active Alarms** pane and in the **Alarms Summary** page. To mute alarm(s):

Procedure

1. Click **Mute** to display the **Mute Alarms** dialog.
2. Verify the alarm(s) to mute.
3. Select the period of time (1 hour, 6 hours, or 24 hours) to mute the alarm for from the **Mute Alarms for** drop-down list.

4. Click **Mute Alarms to mute the alarm(s).**

The alarm will be raised again if the associated issue is not resolved within the specified period of time.

*Muting Alarm(s) Using the CLI***About this task**

The basic command to mute an alarm is:

```
maprcli alarm mute -alarm <alarm name>[:<entity>]:<mute_period>
```

For complete reference, see [alarm mute](#) on page 2303.

*Unmuting Alarm(s) Using the CLI***About this task**

The basic command to mute an alarm is:

```
maprcli alarm unmute
```

For complete reference, see [alarm unmute](#) on page 2309.

Working with Multiple Instances of the File System

The Multi-file system feature allows multiple instances of the file server to run on a single node in a single process.

Multiple instances of the Data Fabric file server can run on a single node in a single process with the installation of the HPE Data Fabric File Store, or the HPE Data Fabric Database software. On servers with SSDs with at least 2 storage pools (SP), two instances (per node) are configured by default. On servers without SSDs, a single instance is configured by default. Each instance runs as a separate library that is dynamically loaded into a single process. In this mode, each instance has a separate host ID; however, all the instances share the same hostname.

The maximum number of supported instances is 32. Instances should be configured based on the available CPU, memory, disks, and SPs. Each instance needs a minimum of 2GB, and instances should not exceed:

- Number of CPUs / 2
- Number of SPs (enforced)

File Server Instances

On File Store and HPE Data Fabric Database installations, nodes with SSDs can run multiple file server instances. To determine whether a node has SSDs, Data Fabric uses the value of `mfs.disk.is.ssd` in the [mfs.conf](#) on page 3373 file, which must be set to 1. Add this parameter to [mfs.conf](#) on page 3373, on a node that has SSDs.

For clusters with File Store or HPE Data Fabric Database license, if you set the `mfs.disk.is.ssd` in the [mfs.conf](#) on page 3373 file to 1, CLDB configures nodes with SSDs to have 2 file server instances by default. On homogeneous clusters, you can modify the number of instances by [changing](#) the value of the `multimfs.numspis.perinstance` parameter.

Ports for Multiple Instances of the file system

Each instance listens on its own set of ports. Ensure that the appropriate ports are open for this feature. For example, instance 0 will use four ports from 5660, 5692 (5660+32), 5724 (5660+64), and 5756 (5660+96), instance 1 will use four ports from 5661, 5693, 5725, 5757, and so on for every additional instance. The topology of all instances is the same.

The total number of instances depends on the number of MFS threads, as indicated by the parameter `mfs.numrpcthreads` in [mfs.conf](#) on page 3373.

To verify that these ports are open, run the following command from a remote machine:

```
mrconfig -i -h <ip> -p <port number> info threads
```

An error indicates that the port is not open. If a port (for example, port 5661) is blocked, this command prints something similar to the following:

```
-----
|From Instance 5661::|
-----
<...> rpc failed <...>
```

Host IDs for Multiple Instances of the file system

For multiple instances of the file system, do NOT add IDs manually, but let the system handle the host ID numbering.

Log Files

Each instance has its own set of log files in `$MAPR_HOME/Logs`. When multiple instances are configured, the log files have the same name with a different instance ID; for example, `mfs.log.<N>-3` where N is the instance number.

NOTE: For the primary instance, the log file name does not include the instance number.

The RPC and security trace information are in a separate file per instance, `mfs-<N>.err`, where N is the instance number. For the primary instance, the file name does not include the instance number.

For example, suppose there are 2 instances running on ports 5660 and 5661. There are 2 sets of log files, one for each instance:

- `mfs.log-3` for the primary instance
- `mfs.log.1-3` for the second instance

The RPC and security trace information are present in the following files :

- `mfs.err` for the primary instance
- `mfs-1.err` for the second instance

Configuring the Number of Storage Pools per Instance

Describes how to set the number of storage pools for each file system instance, from the CLI.

About this task

As you add file system instances, Data Fabric assigns SPs to them. If file system instances are removed, the SPs assigned to those instances are re-allocated among the remaining live file system instances. By default, the value is 1, which implies that there is only 1 SP for all instances. You can re-configure the number of SPs per instance globally or at the node-level.

NOTE: If the number of file system instances is not as configured, the [Instance Mismatch Alarm](#) will be raised. If the alarm is raised on a:

- CLDB node, restart warden by running the following command:

```
service mapr-warden restart
```

- Non-CLDB node, restart file server by running the following command:

```
maprccli node services -nodes <node-ip> -fileserver restart
```

Global Configuration

About this task

If you configure globally, the configuration will be applied to all the nodes in the cluster. Make the following changes only on homogeneous clusters (that is, when all nodes in the cluster have the same type of disks and the stripe width of the disks is the same):

Procedure

1. Run the following commands:

```
maprccli config save -values {multimfs.numspcs.perinstance:3}
maprccli config save -values {multimfs.numinstances.pernode:2}
```

The default value of the `multimfs.numspcs.perinstance` parameter is 0. Suppose a node reports 9 SPs:

- For a value of 3, the node would need to start 3 instances.
- For a value of 5, the node would need to start 2 instances.

For clusters with fast SSDs, this can be set to 1.

NOTE: On AWS nodes with HDD, set the `multimfs.numspcs.perinstance` parameter value to 50 to use a single instance.

2. Restart Warden in every node for the configuration change to take effect.

Node-level Configuration

About this task

At the node level, you can configure different number of instances for each node in the cluster. To change the number of SPs per instance:

Procedure

1. Run the following command:

```
maprccli node modify -nodes <nodename> -numSpsPerInstance <n>
```

The number of instances changes automatically when new SPs are created.

2. Restart Warden on the nodes where the configuration has changed.

Monitoring Multiple Instances of the File System

Describes how to monitor the health and performance of your cluster.

Determining the Number of Running Instances

Procedure

- Run the following command to determine the number of instances actually running:

```
/opt/mapr/server/mrconfig info instances
```

Your output will look similar to the following. This output shows that two File Server instances are running on ports 5660 and 5661.

```
/opt/mapr/server/mrconfig info instances
2
5660 5661
```

Alternatively, on large clusters, run the following command to:

- Determine the number of configured instances:

```
maprcli node list -columns numInstances
hostname          numInstances  ip
atsqa4-161.qa.lab 1             10.10.88.161
atsqa4-162.qa.lab 1             10.10.88.162
atsqa4-163.qa.lab 1             10.10.88.163
atsqa4-164.qa.lab 1             10.10.88.164
```

- Determine the number of running instances reported by file system to CLDB:

```
maprcli node list -columns numReportedInstances
numReportedInstances hostname      ip
2                    atsqa4-161.qa.lab 10.10.88.161
1                    atsqa4-162.qa.lab 10.10.88.162
1                    atsqa4-163.qa.lab 10.10.88.163
2                    atsqa4-164.qa.lab 10.10.88.164
```

Determining the Number of file system Threads

About this task

You can run the [mrconfig info threads](#) on page 3317 command to view file system threads from all the instances. The output is tagged to identify the instance.

Converting a Cluster from Root to Non-Root User from the Command-Line

Provides a synopsis of changing the running user from root to a non-root user on a cluster.

You can change a Data Fabric cluster that runs as root to a non-root user. In addition to converting the Data Fabric user to a non-root user, you can also disable superuser privileges to the cluster for the root user for additional security.

WARNING: You must perform these steps on all nodes on a stable cluster. Do not perform this procedure concurrently while upgrading packages.

Converting a Data Fabric Cluster from Root to Non-Root User from the Command-Line

Lists the process to change the running user from root to a non-root user on a cluster.

Procedure

1. Create a user with the same UID/GID across the cluster. Assign that user to the MAPR_USER environment variable.

2. On each node:

- a) Stop the warden and the ZooKeeper (if present).

```
service mapr-warden stop
service mapr-zookeeper stop
```

- b) Run the config-mapr-user.sh script to configure the cluster to start as the non-root user.

```
/opt/mapr/server/config-mapr-user.sh -u <MapR user> [-g <MapR group>]
```

- c) Start the ZooKeeper (if present) and the warden.

```
service mapr-zookeeper start
service mapr-warden start
```

3. After the previous step is complete on all nodes in the cluster, run the upgrade2mapruser.sh script on all nodes.

```
/opt/mapr/server/upgrade2mapruser.sh
```

This command may take several minutes to return. The script waits ten minutes for the process to complete across the entire cluster. If the cluster-wide operation takes longer than ten minutes, the script fails. Re-run the script on all nodes where the script failed.

WARNING: The MAPR_UID_MISMATCH alarm may be raised during this process. The alarm will be cleared when this process is complete on all nodes.

Disabling Superuser Access for the Root User from the Command-Line

Describes how to disable superuser access for the root user.

About this task

NOTE: Enabling the cldb.squash.root **OR** cldb.reject.root configuration values can cause instability with ecosystem open source components if they are running as root. [On Data Fabric clusters, services are running as the admin cluster user, which is mapr (by default).] Root squash applies only to files, not tables or streams. Ensure that root is not running any services before performing this procedure.

IMPORTANT: You can enable either of the following parameters, but NOT both.

Procedure

1. To disable root user (UID 0) access to the Data Fabric filesystem on a cluster that is running as a non-root user, use either of the following commands:
 - The squash root configuration value treats all requests from UID 0 as coming from UID -2 (nobody):

```
/opt/mapr/bin/maprcli config save -values {"cldb.squash.root":"1"}
```

- The *reject root* configuration value automatically fails all filesystem requests from UID 0.

```
/opt/mapr/bin/maprcli config save -values {"cldb.reject.root":"1"}
```

2. You can verify that these commands worked, as shown in the following example.

```
/opt/mapr/bin/maprcli config load -keys cldb.squash.root,cldb.reject.root
cldb.reject.root cldb.squash.root
0 1
```

Starting Up a Cluster

Lists the steps to start a cluster that was previously shut down.

Procedure

1. If the cluster nodes are not running, start them.
2. Change to the root user (or use sudo for the following commands).
3. Start ZooKeeper on the nodes where it is installed:

```
service mapr-zookeeper start
```

4. On all nodes, start Warden:

```
service mapr-warden start
```

5. Over a period of time (depending on the cluster size and other factors), the cluster comes up automatically. After the CLDB restarts, there is a 15-minute delay before replication resumes. This delay allows all nodes to register and begin heartbeat processing. You can configure this delay by using the [config save](#) on [page 2394](#) command to set the `cldb.replication.manager.start.mins` parameter.

Shutting Down a Cluster

Lists the considerations to note and the procedure to shutdown a cluster.

Prerequisites

Verify that MapReduce processes are not active, and that no data is being loaded to the cluster or being persisted within the cluster.

About this task

When you shut down a cluster, follow this sequence to preserve your data and replication:

1. Verify that recent data has finished processing.
2. Shut down any NFS servers.
3. Shut down any ecosystem components that are running.
4. Shut down ResourceManager and NodeManager services if you are using YARN
5. Shut down Warden on all nodes that are not running CLDB.
6. Shut down Warden on the CLDB nodes.

7. Shut down ZooKeeper on the ZooKeeper nodes.

Complete the following steps to shut down the cluster:

Procedure

1. Change to the root user (or use sudo for the following commands).
2. Before shutting down the cluster, you will need a list of NFS nodes, CLDB nodes, and all remaining nodes. Once the CLDB is shut down, you cannot retrieve a list of nodes; it is important to obtain this information at the beginning of the process. Use the [node list](#) on page 2570 command as follows:
 - Determine which nodes are running the NFS gateway. Example:

```
/opt/mapr/bin/maprcli node list -filter "[rp==/*]and[svc==nfs]" -columns id,h,hn,svc,rp
id
service
hostname          health ip
6475182753920016590
fileserver,nodemanager,nfs,hoststats
node-252.cluster.us 0      10.10.50.252
8077173244974255917
nodemanager,cldb,fileserver,nfs,hoststats
node-253.cluster.us 0      10.10.50.253
5323478955232132984
webserver,cldb,fileserver,nfs,hoststats,resource manager
node-254.cluster.us 0      10.10.50.254
```

- Determine which nodes are running the CLDB. Example:

```
/opt/mapr/bin/maprcli node list -filter "[rp==/*]and[svc==cldb]" -columns id,h,hn,svc,rp
```

- List all non-CLDB nodes. Example:

```
/opt/mapr/bin/maprcli node list -filter "[rp==/*]and[svc!=cldb]" -columns id,h,hn,svc,rp
```

3. Shut down all NFS instances. Example:

```
/opt/mapr/bin/maprcli node services -nfs stop -filter [svc=="nfs"]
```

4. If your cluster is running any ecosystem components, shut down those components on all nodes.
5. Shut down all ResourceManager and NodeManager services on all nodes. To shut down ResourceManager and NodeManager services specify the [maprcli node services](#) command with the name parameter and either the filter or the node parameter. Example:

```
maprcli node services -name resource manager -filter <filter> -action stop
maprcli node services -name nodemanager -nodes <node> -action stop
```

6. SSH into each node that is not running CLDB and stop Warden with the command:

```
service mapr-warden stop
```

- SSH into each CLDB node and stop Warden with the command:

```
service mapr-warden stop
```

- SSH into each Zookeeper node and stop Zookeeper with the command:

```
service mapr-zookeeper stop
```

- (Optional) Shut down the nodes using the Linux `halt` command.

Allocating Cluster Resource from the Command-Line

Provides a general overview on allocating cluster resources for a Data Fabric Hadoop cluster.

In a Data Fabric Hadoop cluster, the Warden sets the default resource allocation for the operating system, file system, Data Fabric Hadoop services, and YARN applications. Warden allocates resources to Data Fabric Hadoop services and applications based on the roles installed on a node. For example, Warden allocates resources for YARN applications on nodes with NodeManager role installed.

In general, you should not need to override the values set in the default configuration files and by Warden. However, you can provide updated values by adding or updating parameters in the Hadoop site configuration files or Warden files. To override parameter values for a single job, the option can be overridden in the command line when submitting a YARN application to the cluster.

To determine the current value of a hadoop parameter, run `hadoop conf | grep <ParameterName>`. In the following example, the `hadoop conf` command was used to get the value of `mapreduce.map.memory.mb`:

```
hadoop conf | grep mapreduce.map.memory.mb
<property><name>mapreduce.map.memory.mb</name><value>1024</value><source>mapred-site.xml</source></property>
```

Alternatively, run `hadoop conf` without the `grep` command to get a full list of the current parameter values. To determine the current value of a Warden parameter, open the Warden files located in the following directories: `/opt/mapr/conf/conf.d` and `/opt/mapr/conf`.

NOTE: In some cases, the current value of the parameter can only be seen in the Control System or in ResourceManager.

Refer to [Allocating Memory for Nodes](#) on page 1387 to allocate memory and resources in a Data Fabric cluster.

Administering Nodes

Provides a synopsis of managing nodes in a cluster.

This section provides information about managing nodes in a Data Fabric cluster. Topics include how to add nodes to the cluster and/or remove nodes from the cluster, manage the services installed on the nodes, and manage disks. You can manage [nodes](#), [disks](#), and [services](#) in the Data Fabric cluster using the Control System and the CLI.

Managing Nodes

Describes the Nodes page on the Control System.

The **Nodes** page contains panes that display:

- [Node Health](#) — the health of the nodes organized by topology (by default) or service.
- [Current Resource Utilization](#) — the nodes that utilize the most (in percentage) CPU and memory.

- [Active Node Alarms](#) — the list of active node alarms on the cluster.
- [List of nodes](#) — the list of nodes on the cluster.

NOTE: The **Nodes** page is not available in the Kubernetes version of the Control System.

You can perform the following procedures to manage and monitor nodes using the Control System and the CLI:

Viewing the list of Nodes

Explains how to view the list of Nodes using either the Control System or the CLI.

Viewing the list of Nodes on the Control System

About this task

Procedure

- Log in to the Control System and click **Nodes**.

NOTE: The **Nodes** page is not available in the Kubernetes version of the Control System.

The page contains the following panes:

Node Health	Displays each node's health.
Active Alarms	Displays active alerts for nodes in the cluster.
Current Resource Utilization	Plots the current CPU and memory utilization for each node as a graph. This helps visualize the nodes that utilize the most CPU and memory.
Nodes	Displays all the nodes in the cluster.

For each node in the cluster, the **Nodes** pane displays the following:

Column Name	Column Description
Health	The health of the node. Value can be: <ul style="list-style-type: none"> ■ — Healthy ■ — Degraded ■ — Critical ■ — Maintenance
Hostname	The hostname of the node.
Physical IPs	The physical IP address or addresses associated with the node.
Last FS Heartbeat	The time since the node's last heartbeat to the CLDB.
Memory Utilized	The amount of memory used by the node.
Memory Total	The total amount of memory on the node.
CPU Utilized	The CPU usage metric for the node.
Disk Utilized	The amount of disk space utilized on the node.
Total Disk Space	The total amount of disk space on the node.
Physical Topology	The rack path to the node.

Column Name	Column Description
Running Services	The number of services running on the node.

Selecting the checkbox beside a node makes the following buttons available:

- [Change Topology](#)
- [Remove Nodes](#)
- [Manage Services](#)

Retrieving the list of Nodes Using the CLI or REST API

About this task

The basic command to view all the nodes on a cluster is:

```
maprcli node list -cluster <cluster>
```

For complete reference information, see [node list](#) on page 2570.

Customizing the List of Columns/Fields

Explains how to customize the columns that are displayed in the Control System, and the fields that are returned in the CLI.

Customizing the Columns in the Control System

Procedure

1. Log in to the Control System and go to:
 - **Data > Volumes** page to customize columns displayed in the **Volumes** pane.

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

 - **Nodes** page to customize columns displayed in the **Nodes** pane.

NOTE: The **Nodes** page is not available on the Kubernetes version of the Control Panel.
2. Click the **Customize Columns** icon ().
In the **Customize Columns** dialog, the:
 - **Available** list displays the columns that are available for display.
 - **Selected** list displays the columns currently displayed in the pane.
3. Select the columns from the:
 - a) Available list of columns and click  to move selection to **Selected** columns (for display).
 - b) Selected list of columns and click  to remove selected columns from displaying.
4. (Optional) Click  and/or down  arrows to sort the order of columns.
5. Click **Save Changes** for the customization to take effect.

TIP: To reset the display to its default columns, click **Reset to default columns**.

*Customizing the Fields Using the CLI or REST API***About this task**

Use the `-column` parameter with the `maprc li` command to view specific fields in the list. For example:

- To view the health of the nodes and services installed on the nodes being retrieved, run the following command:

```
maprc li node list -columns service,health
```

For complete reference information, see the [node list](#) on page 2570 command.

- To view the volume name for the list of volumes being retrieved, run the following command:

```
maprc li volume list -columns volumename
```

For complete reference information, see [volume list](#) on page 2989 command.

Reverting to Default List of Columns

Describes how to revert to the default list of columns on the Control System

Procedure

1. Log in to the Control System and click:

- **Data > Volumes** to revert to the default list of columns in the **Volumes** pane.

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

- **Nodes** to revert to the default list of columns in the **Nodes** pane.

NOTE: The **Nodes** page is not available in the Kubernetes version of the Control System.

2. Click the **Customize Columns** icon (🔧).

3. Click **Reset to default columns**,

4. Click **Save Changes**.

The pane displays the default list of columns.

Filtering the List of Nodes

Describes how to setup search expressions and filter nodes based on specific criteria.

About this task

The filter lets you build search expressions to provide sophisticated filtering capabilities for locating specific data on views that display a large number of nodes. Expressions are implicitly connected by the AND operator.

*Filtering the Node List in the Control System***Procedure**

1. Log in to the Control System and click **Nodes** to filter the list of nodes in the **Nodes** pane.

NOTE: The **Nodes** menu is not available on the Kubernetes version of the Control System.

2. Click  and select one of the following from the **Add Filter** drop down menu.

- Health — to filter the list by node health
- Hostname — to filter the list by hostname of node
- Physical IP — to filter the list by IP address of node
- Last FS Heartbeat — to filter the list by number of heartbeats sent to FS
- CPU Utilized — to filter the list by number of cores utilized
- Physical Topology — to filter the list by rack path
- Running Services — to filter the list by installed services

3. Specify the value in the drop-down field for the selected filter (to filter the list of nodes by) and click **Filter**.

As you make selections and specify the filtering criteria, the pane displays only the nodes that match the specified filtering criteria.

4. Click:

- **Add Filter** to add another filtering criteria.
-  to remove a filtering criteria.
-  to clear all filter settings.

Filtering the List Using the CLI

About this task

Use the [node list](#) on page 2570 command with the `-filter` option, to specify large numbers of nodes by matching specified values in specified fields rather than by typing the name of each node explicitly. For example, you can retrieve all nodes on a specific subnet as follows:

```
maprcli node list -filter [ip==20.30.40.*]
```

For more information, see [Filters](#) on page 2270.

Monitoring Nodes

Explains how to monitor nodes using either the Control System or the CLI.

About this task

You can check the health of the nodes on the cluster in the Control System, organized by service or by topology, or by using the CLI.

NOTE: To visualize the graphs and charts, you must install the metrics collection infrastructure during installation. If the metrics collection infrastructure is not installed, perform an [Incremental Install](#) to install the metrics collection infrastructure.

NOTE: The **Nodes** page is not available on the Kubernetes version of the Control System.

Monitoring Node Health Using the Control System

About this task

To monitor the health of nodes:

Procedure

1. Log in to the Control System and click:

- **Overview** to view the health of the nodes in the **Node Health** pane.
- **Nodes** to view the health of the nodes in the **Node Health** pane.

2. Select one of the following from the drop-down menu in the **Node Health** pane.

- **By Service** to organize the display of nodes by services.

This is the default view in the **Overview** page. This view contains the list of services and the nodes on which the service is running (■) and is down (■).

NOTE: The color of the node (which reflects the status of the service) is ■ even when a service is stopped (not running) on the node.

- **By Topology** to view the display of nodes by topology.

This is the default view in the **Nodes** page. This view contains the list of topologies and the health of the nodes (as shown in the following table) in the topology.

Node Color	Description
■	Indicates the node is healthy.
■	Indicates the node is degraded and/or may need attention. A node is considered to be in degraded state if: <ul style="list-style-type: none"> • There is no heartbeat from the HPE Data Fabric filesystem/NFS node for over 60 seconds. • One or more services are down on the node. • One or more alarms are raised on the node.
■	Indicates the node is in maintenance mode.
■	Indicates critical issue(s) on the node. A node is considered to be in critical state if: <ul style="list-style-type: none"> • There is no heartbeat from the node for more than 5 minutes. • All HPE Data Fabric files system disks on the node are dead or are offline. • All containers on the node are being re-replicated because either the node was removed, unregistered, or there was no heartbeat from the node for more than 1 hour. • File server is dead/inactive because there is no heartbeat for a long time. • NFS server on node is dead. • HPE Data Fabric install directory is full. • Node reported high HPE Data Fabric filesystem memory usage.

Monitoring Node Resource Utilization from the Control System

Procedure

- Log in to the Control System and click **Nodes** to view the nodes that consumed the most CPU and memory (in percentage) in the **Current Resource Utilization** pane. The shade of the bubble indicates node resource utilization with the darker shade indicating the nodes that are nearing disk capacity.

Monitoring Active Node Alarms from the Control System

About this task

See [Viewing Active Node Alarms](#) on page 1956 for more information.

Monitoring Node Health Using the CLI or REST API

About this task

You can check general health of the nodes with the following command:

```
maprcli node heatmap -cluster <cluster>
```

This command displays a heatmap for the nodes on the specified cluster; a subset of the output can also be visualized on the Control System. For complete reference information, see [node heatmap](#) on page 2568.

Gathering Node Metrics

Explains how to gather node metrics using the CLI.

About this task

You can gather metrics such as IO statistics, network throughput, CPU performance, memory consumption, swap space usage, disk usage, disk latency, and MFS throughput for each node, using the [mr diagnostics](#) on page 3341 utility.

Viewing Node Details

Describes how to view node details using either the Control System or the CLI.

Viewing Node Details Using the Control System

Procedure

1. Log in to the Control System and click **Nodes**.

NOTE: The **Nodes** page is not available in the Kubernetes version of the Control System.

2. Click the hostname of the node.
The information page for the node displays.

- [Summary tab](#) (default view)
- [Metrics tab](#)

You can:

- [Change the topology of the node](#)
- [Remove the node](#)

Viewing Node Details Using the CLI or REST API

About this task

The basic command to retrieve information on a node is:

```
maprcli node metrics -nodes <hostname> -columns <column names>
```

For complete reference information, see [node metrics](#) on page 2591.

Viewing Node Summary

View a summary of the alarms, services, and disks on a node using either the Control System or the CLI.

Viewing Node Summary Using the Control System

Procedure

- Log in to the Control System and go to the [node information page](#).
The page with information on the node displays and the **Summary** tab displays by default. The **Summary** tab contains panes for node-specific:
 - Alarms** — displays active and recent alarms on the node. See [Viewing Active Node Alarms](#) on page 1956 for more information.
 - Services** — displays services running on the node. See [Viewing the Services Running on a Node Using the Control System](#) on page 1398 for more information.
 - Disks** — displays information on the disks on the node. See [Viewing the List of Disks](#) on page 1406 for more information.

Viewing Node Summary Using the CLI

About this task

The basic command to retrieve a summary of the disks on a node is:

```
maprcli node metrics -nodes <hostname> -columns DISKS
```

For complete reference information, see [node metrics](#) on page 2591.

Viewing Node Metrics

Explains how to view node metrics using the Control System.

About this task

NOTE: The metrics collection infrastructure must be installed during installation to visualize the metrics in the various panes. If the metrics collection infrastructure is not installed, perform an [Incremental Install](#) to visualize the metrics that are described in the following section.

Monitoring Node Metrics Using the Control System

Procedure

- Log in to the Control System and go to the **Metrics** tab in the [node information page](#).
By default, the page displays charts that show metrics for the last 24 hours. You can select a preset or specify a custom time range.

Time Range From: 2018-07-22 14:40 To: 2018-07-23 14:40 Apply	Last 2 days Last 7 Days Last 30 Days	Yesterday Day before yesterday This day last week Previous week Previous month	Today Today so far This week This week so far This month This month so far	Last 5 minutes Last 15 Minutes Last 30 minutes Last 1 Hour Last 3 hours Last 6 hours Last 12 Hours Last 24 Hours
--	--	--	---	---

You can also zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Zoom Out** to expand time window or click:

-  to shift time window forwards.
-  to shift time window backwards.

Click  associated with the chart to view information about the graph. Click  to display the **Customize Active Charts** window. You can select charts to display and remove from the **Available** and **Selected** lists in the **Customize Active Charts** window. You can view up to 6 charts at a time in the page.

Use the following table when selecting the charts to view in the page. In the following table, the Charts column lists the charts that are available and the Metric column describes that type of metric that can be visualized in the chart:

Metric	Charts
CPU Usage	<ul style="list-style-type: none"> • Node Active CPU Usage • Node CPU Usage** • Node CPU Usage IDLE • Node CPU Usage NICE • Node CPU Usage SYSTEM • Node CPU Usage USER • Node CPU Usage WAIT • MFS CPU Usage • Allocated vs Available CPU Cores • MapR Process CPU Usage • MAST Gateway CPU Usage • DB Gateway CPU Usage • Data Access Gateway CPU Usage
Memory Usage	<ul style="list-style-type: none"> • Node Free Memory • Node Utilized Memory*** • Node Memory Free vs Used* • MFS Process Memory Usage • Data Fabric Process Memory Usage
SWAP Space	<ul style="list-style-type: none"> • Node Swap Free • Node Swap Used • Node Swap Space Available vs Used* • Node Swap IO

Metric	Charts
Node IOs	<ul style="list-style-type: none"> Node Network IO* Node Network Interface Input Node Network Interface Output Node Network Interface Error Input Node Network Interface Error Output
System Disk Throughput	<ul style="list-style-type: none"> Disk Read Ops Disk Write Ops Disk Reads and Writes*
System Disk Latency	<ul style="list-style-type: none"> Disk Avg Read Latency Disk Avg Write Latency Disk Read and Write Times
MFS Throughput	<ul style="list-style-type: none"> MFS Read Throughput MFS Write Throughput MFS Read and Write Throughput MFS System Disk Activity in Bytes*

* This metric is displayed in the default chart view for a node.

** This metric is displayed in the default chart view for a node and in the default list view for a table.

*** This metric is displayed in the default list view for a table.

For information on viewing metrics for:

- All table activities on a node, see [Viewing Per Node Metrics for Table Activities](#) on page 1935.
- All stream activities on a node, see [Monitoring Streams Operations Using the Control System](#) on page 1952.

Setting Up Node Topology

Define node topologies for every node in the cluster.

Define your cluster's topology by specifying a topology for each node in the cluster. You can use topology to group nodes by rack or switch, depending on how the physical cluster is arranged and how you want Data Fabric to place replicated data.

Topology paths can be as simple or complex as needed to correspond to your cluster layout. In a simple cluster, each topology path might consist of the rack only (for example, /rack-1). In a deployment consisting of multiple large datacenters, each topology path can be much longer (for example, /europe/uk/london/datacenter2/room4/row22/rack5/). Data Fabric uses topology paths to spread out replicated copies of data, placing each copy on a separate path. By setting each path to correspond to a physical rack, you can ensure that replicated data is distributed across racks to improve fault tolerance.

Changing the Topology of one or more Nodes

Describes how to move nodes from one topology to the other using either the Control System or the CLI.

*Changing the Topology of Multiple Nodes Using the Control System***About this task**

To change the rack or switch path for one or more nodes, under **Nodes**:

NOTE: The **Nodes** menu is not available on the Kubernetes version of the Control System.

Procedure

1. Select the nodes from the list of nodes in the **Nodes** pane and click **Change Topology**. The **Change Node Topology** dialog displays.
2. Choose one of the following:
 - **Select Existing Topology** to select a topology from the list of existing topologies.
 - **Create New Topology** to specify a new topology for the selected nodes.
3. Click **Change Topology** for the changes to take effect.

*Changing the Topology of a Node Using the Control System***About this task**

To change the rack or switch path for a node:

Procedure

1. Go to the [node information page](#) and click **Change Topology**. The **Change Node Topology** dialog displays.
2. Choose one of the following:
 - **Select Existing Topology** to select a topology from the list of existing topologies.
 - **Create New Topology** to specify a new topology for the node.
3. Click **Change Topology** for the changes to take effect.

*Changing the Topology Using the CLI or REST API***About this task**

The basic command to move nodes to a different topology is:

```
/opt/mapr/bin/maprccli node move -serverids <server IDs> -topology <topology>
```

For complete reference information, see [node move](#) on page 2596.

The move will fail if the server ID is negative. To fix this issue, perform one of the following:

- If you are moving only a single server ID that is negative, or a bunch of server IDs that are all negative, prefix 0 as an additional server ID. For example:

```
/opt/mapr/bin/maprccli node move -serverids  
0, -6151492882499457449, -2668056288676628812 -topology /data/mytopo -json
```

- If you are moving a bunch of server IDs with a mix of positive and negative server IDs, place a positive ID as the first ID. For example:

```
/opt/mapr/bin/maprccli node move -serverids
1507661865183706279, -6151492882499457449, -2668056288676628812 -topology /
data/mytopo -json
```

Setting Node Topology with a Script

Provides an overview of how to script setting up node topology.

For large clusters, you can specify complex topologies in a text file or by using a script. Each line in the text file or script output specifies a single node and the full topology path for that node in the following format:

```
<ip or hostname> <topology>
```

The text file or script must be specified and available on the local filesystem on all CLDB nodes:

- To set topology with a text file, set `net.topology.table.file.name` in `/opt/mapr/conf/cldb.conf` to the text file name
- To set topology with a script, set `net.topology.script.file.name` in `/opt/mapr/conf/cldb.conf` to the script file name

If you specify a script and a text file, the Data Fabric system uses the topology specified by the script.

Adding Nodes to a Cluster

Describes how to add nodes to a cluster.

About this task

You can add nodes to a cluster using the web-based Installer (version 1.6 or later), the Installer Stanzas, or manually. To add nodes to your cluster using the Installer or Installer Stanzas, see [Extending a Cluster by Adding Nodes](#) on page 7556. Complete the following steps to add nodes manually to a cluster:

Procedure

1. Prepare all nodes.

If you do not use the Domain Name System (DNS), ping the new node from an existing node and vice versa. Use the host name instead of an IP address. If you do not get a response, and if you rule out a network problem, a possible fix is to edit the `/etc/hosts` files of all nodes in the cluster. All nodes need to be listed in all `/etc/hosts` files.

2. Plan which packages to install based on services you want to run on the new nodes.

See [Select Services](#) on page 77 and [Data Fabric Repositories and Packages](#) on page 152 for more information.

3. Install HPE Data Fabric Software.

- On all new nodes, add the HPE Data Fabric Repository.
- On each new node, install the planned packages.

See [Step 3: Prepare Packages and Repositories](#) on page 233 and [Step 4: Install Cluster Service Packages](#) on page 244 for more information.

4. Configure all new nodes by running `configure.sh`.

If you added a ZooKeeper role to a node, run the following command on all nodes with the new ZooKeeper list: `configure.sh -no-autostart`. See [configure.sh](#) on page 3186 for more information.

5. On all new nodes, format disks for use by HPE Data Fabric if you plan to re-use a node from another cluster.

Format the disks from a re-used node to remove data from the old cluster.

NOTE: All the disks (for use by HPE Data Fabric) on a node must be of the same type. That is, all the disks on a node must either be rotational or SSDs; node with disks of both types is not supported.

See [Formatting Disks on a Node From the Command-line](#) on page 1412 for more information.

6. If you manually modified configuration files on the existing nodes and those changes apply to the new nodes, copy only those changes to the respective files on the new nodes.

7. Perform the following steps if you added the node(s) to any secure cluster that is configured for cross-cluster operations.

a) Copy the `/opt/mapr/conf/mapr-clusters.conf` file and `/opt/mapr/conf/ssl_truststore` file from another node to the new node(s).

b) Copy the `/opt/mapr/conf/maprserverticket` file from:

- A CLDB node if the new node is a CLDB node.
- A non-CLDB node if the new node is not a CLDB node.

The `/opt/mapr/conf/maprserverticket` file contains additional entry for cross-cluster tickets. See [Configuring Secure Clusters for Cross-Cluster NFS Access](#) on page 2231 for more information.

8. Start ZooKeeper on all new nodes that have ZooKeeper installed:

```
service mapr-zookeeper start
```

9. Start Warden on all new nodes:

```
service mapr-warden start
```

10. Restart services that you reconfigured.

Running `configure.sh` alone does not reconfigure services, such as ZooKeeper. Reconfigured services also require a restart. For example, restart ZooKeeper on each node, one at a time after running `configure.sh`. Restart the lead ZooKeeper last. Restarting ZooKeeper adds the new nodes into the existing ZooKeeper quorum. Services that need to connect to CLDB do not always discover a newly added CLDB node without restarting warden.

11. Set up node topology for the new nodes.

12. On any new nodes running NFS, set up NFS for HA.

Isolating CLDB Nodes

Lists the pros of creating CLDB-only nodes.

In a large cluster (100 nodes or more) create CLDB-only nodes to ensure high performance. This configuration also provides additional control over the placement of the CLDB data, for load balancing, fault tolerance, or high availability (HA). Setting up CLDB-only nodes involves restricting the CLDB volume to its own topology and making sure that all other volumes are on a separate topology. As both the

CLDB-only path and the non-CLDB path are children of the root topology path, new non-CLDB volumes are not guaranteed to keep off the CLDB-only nodes. To avoid this problem, set a default volume topology. See [Setting Default Volume Topology Using the CLI](#) on page 1494.

Setting Up a CLDB-Only Node

Describes how to setup a node for CLDB alone.

Procedure

1. SET UP the node as usual:
 - a) **PREPARE** the node, making sure it meets the requirements.
 - b) **ADD** the Data Fabric repository.
2. **INSTALL** the following packages to the node.
 - `mapr-cldb`
 - `mapr-webserver`
 - `mapr-core`
 - `mapr-fileserver`

Setting Up Volume Topology to Restrict the CLDB Volume to Specific Nodes

Explains how to permit access to CLDB volumes only from specific nodes.

Procedure

1. Move all CLDB nodes to a CLDB-only topology (e. g. `/cldbonly`) using the Control System or the following command:

```
maprcli node move -serverids <CLDB nodes> -topology /cldbonly
```

2. Restrict the CLDB volume to the CLDB-only topology using the Control System or the following command:

```
maprcli volume move -name mapr.cldb.internal -topology /cldbonly
```

Moving Volumes to a Separate Topology from the CLDB-Only Nodes

Explains how to move non-CLDB volumes to a separate topology.

Procedure

1. Move all non-CLDB nodes to a non-CLDB topology (e. g. `/defaultRack`) using the Control System or the following command: `maprcli node move -serverids <all non-CLDB nodes> -topology /defaultRack`
2. Restrict all existing volumes to the topology `/defaultRack` using the Control System or the following command: `maprcli volume move -name <volume> -topology /defaultRack`
All volumes except `mapr.cluster.root` are re-replicated to the changed topology automatically.

WARNING: To prevent subsequently created volumes from encroaching on the CLDB-only nodes, set a default topology that excludes the CLDB-only topology.

Isolating ZooKeeper Nodes

Provides an overview on how to install a ZooKeeper-only node.

For large clusters (100 nodes or more), isolate the ZooKeeper on nodes that do not perform any other function. Isolating the ZooKeeper node enables the node to perform its functions without competing for resources with other processes. Installing a ZooKeeper-only node is similar to any typical node installation, but with a specific subset of packages.

WARNING: Do not install the FileServer package on an isolated ZooKeeper node in order to prevent Data Fabric from using this node for data storage.

Setting Up a ZooKeeper-Only Node

Explains how to install a ZooKeeper-only node.

Procedure

1. SET UP the node as usual:
 - a) **PREPARE** the node, making sure it meets the requirements.
 - b) **ADD** the HPE Data Fabric Repository.
2. **INSTALL** the following packages to the node.
 - `mapr-zookeeper`
 - `mapr-zk-internal`
 - `mapr-core`

Configuration Example

This example assumes you are adding a new node to a cluster that is running the CLDB and ZooKeeper on three other nodes: `node_a`, `node_b`, and `node_c`. To configure a new `node_d`, which is not a CLDB or ZooKeeper node, run the following command:

```
$ /opt/mapr/server/configure.sh -N my.cluster.com -C
node_a,node_b,node_c -Z node_a,node_b,node_c
```

To configure a ZooKeeper node, use the `-no-autostart` option and the `-Z` option followed by the list of ZooKeeper nodes.

Removing Nodes from a Cluster

Provides an overview of how to remove nodes from a cluster.

You can remove a node using the `node remove` command, or using the Control System. Removing a node detaches the node from the cluster, but does not remove the HPE Data Fabric software from the cluster.

The following sections provide information about removing nodes from a cluster:

Removing One or More Nodes

Describes how to decommission a node from service.

Prerequisites

Perform the following prerequisite steps before removing a node using the Control System or CLI or REST API:

1. Drain the node of data by **moving** the node to the `/decommissioned` physical topology. All the data on a node in the `/decommissioned` topology is migrated to other volumes and nodes in the appropriate topologies.

2. Run the following command to check if a given volume is present on the node:

```
maprcli dump volumenodes -volumename <volume> -json | grep IP:Port
```

As an example, consider the volume `rocky` that is present on a node with IP `10.163.167.212`. To check whether this volume exists on this node, run the command:

```
maprcli dump volumenodes -volumename rocky -json
{
  "timestamp":1606879372378,
  "timeofday":"2020-12-01 07:22:52.378 GMT-0800 PM",
  "status":"OK",
  "total":1,
  "data":[
    {
      "Servers":{
        "IP:Port":"10.163.167.212:5660-192.168.122.1:5660--3-VALID"
      }
    }
  ]
}
```

The output shows that the volume `rocky` exists on node `10.163.167.212` that is accessible on port `5660`.

To return just the IP and the Port alone, pipe the output through the `grep` command as follows:

```
maprcli dump volumenodes -volumename test -json | grep IP:Port
"IP:Port":"10.163.167.212:5660-192.168.122.1:5660--3-VALID"
```

Run this command for each non-local volume in your cluster to verify that the node being removed is not storing any volume data.

3. Install CLDB or ZooKeeper on another node (only) if the node you are removing is a CLDB or ZooKeeper node and run `configure.sh` with `-C` and `-Z` options.

This is to ensure that ZooKeeper quorum is maintained and that an optimal number of CLDB is available for high availability.

About this task

You can remove one or more nodes using the Control System and the CLI.

Removing Multiple Nodes Using the Control System

About this task

To remove one or more nodes:

Procedure

1. Log in to the Control System and click **Nodes**.

NOTE: The **Nodes** menu is not available on the Kubernetes version of the Control System.

2. Select the nodes from the list of nodes in the **Nodes** pane and click **Remove Node(s)**.
The **Remove Node(s)** dialog displays.

3. Verify the list of nodes to remove and click **Remove Nodes**.

Removing a Node Using the Control System

About this task

To remove a node:

Procedure

1. Go to the [Viewing Node Details](#) on page 1369 page and click **Remove Node**.
The **Remove Node(s)** confirmation dialog displays.
2. Click **Remove Node**.

Removing one or more Nodes Using the CLI or REST API

About this task

Use the [node remove](#) on page 2597 command to remove one or more server nodes from the cluster. To run this command, you must have full control (fc) or administrator (a) permission. The syntax is:

```
maprcli node remove -nodes <node names> ]
```

If the following error is generated, you must wait for the state duration of the CLDB master node to reach 15 minutes or more. Otherwise, the node remove fails:

```
node remove failed for node <node_name>, Error: Resource temporarily
unavailable; CLDB just became master, node removed not allowed until
sometime
```

To check the state duration value, use this command:

```
maprcli dump cldbstate -json
```

After you issue the [node remove](#) on page 2597 command, wait several minutes to ensure that the nodes have been completely removed.

TIP: To ensure that a node that is removed does not rejoin the cluster on reboot, either remove all Data Fabric packages from the node, or remove the cluster configuration that is present in the `/opt/mapr/conf/mapr-clusters.conf` file on the node.

Related concepts

[Migrating a Volume off a Node Using the CLI](#) on page 1491

Decommissioning a Node and Uninstalling Data Fabric Software from the Command Line

About this task

Use the following procedure to remove a node and uninstall Data Fabric software. This procedure detaches the node from the cluster and removes the Data Fabric packages, log files, and configuration files, but does not format the disks.

NOTE: Before decommissioning a node, make sure any data on the node is replicated and any needed services are running elsewhere. If the node you are decommissioning runs a critical service, such as CLDB or ZooKeeper, verify that enough instances of that service are running on other nodes in the cluster. See [Planning the Cluster](#) for recommendations about service assignment to nodes.

Complete the following steps to permanently decommission a node:

Procedure

1. Drain the node of data by moving the node to the /decommissioned physical topology. All data on a node in the /decommissioned topology is migrated to volumes and nodes in the data topology.
2. Run the following command to check if a given volume is present on the node:

```
maprcli dump volumenodes -volumename <volume> -json | grep <ip:port>
```

NOTE: Run this command for each non-local volume in your cluster to verify that the node being decommissioned is not storing any volume data.

3. Change to the root user (or use sudo for the following commands).
4. Stop Warden on the node by running the following command:

```
service mapr-warden stop
```

5. If ZooKeeper is installed on the node, stop it: `service mapr-zookeeper stop`
6. Determine which Data Fabric packages are installed on the node:
 - `dpkg --get-selections | grep mapr` (Ubuntu)
 - `rpm -qa | grep mapr` (Red Hat or CentOS)
7. Remove the packages by issuing the appropriate command for the operating system, followed by the list of services. Examples:
 - `apt-get purge mapr-core mapr-cldb mapr-fileserver` (Ubuntu)
 - `yum erase mapr-core mapr-cldb mapr-fileserver` (Red Hat or CentOS)
8. Remove the /opt/mapr directory to remove any instances of hostid, hostname, zkdata, and zookeeper left behind by the package manager.
9. Remove the /mapr directory to delete any NFS/POSIX client mount points.
10. Remove any Data Fabric cores in the /opt/cores directory.
11. If the node you have decommissioned is a CLDB node or a ZooKeeper node, then run `configure.sh` on all other nodes in the cluster. See [Configuring the Node](#).
12. Remove the node by running the following command:

```
maprcli node remove -nodes <node-name>
```

Reconfiguring a Node from the Command-Line

Provides an overview of the procedure to reconfigure a node using the CLI.

This procedure is designed to make changes to existing HPE Data Fabric software on a machine that has already been set up as a HPE Data Fabric cluster node. If you need to install software for the first time on a machine to create a new node, see [Adding Nodes to a Cluster](#).

Complete the following steps to reconfigure a node:

1. Stopping the Node

Describes how to stop a node.

Procedure

1. Change to the root user (or use sudo for the following commands).
2. Stop Warden: `service mapr-warden stop`
3. Stop ZooKeeper, if installed on the node: `service mapr-zookeeper stop`

2. Formatting the Disks (Optional)

Provides an overview of how to format the disks.

If you are re-using a node that was used previously in another cluster, be sure to format the disks by using the [disksetup](#) script to remove any traces of data from the old cluster. Refer to the previous section, [Formatting Disks on a Node](#), for instructions.

3. Installing or Removing Software or Hardware

Lists the considerations to install or remove software or hardware.

When the node is stopped, you can add, upgrade or remove software or hardware. At some point after adding or removing services, you should restart Warden, to re-optimize memory allocation among all the services on the node. It is not crucial to perform this step immediately; you can restart Warden any time when the cluster is not busy.

To add or remove individual HPE Data Fabric packages, use the standard package management commands for your Linux distribution:

- `apt-get` (Ubuntu)
- `yum` (Red Hat or CentOS)

For information about the packages to install, see [Planning the Cluster](#).

The following sections provide information about adding or removing services from a node after it has been deployed in a cluster:

Adding a Service to an Existing Node

Explains how to add a service to a node.

About this task

The process of adding a service to a node is similar to the initial installation process for nodes. For further detail see [Installing Data Fabric Software](#).

Procedure

1. Install the package(s) corresponding to the new role(s) using `apt-get` or `yum`.
2. Run `configure.sh` with a list of the CLDB nodes and ZooKeeper nodes in the cluster.
3. If you added the CLDB or ZooKeeper role, you must run `configure.sh` on all other nodes in the cluster.
4. If you added the fileservers role, run `disksetup` to format and prepare disks for use as storage.
5. Restart Warden.

```
service mapr-warden restart
```

Results

When Warden restarts, it picks up the new configuration and starts the new services, making them active in the cluster.

Removing a Service from an Existing Node

Explains how to remove a service from a node.

Procedure

1. Stop the service you want to remove by using the Control System or the `maprccli` command-line tool. The following example stops the Fileserver service:

```
maprccli node services -fileserver stop -nodes mapr-node1
```

2. Purge the service packages with the `apt-get`, `yum`, or `zypper` commands, as suitable for your operating system.
3. Run the `configure.sh` script with the `-R` option.
4. When you remove the CLDB or ZooKeeper role from a node, run `configure.sh -R` on all nodes in the cluster.

4. Configuring the Node

Provides an overview of the `configure.sh` script to use to configure a node.

The script `configure.sh` configures a node to be part of a HPE Data Fabric cluster, or modifies services running on an existing node in the cluster. The script creates (or updates) configuration files related to the cluster and the services running on the node.

Before you run `configure.sh`, make sure you have a list of the hostnames of the CLDB and ZooKeeper nodes. You can optionally specify the ports for the CLDB and ZooKeeper nodes as well. The default ports are:

Service	Default Port #
CLDB	7222
ZooKeeper	5181

The script `configure.sh` takes an optional cluster name and log file, and comma-separated lists of CLDB and ZooKeeper host names or IP addresses (and optionally ports), using the following syntax:

```
/opt/mapr/server/configure.sh -C <host>[:<port>][,<host>[:<port>]...] -Z
<host>[:<port>][,<host>[:<port>]...] [-L <logfile>][-N <cluster name>]
```

NOTE:

Each time you specify the `-Z <host>[:<port>]` option, you must use the *same order* for the ZooKeeper node list. If you change the order for any node, the ZooKeeper leader election process will fail.

Example:

```
/opt/mapr/server/configure.sh -C
r1n1.sj.us:7222,r3n1.sj.us:7222,r5n1.sj.us:7222 -Z
r1n1.sj.us:5181,r2n1.sj.us:5181,r3n1.sj.us:5181,r4n1.sj.us:5181,r5n1.sj.us:5
181 -N MyCluster
```

5. Starting the Node

Explains how to start a node.

Procedure

1. If ZooKeeper is installed on the node, start it: `service mapr-zookeeper start`
2. Start Warden: `service mapr-warden start`

Renaming a Node from the Command-Line

Provides distribution-specific instructions for renaming a node.

Procedure

ATTENTION: Ensure that the host name you set is resolvable. Add the host name to the `/etc/hosts` file. For example: `10.10.19.22 host.qa.net`. Data Fabric installation and commands fail if the host name is not resolvable.

To rename a node:

1. Stop Warden on the node. Example:

```
service mapr-warden stop
```

2. If the node is a ZooKeeper node, stop ZooKeeper on the node. Example:

```
service mapr-zookeeper stop
```

3. Rename the host:

- Red Hat 6.x and CentOS 6.x: To preserve the new host name after reboot, edit the `HOSTNAME` parameter in the `/etc/sysconfig/network` file and restart the `xinetd` service or reboot the node. To change the host name temporarily without a reboot, run:

```
hostname desired-host-name
```

- Red Hat 7.x and CentOS 7.x: Run the command:

```
hostnamectl set-hostname desired-host-name --static
```

Alternatively, enter the host name in the `/etc/hostname` file, and run:

```
hostname -F /etc/hostname
```

Both these methods preserve the host name across reboots.

- On Ubuntu, first install `dbus` if it is not installed.

```
apt-get install dbus
```

Next, run the command:

```
hostnamectl set-hostname desired-host-name --static
```

Alternatively, edit the host name in the `/etc/hostname` file, and run:

```
hostname -F /etc/hostname
```

Both these methods preserve the host name across reboots.

4. If the node is a ZooKeeper node or a CLDB node, run [configure.sh](#) on page 3186 with a list of CLDB and ZooKeeper nodes.
5. If the node is a ZooKeeper node, start ZooKeeper on the node. Run:

```
service mapr-zookeeper start
```

6. Start Warden on the node. Run:

```
service mapr-warden start
```

What to do next

After you rename a:

- CLDB or ZooKeeper node, run [configure.sh](#) on page 3186 on all the nodes with the new host name, to update the `mapr-clusters.conf` file with the new host name. Ensure that there are no duplicate entries in the file. Also, verify that the new host is accessible from all the nodes.
- Node, some local volumes (such as for audit, and metrics) may exist with both the old and new host names. If you want, you can remove the local volumes with the old host name, use the existing local volume path, or remount to the new path.

Changing the IP Address of a Node

Describes how to change the IP address of any node in the cluster using the CLI.

Changing the IP Address of a Data Node

About this task

Complete the following steps to change the IP address of a data node:

Procedure

1. Shut down Warden and ZooKeeper on the node to be changed.

```
service mapr-zookeeper stop
service mapr-warden stop
```

2. Change the IP address of the node.
3. Edit the `/etc/hosts` file on all nodes to reflect the IP address change, or ensure that the IP addresses are resolvable through a DNS search.
4. On the node where you changed the IP address, restart the network interface. The interface shuts down, so you lose the connection.
5. Log into the node using the new IP address.
6. Check the IP address.
For example, run `ifconfig`.
7. If the `MAPR_SUBNETS` environment variable is set, edit the value for the `MAPR_SUBNETS` environment variable in the `/opt/mapr/conf/env.sh` file and make sure that the new IP address is part of it.
See [Setting Environment Variables for NIC Segregation](#) on page 1422 for more information.
8. Restart Warden on the node(s) where the IP address has changed.

9. Check that all nodes appear in the output of the node list command.

```
/opt/mapr/bin/maprcli node list -columns ip
```

You might have to wait a few minutes until all nodes are registered before you get the output from this command.

Changing the IP Address of CLDB Node

About this task

Complete the following steps to change an IP address of a CLDB node:

Procedure

1. Shut down Warden and ZooKeeper on the node to be changed.

```
service mapr-zookeeper stop
service mapr-warden stop
```

2. Change the IP address of the node.
3. Edit the `/etc/hosts` file on all nodes to reflect the IP address change, or ensure that the IP addresses are resolvable through a DNS search.
4. On the node where you changed the IP address, restart the network interface. The interface shuts down, so you lose the connection.
5. Log into the node using the new IP address.
6. Check the IP address. For example, run `ifconfig`.
7. Run `configure.sh`.
Use the `-C` option to provide a list of CLDB nodes.

NOTE:

If the initial setting was based on the IP address, run `configure.sh` on all nodes in the cluster.

If the initial setting was based on the hostname, there is no need to run `configure.sh` on any nodes when you change the IP address.

8. Perform a rolling restart of Warden on all the nodes.
9. Check that all nodes appear in the output of the node list command. You might have to wait a few minutes until all nodes are registered before you get output from this command.

```
/opt/mapr/bin/maprcli node list -columns ip
```

Changing the IP Address of ZooKeeper Node

About this task

Complete the following steps to change an IP address of a ZooKeeper node:

Procedure

1. Shut down Warden and ZooKeeper on the node to be changed.

```
service mapr-zookeeper stop
service mapr-warden stop
```

2. Change the IP address of the node.
3. Edit the `/etc/hosts` file on all nodes to reflect the IP address change, or ensure that the IP addresses are resolvable through a DNS search.
4. On the node where you changed the IP address, restart the network interface. The interface shuts down, so you lose the connection.
5. Log into the node using the new IP address.
6. Check the IP address.
For example, run `ifconfig`.
7. Run `configure.sh`.
Use the `-Z` option to provide the list of ZooKeeper nodes.

**NOTE:**

If the initial setting was based on the IP address, run `configure.sh` on all the ZooKeeper, CLDB, and Data nodes in the cluster.

If the initial setting was based on the hostname, there is no need to run `configure.sh` on any nodes when you change the IP address.

8. If you run the Drillbit service on any nodes in the cluster:
 - a) Change the ZooKeeper address in the `conf/drill-override.conf` file on the Drill nodes.
 - b) Start ZooKeeper on the ZooKeeper node, and then perform a rolling restart of ZooKeeper on all other ZooKeeper nodes.
A rolling restart of ZooKeeper means restart ZooKeeper on each node, one at a time, pausing until the last restart finishes before beginning the next. Restart the ZooKeeper leader last.
9. Verify that the new node joined the ZooKeeper quorum.

```
service mapr-zookeeper status
```

10. Perform a rolling restart of Warden on all the nodes.
11. Check that all nodes appear in the output of the [node list](#) on page 2570 command. You might have to wait a few minutes until all nodes are registered before you get output from this command.

```
/opt/mapr/bin/maprcli node list -columns ip
```

Viewing Active Node Alarms

Describes how to view active node alarms using the Control System and the CLI.

Viewing Active Node Alarms in the Control System

Procedure

-  **NOTE:** The **Nodes** page is not available in the Kubernetes version of the Control System.

Log in to the Control System and:

- Click **Nodes** to view all the node alarms on the cluster in the **Active Alarms** pane.
- Go to the [node information page](#) to view alarms in the **Alarms** pane for the selected node.
- Click  (in the top navigation bar) to display the **Alarm Summary** page and select **Node Alarms** from the drop-down menu in the **All** alarms pane.
- Click **Overview** and select **Node Alarms** from the drop-down menu in the **Active Alarms** pane to view all the node alarms on the cluster.

You can:

- [View](#) alarm notes
- [Mute](#) an alarm
- [Dismiss](#) an alarm

Retrieving Active Node Alarms Using the CLI or REST API

About this task

The basic command to retrieve node alarms is:

```
maprcli alarm list -cluster <cluster name> -type node
```

For complete reference information, see [alarm list](#) on page 2298.

Allocating Memory for Nodes

Describes how the Warden allocates memory for nodes.

When you run `configure.sh` on a node, Warden allocates memory for the operating system, mfs service, Data Fabric Hadoop services, and applications using the settings in the `warden.conf` and the `warden.<servicename>.conf` file.

Warden allocates memory to the following components in the following order:

1. Operating system
2. mfs service
3. Data Fabric Hadoop services
4. Applications, such as YARN applications
5. If the node only runs file system, NFS for the HPE Data Fabric, and gateway, then 85% of all memory is allocated to file system.

NOTE: In general, modify the settings in the warden files only under certain circumstances. If you modify the values in `warden.conf` or `warden.<servicename>.conf` file, you must restart Warden. Otherwise, updated parameters will not be used to allocate resources.

Allocating Memory for the OS, file system, and Hadoop Services

Lists the parameters that control how Warden allocates memory for the OS, file system and the HPE Data Fabric Hadoop services.

Warden allocates memory to the operating system, file system, and HPE Data Fabric Hadoop services based on the following parameters:

Parameter	Default OS	file system	Hadoop Service(s)	Description
service.command.<os mfs servicename>.heapsize.percent	10	varies	varies	Defines the heap size percentage.
service.command.<os mfs servicename>.heapsize.maxpercent	Not Applicable	85	Not Applicable	Defines the heap size maximum percentage
service.command.<os mfs servicename>.heapsize.max	4000	Not Applicable	5000	Defines the maximum heap size in MB.
service.command.<os mfs servicename>.heapsize.min	256	512	256	Defines the minimum heap size in MB.

Memory settings for the operating system and the file system are configured in the `warden.conf` file. The `warden.conf` file is located in `/opt/mapr/conf`. Other services, such as NodeManager and ResourceManager, have their own `warden.<servicename>.conf` file within `/opt/mapr/conf/conf.d`. For more information about the Warden files, see [warden.conf](#) and [warden.<servicename>.conf](#).

Note: Warden allocates resources only for the HPE Data Fabric Hadoop services associated with roles that are installed on the node.

Allocating Memory for the File System Service

Describes how Warden allocates memory for the file system service.

By default, Warden adds up the total memory consumed by all services and the OS, and then allocates 85% of the remainder to the file system. If you do not intend to use HPE Data Fabric Database, you can set the `-noDB` option in `configure.sh` to specify that 20% of the memory available should be allocated to the file system service. Allocating more memory to the file system improves performance due to greater data caching. Data caching is especially vital when your main constraint is disk I/O. For the parameters that you can configure to give Warden more memory, see [Allocating Memory for the OS, file system, and Hadoop Services](#) on page 1388.

Performing Maintenance on a Node from the Command-Line

Describes how to maintain the performance of a node using the CLI.

You can place a node into a maintenance mode for a specified timeout duration. For the duration of the timeout, the cluster CLDBs do not consider this node's data as lost and do not trigger a resync of the data on the node.

The following sections describe how to perform maintenance on a node.

Putting a Node into Maintenance Mode

Describes how to put a node into maintenance mode.

About this task

If you put a node into maintenance mode, the node is marked unserviceable, but is still attached to the cluster.

Before putting a node into maintenance mode, ensure that:

- All copies of the CLDB volume exist if the node is a CLDB node. You must stop the CLDB service running on the master node, before you can put a master node into maintenance mode. You can stop the CLDB service only if you have enabled high availability for CLDB.

You *cannot* put a node into maintenance mode if the node is running as the CLDB master and supports file-system services.

To put any node other than the master node into maintenance mode, you can directly run the [node maintenance](#) on page 2590 command on the respective node.

- All running processing tasks (NodeManager and Spark, for example) that depend on the file system have been stopped.

 **WARNING:** Do not put a node under maintenance if there are any volume under-replicated alarms because doing so might take some data completely offline.

To put a node into maintenance mode, perform the following actions:

Procedure

1. From a terminal, issue the [node maintenance](#) on page 2590 command:

```
/opt/mapr/bin/maprccli node maintenance -nodes <IP|
hostname> -timeoutminutes <minutes>
```

If you run this command, specify a timeout (in minutes) long enough for you to perform necessary maintenance on the node.

NOTE: For the duration of the timeout, the cluster CLDB considers this node as unavailable. Under this scenario, the CLDB does not trigger data replication for this node until it exits maintenance mode. Furthermore, clients accessing containers on the node receive the appropriate error and retry other container copies. Note also that if a node is put under maintenance for more than five minutes, the file system shuts down on that node to prevent any other operations from occurring. This value of five minutes is hard-coded and cannot be changed. Even if you reboot the node, the maintenance mode persists until the timeout is reached.

2. Stop Warden on the node:

```
service mapr-warden stop
```

To bring the node back online, see [Taking a Node Out of Maintenance Mode](#) on page 1389.

Taking a Node Out of Maintenance Mode

Describes how to bring a node back online from maintenance mode.

About this task

To take a node out of maintenance mode before the timeout expires, follow this process:

Procedure

1. From a terminal, issue the following command:

```
maprccli node maintenance -nodes <IP address> -timeoutminutes 0
```

2. Restart Warden:

```
service mapr-warden restart
```

Managing Roles

Describes how to manage roles on a node.

You must install [roles](#) on nodes in a cluster before their corresponding services can be launched. For information on how to install roles on nodes, see [Adding Roles to a Node](#). Refer to the following topics for managing the roles using the CLI.

Adding Roles to a Node

Summarizes the process to add a role.

You can add a [role](#) on a node after you deploy the node in a cluster. The process of adding a [role](#) to a node involves installing a package on the node and updating the cluster to recognize the new [role](#). The process of adding a [role](#) depends on the [role](#) type.

Once you have added a [role](#) to a node, you must restart Warden. Observe the following best practices when restarting Warden on ZooKeeper and CLDB nodes:

- Perform a rolling restart of Warden to ensure that all services are up. A rolling restart of Warden means restart Warden on each node, one at a time, pausing until the previous restart finishes, before beginning the next.
- To avoid a failover from occurring, identify nodes running critical services, such as ResourceManager, and restart Warden last on those nodes.
- Restart Warden on nodes that run critical cluster services, such as ResourceManager, during periods of low activity.

Adding a Role

Describes how to add various roles to a Data Fabric node.

About this task

Do not use these steps to add the CLDB or ZooKeeper role.

NOTE: When Collectd is installed on a node with YARN ResourceManager or NodeManager, running `configure.sh -R`, to add or remove roles on the node, triggers these services to restart. During a restart, the NodeManager and ResourceManager are temporarily unavailable for new application submission. A patch is available to resolve this behavior. See [Applying Patches](#).

The following steps describe how to add a role to a node:

Procedure

1. Install the package corresponding to the new role using `apt-get`, `yum`, or `zypper`, depending on your platform. For more information, see [Data Fabric Repositories and Packages](#) on page 152.
2. Run `configure.sh -R` on the node where you added the role.
If Warden is running, the new service starts automatically.

3. If you added the File server role, run `disksetup` to format and prepare disks for use as storage.
4. Issue the following command to restart Warden on the node where you installed the role:

```
% service mapr-warden restart
```

Adding a CLDB Role Using the CLI

Describes how to add a CLDB role to an HPE Data Fabric node using the CLI.

About this task

Complete the following steps to add the CLDB role to a node in the cluster:

Adding a CLDB Role to a Node on a Secure Cluster

Procedure

1. Install the CLDB package, `mapr-clldb`, on the node by using `apt-get`, `yum`, or `zypper` commands, depending on your operating system.
2. Copy the following files from the `/opt/mapr/conf` directory on any existing CLDB node on the cluster to the `/opt/mapr/conf` directory on this node.
 - `maprhsm.conf`
 - `maprkeycreds.conf`
 - `maprkeycreds.jceks`
 - `maprserverticket`
 - `maprtrustcreds.conf`
 - `maprtrustcreds.jceks`
 - `ssl_keystore`
 - `ssl_keystore.p12`
 - `ssl_keystore.pem`
 - `ssl_keystore-signed.pem`
 - `ssl_truststore`
 - `ssl_truststore.p12`
 - `ssl_truststore.pem`
 - `ssl_userkeystore`
 - `ssl_userkeystore.p12`
 - `ssl_userkeystore.pem`
 - `ssl_userkeystore-signed.pem`
 - `ssl_usertruststore`
 - `ssl_usertruststore.p12`

- `ssl_usertruststore.pem`
 - tokens (use a command such as `scp -r` to copy everything in this folder)
3. Run `configure.sh` on page 3186 with the following options on the node where you added the new CLDB role.
 - `-secure`: Use this option to enable the node for security.
 - `-C`: Use this option to include this node in the list of CLDB nodes. If Warden is running, the CLDB service starts automatically.
 - `-dare`: Use this option only if the cluster is enabled for data-at-rest encryption. Do not specify `-dare` if the cluster is not enabled for data-at-rest encryption.
 - Use one of the following to configure the list of ZooKeeper nodes:
 - `-R`: Use this option if the node is an existing cluster node. This option uses the previously configured list of ZooKeeper nodes. When `-R` is specified, the ZooKeeper credentials are read from `warden.conf` file.
 - `-Z`: Use this option if the node is a new node on the cluster. This option specifies the list of ZooKeeper nodes.
 4. Run `configure.sh` on page 3186 with the following options on all other nodes in the cluster.
 - `-C`: Use this option to include the new CLDB node in the list of CLDB nodes.
 - `-R`: Use this option to use the previously configured list of ZooKeeper nodes.
 5. Verify that the node has a CLDB role by running the following command:

```
maprcli node listcl dbs
```

The output should show all the CLDB nodes, including the node where the role was added.

Adding a ZooKeeper Role

Describes how to add a ZooKeeper role to a Data Fabric node by using the CLI.

About this task

This procedure adds one additional ZooKeeper to a previously installed cluster and uses rolling restarts to avoid cluster outages. If multiple additional ZooKeeper instances need to be added, repeat this procedure from start to finish for each new ZooKeeper.

While it is possible to use a modified version of this procedure to add multiple additional ZooKeepers at once, doing so involves more complexity and carries increased risk of creating a cluster outage if incorrect steps are followed.

Procedure

1. On each previously installed node, identify the state of the ZooKeeper service:

```
/opt/mapr/initscripts/zookeeper qstatus
```

All previously installed ZooKeeper services must be running and in either the leader or follower state. Do not proceed further until all previously installed ZooKeeper services are running as expected.

2. Install the ZooKeeper package on the new node. For more information about packages, see [Data Fabric Repositories and Packages](#) on page 152.
3. Copy the tokens and all other directories needed from a previously installed node to the new node. You can find the list of files you need to copy in [Enabling Security on a Configured Cluster](#) on page 2048.

IMPORTANT: Copying files while logged on as the root user results in the files being unreadable. Make sure the copied files have identical ownership and permissions between the previously installed node and the new node.

4. On all nodes in the cluster, run [configure.sh](#) on page 3186 with the following options:
 - -Z: Specify all previously installed ZooKeeper nodes and the new node.
 - -R: Specify this option to use all previously set configurations.

For example:

```
/opt/mapr/server/configure.sh -Z <all-nodes-including-new-one> -R
```

To identify the list of current ZooKeeper nodes in the cluster, run `maprcli node listzookeepers`.

5. Perform a rolling restart of Warden on all nodes. This step must be done before the ZooKeeper service is started on the new node as it is possible the new node becomes the leader, in which case, other cluster services would be unaware of where to find the leader.

Run the following command on all nodes to restart Warden:

```
systemctl restart mapr-warden
```

6. Perform a rolling restart of the ZooKeeper services on the previously installed and new nodes. Use the following command to restart the ZooKeeper service:

```
systemctl restart mapr-zookeeper
```

For each previously installed ZooKeeper node, one by one, restart the ZooKeeper service and then wait until the state is shown as either leader or follower before proceeding to the next node. Do not proceed to the next node until the state is shown as expected.

After all previously installed ZooKeeper services have been restarted, start the ZooKeeper service on the new node.

7. Confirm that the state of the ZooKeeper service on all nodes shows as either leader or follower.
8. Run `maprcli node listzookeepers`. The output should show all ZooKeeper nodes, including the node where the role was added.

Removing Roles from a Node

Describes how to remove a role from a node.

You can remove [roles](#) from nodes in the Data Fabric cluster. The process of removing a [role](#) from a node depends on the [role](#) type.

Once you remove a [role](#) from a node, you must restart Warden. Observe the following best practices when restarting Warden on nodes that were ZooKeeper or CLDB nodes:

- Perform a rolling restart of Warden to ensure that all services are up. A rolling restart of Warden means restart Warden on each node, one at a time, pausing until the previous restart finishes, before beginning the next.

- To avoid a failover from occurring, identify nodes running critical services, such as ResourceManager, and restart Warden last on those nodes.
- Restart Warden on nodes that run critical cluster services, such as ResourceManager, during periods of low activity.

Removing a Role

Describes how to remove a role from a node, using the CLI.

About this task

Do not use these steps to remove the CLDB, ZooKeeper, or Fileserver role from a node.

NOTE: When collectd is installed on a node with YARN ResourceManager or NodeManager, running `configure.sh -R`, to add or remove roles on the node, triggers these services to restart. During a restart, the NodeManager and ResourceManager are temporarily unavailable for new application submission. A patch is available to resolve this behavior. See [Applying Patches](#).

The following steps describe how to remove a role from a node:

Procedure

1. If you are removing the NFS role, unmount any existing client mounts.
Removing the NFS role from a node affects any Virtual IP (VIP) pools that include this node.
2. If the cluster has only one CLDB, run `configure.sh` with the `-C` option on all the nodes.
3. Stop the service for the role you want to remove, either through the Control System or by issuing a `maprccli` command:

```
% maprccli node services -name <service_name> -action stop -nodes
<node-name>
```

The following example stops the webserver role on node "my-node":

```
% maprccli node services -name webserver -action stop -nodes my-node
```

4. Purge the role packages with the `apt-get`, `yum`, or `zypper` commands, depending on your operating system.
5. Run `configure.sh -R` on the node where you removed the role.
Warden picks up the new configuration automatically.
6. Issue the following command to restart Warden on the node where you removed the role:

```
% service mapr-warden restart
```

Removing a CLDB Role

Describes how to remove the CLDB role from a node.

About this task

Procedure

1. If you have only one CLDB node in the cluster, add the CLDB role to another node.
When failover occurs after removal of the CLDB node, the new CLDB node becomes the primary CLDB.

2. Issue the following command to stop the CLDB service on the node:

```
/opt/mapr/bin/maprcli node services -name cldb -action stop -nodes
mapr-<node>
```

3. Purge the CLDB package, `mapr-cldb`, with the `apt-get`, `yum`, or `zypper` commands, depending on your operating system.
4. Run `configure.sh` on page 3186 with the `-C`, `-N` and `-Z` options on the node where you removed the role.
Use the `-C` option to provide the list of CLDB nodes, excluding the node where you removed the role, `-N` to pass the name of the cluster, and `-Z` to specify the list of ZooKeeper nodes.
5. Run `configure.sh` on page 3186 with the `-C`, `-N` and `-Z` options on all other nodes in the cluster.
Use the `-C` option to provide the list of CLDB nodes, excluding the node where you removed the role, `-N` to pass the name of the cluster, and `-Z` to specify the list of ZooKeeper nodes.

Removing a ZooKeeper Role

Describes how to remove the ZooKeeper role from a node by using the CLI.

About this task

This procedure removes one ZooKeeper node from a previously installed cluster and uses rolling restarts to avoid cluster outages. If multiple ZooKeeper instances need to be removed, repeat this procedure from start to finish for each such ZooKeeper.

While it is possible to use a modified version of this procedure to remove multiple ZooKeepers at once, doing so involves more complexity and carries increased risk of creating a cluster outage if incorrect steps are followed.

Procedure

1. On each node, identify the state of the ZooKeeper service:

```
/opt/mapr/initscripts/zookeeper qstatus
```

All previously installed ZooKeeper services, other than the one being removed, must be running and in either the leader or follower state. Do not proceed further if the ZooKeeper services are not in the expected state.

2. On the node being removed, run the following command to stop ZooKeeper:

```
service mapr-zookeeper stop
```

3. On the node being removed, purge the `mapr-zookeeper` package.
4. On all nodes in the cluster, run `configure.sh` on page 3186 with the following options:
 - a. `-Z`: Specify all existing ZooKeeper nodes except the one being removed.
 - b. `-R`: Specify this option to use all previously set configurations.

For example:

```
/opt/mapr/server/configure.sh -Z <all-nodes-excluding-removed-one> -R
```

To identify the list of current ZooKeeper nodes in the cluster, run `maprccli node listzookeepers`.

5. On the remaining nodes, perform a rolling restart of the ZooKeeper services. Use the following command to restart the ZooKeeper services:

```
systemctl restart mapr-zookeeper
```

For each remaining ZooKeeper node, one by one, restart the ZooKeeper service and then wait until its state is shown as either leader or follower before proceeding to the next node:

6. Perform a rolling restart of Warden. On all nodes, run the following command to restart Warden:

```
systemctl restart mapr-warden
```

7. Run `maprccli node listzookeepers`. The output should show only the remaining ZooKeeper nodes.

Removing a Fileserver Role

Describes how to remove the Fileserver role from a node.

About this task

Removing the fileserver role from a node is more complex than removing other roles. The CLDB tracks data precisely on all fileserver nodes, and therefore you should direct the cluster CLDB to stop tracking the node before removing the fileserver role. For a planned decommissioning of a node, use node topologies to migrate data off the node before removing the fileserver role. For example, you could move the node out of a live /data topology into a /decommissioned topology that has no volumes assigned to it, in order to force data off the node. Otherwise, some data will be under-replicated as soon as the node is removed. Refer to [Node Topology](#).

NOTE: The following procedure involves halting all Data Fabric services on the node temporarily. If this might disrupt critical services on your cluster, such as CLDB, migrate those services to a different node first, and then proceed.

The following steps describe how to remove the fileserver role from a node:

Procedure

1. Stop the warden, which will halt all Data Fabric services on the node. Wait 5 minutes, after which the CLDB will mark the node as critical.
2. Remove the node from the cluster, to direct the CLDB to stop tracking this node.
You can do this in the Control System GUI or with the `maprccli node remove` command.
3. Remove the fileserver role by deleting the file `/opt/mapr/roles/fileserver` on the node.
4. Run `configure.sh` on the node to reconfigure the node without the fileserver role.
5. Issue the following command to restart Warden on the node:

```
% service mapr-warden restart
```

6. Remove any volumes that were stored locally on the node.

You can do this in the Control System or with the `maprcli volume remove` command.

Assigning Roles to Nodes for Best Performance

Guidelines to optimise the cluster's service layout for best performance.

The architecture of Data Fabric software allows virtually any service to run on any node, or nodes, to provide a high-availability, high-performance cluster. The following guidelines help plan your cluster's service layout.

Do not Overload ZooKeeper

High latency on a ZooKeeper node can lead to an increased incidence of ZooKeeper quorum failures. A ZooKeeper quorum failure occurs when the cluster finds too few copies of the ZooKeeper service running. If the ZooKeeper node is also running other services, competition for computing resources can lead to increased latency for that node. If your cluster experiences issues relating to ZooKeeper quorum failures, consider reducing or eliminating the number of other services running on the ZooKeeper node.

Separate High-Demand Services

The following guideline states the services to separate on large clusters:

- **ResourceManager on ZooKeeper nodes:** Avoid running the ResourceManager service on nodes that are running the ZooKeeper service. On large clusters, the ResourceManager service can consume significant resources.

Managing Services

Synopsis on managing services.

Once a role is installed on a node and the warden has been restarted, HPE Data Fabric recognizes the role for that node. You can then start the service. Refer to the following topics for information on managing services on a node using the Control System and the CLI.

Viewing the List of Services

Explains how to view the list of services using either the Control System or the CLI.

Viewing the Services Installed on the Cluster Using the Control System

Procedure

- Log in to the Control System and click **Services**.

The **Services** pane displays all the services installed on the cluster. On the non-Kubernetes version of the Control System, the pane displays the following:

Column Name	Column Description
Service	The name of the installed service.
Running Nodes	The number of nodes on which the associated service is running. The service can be stopped (■) or restarted (↺). Click the number in this column to view the nodes on which the service is running.
Standby Nodes	The number of nodes on which the associated service is in standby (available, but not running) state. The service can be started (▶) or restarted (↺). Click the number in this column to view the nodes on which the service is in standby state.

Column Name	Column Description
Failed Nodes	The number of nodes on which the service has failed. The service can be started (▶) or restarted (↺). Click the number in this column to view the nodes on which the service has failed.
Stopped Nodes	The number of nodes on which the associated service is stopped (and not running). The service can be started (▶) or restarted (↺). Click the number in this column to view the nodes on which the service has been stopped.
Log Viewer	(Displays only if Kibana is installed on a node) The link (🔗) to the Kibana UI.

You can filter the list of services displayed by:

- **EEP**, which includes services such as Hive, Drill, etc.
- **Core**, which includes services such as CLDB, Hoststats, File server, etc.
- **Monitoring**, which includes services such as Grafana, Kibana, etc.

Viewing the Services Running on a Node Using the Control System

Procedure

1. Log in to the Control System and click **Nodes**.

NOTE: The **Nodes** menu is not available in the Kubernetes version of the Control System.

2. You can:
 - Hover the cursor over the number listed in the **Running Services** column in the **Nodes** pane to view the list of services installed on that node.
 - Go to the **Summary** tab in the [node information page](#) to view detailed information on the services installed on a node.

In the **Summary** tab, for each service running on the node, the **Services** pane displays the following:

Column Name	Column Description
Service	The name of the service.
State	The current state of the service. Value can be: <ul style="list-style-type: none"> • Running • Stopped
Memory Allocated	The amount of system memory allocated to the service.
System Memory Utilized	The percentage of memory utilized by the service.
CPU Usage	The CPU used by the service.
Log Path	The path to the service log file.
Log Viewer	The link to the Kibana UI (only if Kibana is installed).

You can select the checkbox beside one or more services to take the following actions:

- [Start Services](#)

- [Stop Services](#)
- [Restart Services](#)

NOTE: If Kibana is installed, you can click  to view the logs. See [Kibana User Guide](#) for more information.

Retrieving the Services Running on a Node Using the CLI or REST API

About this task

The command to list all the services on a node is:

```
maprcli service list -node <node name>
```

For complete reference information, see [service list](#) on page 2695.

Enabling and Disabling a Service Using the CLI and REST API

Describes how to enable or disable a service using either the REST API or the CLI.

About this task

You can disable a service to prevent it from starting or restarting when Warden starts or restarts, and enable a service to allow it to start or restart when Warden starts or restarts.

Disabling a Service Using the CLI or REST API

About this task

CLI

Run the following command:

```
maprcli node
services -nodes <hostName> -name
<serviceName> -action disable
```

REST

Send a request of type POST. For example:

```
curl -X POST 'https://
<host>:8443/rest/node/services?
nodes=<hostName>&name=<serviceName>
&action=disable' --user
<username>:<password>
```

NOTE: When you disable a service, the service is stopped and the service is not automatically started/restarted when Warden is started/restarted.

See [node services](#) on page 2598 for more information.

Enabling a Service Using the CLI or REST API

About this task

CLI

Run the following command:

```
maprcli node
services -nodes <hostName> -name
<serviceName> -action enable
```

REST

Send a request of type POST. For example:

```
curl -X POST 'https://
<host>:8443/rest/node/services?
nodes=<hostName>&name=<serviceName>
&action=enable' --user
<username>:<password>
```

NOTE: When you enable a service, the service is started/restarted when Warden is started/restarted.

See [node services](#) on page 2598 for more information.

Related tasks

[Restarting the Services](#) on page 1402

Describes how to restart a service using either the Control System, the CLI or the REST API.

Starting the Services

Explains how to start services using either the Control System, the CLI or the REST API.

About this task

You can start one or more services using the Control System or the CLI if the service is not disabled. If the service is disabled, you must enable the service first, in order to start the service. See [Enabling and Disabling a Service Using the CLI and REST API](#) on page 1399 for more information.

Starting the Services Running on the Nodes Using the Control System**About this task**

To start the services running on the nodes:

Procedure

1. Log in to the Control System and click **Nodes** to display the **Nodes** page.

NOTE: The **Nodes** page is not available on the Kubernetes version of the Control System.

2. Select the nodes from the list of nodes in the **Nodes** pane and click **Manage Services** to display the **Manage Services** window.
3. Choose the **Start** radio button for the services you wish to start on the selected nodes and click **Save**.

Starting the Services Running on a Node Using the Control System**About this task**

To start one or more services running on a node:

Procedure

1. Go to the **Summary** tab in the [node information page](#).
2. Select the services to start in the **Services** pane.
3. Click **Start Services**.
The **Start Services** confirmation dialog displays.
4. Verify the list of services to start and click **Start Service**.

Starting the Services on the Cluster Using the Control System

Procedure

1. Log in to the Control System and click **Services** to display the list of services on the cluster.
2. On the non-Kubernetes version of the Control System, click  for the service to start. The **Start Service** confirmation dialog displays.
3. Verify the list of nodes on which to start the service and click **Start Service**.

Starting a Service Using the CLI or REST API

About this task

The basic command to start a service on a node is:

```
maprcli node services -nodes <node name> -name <service> -action start
```

For complete reference information, see [node services](#) on page 2598.

Stopping the Services

Describes how to stop services using either the Control System, the CLI or the REST API.

Stopping the Services Running on the Nodes Using the Control System

About this task

To stop the services running on the nodes:

Procedure

1. Log in to the Control System and click **Nodes** to display the **Nodes** page.
-  **NOTE:** The **Nodes** page is not available in the Kubernetes version of the Control System.
2. Select the nodes from the list of nodes in the **Nodes** pane and click **Manage Services** to display the **Manage Services** window.
3. Choose the **Stop** radio button for the services you wish to stop on the selected nodes and click **Save**.

Stopping the Services on a Node Using the Control System

About this task

To stop one or more services running on a node:

Procedure

1. Go to the **Summary** tab in the [node information page](#).
2. Select the services to stop in the **Services** pane.
3. Click **Stop Services**.
The **Stop Services** confirmation dialog displays.
4. Verify the list of services to stop and click **Stop Service**.

Stopping a Service on the Cluster Using the Control System

Procedure

1. Log in to the Control System and click **Services**.
2. On the non-Kubernetes version, click  associated with the service to stop. The **Stop Service** confirmation dialog displays.
3. Verify the list of nodes on which to stop the service and click **Stop Service**.

Stopping the Services Using the CLI or REST API

About this task

The basic command to stop a service on a node is:

```
maprcli node services -nodes <node name> -name <service> -action stop
```

For complete reference information, see [node services](#) on page 2598.

Restarting the Services

Describes how to restart a service using either the Control System, the CLI or the REST API.

About this task

When a HPE Data Fabric system is rebooted, the following services are automatically restarted:

- mapr-warden
- mapr-zookeeper
- mapr-loopbacknfs
- mapr-posix-client-*

These services are also automatically restarted if they are shut down externally (as opposed to being shut down explicitly via `service` or `sysctl` commands).

NOTE: This feature is implemented with `systemd` and is only supported on the following operating systems:

- RHEL 7.0, 7.1
- CentOS 7.0, 7.1
- SLES 12

This feature is not supported on any of the Ubuntu versions that HPE Data Fabric currently supports.

You can restart one or more services using the Control System and the CLI if the services are not disabled. However, if a service is disabled, the service cannot be restarted. To restart a service, make sure the service is enabled. See [Enabling and Disabling a Service Using the CLI and REST API](#) on page 1796 for more information.

Restarting the Services Running on the Nodes Using the Control System

About this task

To restart the services running on the nodes:

Procedure

1. Log in to the Control System and click **Nodes** to display the **Nodes** page.

NOTE: The **Nodes** page is not available on the Kubernetes version of the Control System.

2. Select the nodes from the list of nodes in the **Nodes** pane and click **Manage Services** to display the **Manage Services** window.
3. Choose the **Restart** radio button for the services you wish to restart on the selected nodes and click **Save**.

Restarting one or more Services on a Node Using the Control System**Procedure**

1. Go to the **Summary** tab in the [node information page](#).
2. Select the services to restart in the **Services** pane.
3. Click **Restart Service(s)**.
The **Restart Service(s)** confirmation dialog displays.
4. Verify the list of services to restart and click **Restart Service**.

Restarting the Services on the Cluster Using the Control System**Procedure**

1. Log in to the Control System and navigate to **Services**.
2. On the non-Kubernetes version, click  associated with the service to restart.
The **Restart Service** confirmation dialog displays.
3. Verify the list of nodes on which to restart the service and click **Restart Service**.

Restarting a Service Using the CLI or REST API**About this task**

The basic command to restart a service on a node is:

```
maprcli node services -nodes <node name> -name <service> -action restart
```

For complete reference information, see [node services](#) on page 2598.

Related tasks

[Enabling and Disabling a Service Using the CLI and REST API](#) on page 1796
Describes how to enable or disable a service using either the REST API or the CLI.

Changing the User for Data Fabric Services from the Command-Line

Explains how use the CLI to change the user that Data Fabric services run as.

About this task

All services should run with the same uid/gid on all nodes in the cluster.

Running Data Fabric Services as the Root User

Procedure

1. Stop Warden.

```
service mapr-warden stop
```

2. If ZooKeeper is installed on the node, stop it.

```
service mapr-zookeeper stop
```

3. Run the script `$INSTALL_DIR/server/config-mapr-user.sh -u root`

4. If Zookeeper is installed, start it.

```
service mapr-zookeeper start
```

5. Start Warden.

```
service mapr-warden start
```

Running Data Fabric Services as a Non-Root User

Procedure

1. Stop Warden.

```
service mapr-warden stop
```

2. If ZooKeeper is installed on the node, stop it.

```
service mapr-zookeeper stop
```

3. If the `MAPR_USER` does not exist, create the user/group with the same UID and GID.

4. If the `MAPR_USER` exists, verify that the uid of `MAPR_USER` is the same as the value on the CLDB node.

5. Run `$INSTALL_DIR/server/config-mapr-user.sh -u MAPR_USER`.

6. If Zookeeper is installed, start it.

```
service mapr-zookeeper start
```

7. Start Warden.

```
service mapr-warden start
```

8. After clearing `NODE_ALARM_MAPRUSER_MISMATCH` alarms on all nodes, run `$INSTALL_DIR/server/upgrade2mapruser.sh` on all nodes wherever the alarm is raised.

Running Data Fabric Services as the Root User

Procedure

1. Stop Warden:

```
service mapr-warden stop
```

2. If ZooKeeper is installed on the node, stop it:

```
service mapr-zookeeper stop
```

3. Run the script `$INSTALL_DIR/server/config-mapr-user.sh -u root`

4. If ZooKeeper is installed, start it:

```
service mapr-zookeeper start
```

5. Start Warden:

```
service mapr-warden start
```

Running Data Fabric Services as a Non-Root User

Procedure

1. Stop Warden:

```
service mapr-warden stop
```

2. If ZooKeeper is installed on the node, stop it:

```
service mapr-zookeeper stop
```

3. If the `MAPR_USER` does not exist, create the user/group with the same UID and GID.

4. If the `MAPR_USER` exists, verify that the uid of `MAPR_USER` is the same as the value on the CLDB node.

5. Run `$INSTALL_DIR/server/config-mapr-user.sh -u MAPR_USER`

6. If Zookeeper is installed, start it:

```
service mapr-zookeeper start
```

7. Start Warden:

```
service mapr-warden start
```

8. After clearing `NODE_ALARM_MAPRUSER_MISMATCH` alarms on all nodes, run `$INSTALL_DIR/server/upgrade2mapruser.sh` on all nodes wherever the alarm is raised.

Managing Disks

Provides a brief overview of adding and removing disks from the HPE Data Fabric file system.

You can add and remove disks in the file system from the control system or using the `diskadd` and `diskremove` commands. file system groups disks into *storage pools*, usually made up of two or three disks. When adding disks to the file system, it is a good idea to add at least two or three at a time so that HPE Data Fabric can create properly-sized storage pools. Each node in a HPE Data Fabric cluster can support up to 36 storage pools.

To see which disks are used by file system, check the `disktab` file that HPE Data Fabric maintains on each node.

 **WARNING:** For instructions on performing disk maintenance on a node, see [Performing Maintenance on a Node](#). If a disk failure alarm is raised (NODE_ALARM_DISK_FAILURE), see [Handling Disk Failures](#) for instructions.

Refer to the following procedures to manage disks using the Control System and the CLI.

Viewing the List of Disks

Explains how to view the disks on a node using either the Control System or the CLI.

Viewing the List of Disks Using the Control System

About this task

To view both the system and filesystem disks:

Procedure

1. Log in to the Control System and go to the [node information page](#).
2. Go to the **Summary** tab.

On this page, the **Disks** and **System Disks** panes display the following for each disk:

Column Name	Column Description
Status	The status of the disk. Value can be one of the following: <ul style="list-style-type: none"> ✓ — indicates disk is active or good. ⏻ — indicates disk is on standby. ⏻ — indicates disk is offline.
Device	The disk partition(s).
Mnt	Indicates whether (✓) or not the disk is mounted.
file system	(Displayed in the Disks pane only) The disks available for file system. A ✓ indicates that the disk was added to file system.
File System	(Displayed in the System Disks pane only) The disks for system use.
Allocated	The amount of space allocated, in gigabytes.
Used	The percentage of disk space used.
Model#	The disk model number.
Firmware Version	The disk firmware version.
Storage Label	The label assigned to the disk.

Column Name	Column Description
Storage Pool	The ID of the storage pool associated with the disk.

Select the checkbox beside a disk in the **Disks** pane to:

- [Add Disk\(s\) to file system](#)
- [Remove Disk\(s\) from file system](#)

NOTE: Disks in the **System Disks** pane cannot be selected.

Retrieving the List of Disks Using the CLI or REST API

About this task

The basic command to list the disks on a node is:

```
maprcli disk list -host <host>
```

For complete reference information, see [disk list](#) on page 2422.

Setting Up Disks for HPE Data Fabric

This section describes how to set up disks during the normal installation process. Go to the [disksetup](#) on page 3230 command page for information about other uses of this command.

HPE Data Fabric formats and uses disks for the Lockless Storage Services layer (file system), and records these disks in the [disktab](#) on page 3365 file. In a production environment, or when testing performance, HPE Data Fabric should be configured to use physical hard drives and partitions. In some cases, it is necessary to reinstall the operating system on a node so that the physical hard drives are available for direct use by HPE Data Fabric. Reinstalling the operating system provides an unrestricted opportunity to configure the hard drives. If the installation procedure assigns hard drives to be managed by the Linux [Logical Volume Manager](#)(LVM) by default, you should explicitly remove the drives you plan to use with HPE Data Fabric from the LVM configuration. It is common to let LVM manage one physical drive containing the operating system partition(s) and to leave the rest unmanaged by LVM for use with HPE Data Fabric.

NOTE: It is not necessary to set up RAID (Redundant Array of Independent Disks) on disks used by file system. HPE Data Fabric uses the [disksetup](#) script to set up storage pools. In most cases, you should let HPE Data Fabric calculate storage pools using the default stripe width of two or three disks. If you anticipate a high volume of random-access I/O, you can use the `-w` option with [disksetup](#) to specify larger storage pools of up to 8 disks each.

NOTICE: For more information on setting up disks, see [Drive Configuration](#).

The following procedures are intended for use on physical clusters or Amazon EC2 instances. On EC2 instances, EBS volumes can be used as HPE Data Fabric storage, although performance will be slow.

NOTE: If you are using [HPE Data Fabric on Amazon EMR](#), you do not have to use this procedure; the disks are set up for you automatically.

Determine if a disk or partition is ready for use by HPE Data Fabric

Explains the procedure to determine whether a disk or partition is ready for use by HPE Data Fabric.

About this task

Any disk or partition that passes the following testing procedure can be added to the list of disks and partitions passed to the [disksetup](#) command.

1. Run the command `sudo lsof <partition>` to determine whether any processes are already using the disk or partition.
There should be no output when running `sudo fuser <partition>`, indicating there is no process accessing the specific disk or partition.
2. The disk or partition should not be mounted, as checked via the output of the `mount` command. If the disk or partition is mounted, unmount it using the `umount` command.
3. The disk or partition should not have an entry in the `/etc/fstab` file; comment out or delete any such entries.
4. The disk or partition should be accessible to standard Linux tools such as `mkfs`. You should be able to successfully format the partition using a command like `sudo mkfs.ext3 <partition>` as this is similar to the operations that HPE Data Fabric performs during installation. If `mkfs` fails to access and format the partition, then it is highly likely that HPE Data Fabric will encounter the same problem.

Specify disks or partitions for use by HPE Data Fabric

Describes the use of the `disksetup` script to format disks.

About this task

The `disksetup` script is used to format disks for use by the HPE Data Fabric cluster. Create a text file `/tmp/disks.txt` listing the disks and partitions for use by HPE Data Fabric on the node. Each line lists either a single disk or all applicable partitions on a single disk. When listing multiple partitions on a line, separate by spaces. For example:

```
/dev/sdb
/dev/sdc1 /dev/sdc2 /dev/sdc4
/dev/sdd
```

Later, when you run the `disksetup` script to format the disks, specify the `disks.txt` file. For example:

```
/opt/mapr/server/disksetup -F /tmp/disks.txt
```

NOTE: The `disksetup` script removes all data from the specified disks. Make sure you specify the disks correctly, and that any data you wish to keep has been backed up elsewhere.

If you are re-using a node that was used previously in another cluster, be sure to format the disks to remove any traces of data from the old cluster.

NOTE: Run the `disksetup` script only after running the `configure.sh` script.

Evaluate HPE Data Fabric using a flat storage file instead of formatting disks

For evaluation, you can use a flat storage file instead of formatting disks.

About this task

When setting up a small cluster for evaluation purposes, if a particular node does not have physical disks or partitions available to dedicate to the cluster, you can use a flat file on an existing disk partition as the node's storage. Create at least a 16GB file, and include a path to the file in the disk list file for the `disksetup` script.

The following example creates a 20 GB flat file (`bs=1G` specifies 1 gigabyte blocks, multiplied by `count=20`) at `/root/storagefile`:

```
dd if=/dev/zero of=/root/storagefile bs=1G count=20
```

Add the created flat file to the disk list file `/tmp/disks.txt` to be used by `disksetup`:

```
/root/storagefile
```

Adding Disks to file system

Describes how to add disks using either the Control System or the CLI.

About this task

You can add disks to file system using the Control System and the CLI. Before adding the disks to file system, add the physical disks to the node or nodes according to the correct hardware procedure.

- If you are removing and replacing failed disks, you must install the replacements, then re-add the replacement disks to file system, along with the other disks that were in the same storage pool(s) as the failed disks. See [Handling Disk Failures](#) for more details.
- If you are removing disks but not replacing them, you can just re-add the other disks that were in the same storage pool(s) as the failed disks.

NOTE: Disks must be added on CLDB nodes one node at a time when Warden and HPE Data Fabric services are running.

ATTENTION: Disable write caching on all HPE Data Fabric disks if the disks are not battery backed.

Adding Disks Using the Control System

About this task

Complete the following steps to add disks of type file system using the Control System:

Procedure

1. Log in to the Control System and go to the **Summary** tab in the [node information page](#).

NOTE: The **Nodes** page is not available on the Kubernetes version of the Control System.

2. Select the disks not yet added to file system in the **Disks** pane and click **Add Disks to File System**. The **Add Disks to File System** confirmation dialog displays.

NOTE: You cannot select disks of type *System* to add.

3. Review the list and click **Add Disk**.
The disks are automatically formatted and properly-sized storage pools are automatically allocated.

Adding Disks Using the CLI or REST API

About this task

The basic command to add disks to a node is:

```
maprcli disk add -disks <disk names> -host <host>
```

NOTE: This step reformats the disks. Any data on these disks will be lost.

For complete reference information, see [disk add](#) on page 2418.

Removing Disks from the File System

Explains how to remove disks using either the Control System or the CLI.

About this task

When you remove a disk from the file system, other disks in the storage pool are also removed automatically from the file system and are no longer in use (they are available but off-line). Their disk storage goes to 0%, and they are eligible to be added again to the file system to build a new storage pool. You can either replace the disk and re-add it along with the other disks that were in the storage pool, or just re-add the other disks if you do not plan to replace the disk you removed. See [Adding Disks to file system](#) on page 1409 for more information.

 **WARNING:** Removing a disk in the storage pool that contains Container ID 1 shuts down CLDB, triggering a CLDB failover. Container ID 1 contains CLDB data for the primary CLDB. From the command-line, run the `maprc li disk remove` command without the `-force 1` option first and examine the warning messages to make sure you are not removing the disk with Container ID 1. To safely remove such a disk, perform a [CLDB Failover](#) on page 2243 to make one of the other CLDB nodes the primary CLDB, then remove the disk as normal with addition of the `-force 1` option.

Before removing or replacing disks, make sure the Replication Alarm (VOLUME_ALARM_DATA_UNDER_REPLICATED), Data Alarm (VOLUME_ALARM_DATA_UNAVAILABLE), Warm-Tier Data Node Down (VOLUME_ALARM_DEGRADED_EC_STRIPES), and EC Degraded Alarm (VOLUME_ALARM_CRITICALLY_DEGRADED_EC_STRIPES) are not raised. These alarms can indicate potential or actual data loss. If either alarm is raised, you might be able to repair the problem using the `/opt/mapr/server/fsck` utility before removing or replacing disks.

 **NOTE:** Using the `/opt/mapr/server/fsck` utility with the `-r` flag to repair a file system risks data loss. Call HPE Data Fabric support before using `/opt/mapr/server/fsck -r`.

Removing Disks from file system Using the Control System

About this task

Complete the following steps to remove disks using the Control System:

Procedure

1. Log in to the Control System and go to the **Summary** tab in the [node information page](#).
2. Select the disks to remove in the **Disks** pane and click **Remove Disk(s) from File System**. The **Remove Disk(s) from File System** confirmation dialog displays.

 **WARNING:** One or more disks you selected may have unreplicated data on it and this action will forcefully remove the disks.

3. Review the list and click **Remove Disk**.
Wait several minutes while the removal process completes. After you remove the disks, any other disks in the same storage pools are taken offline and marked as *available* (not in use by HPE Data Fabric).
4. Remove the physical disks from the node or nodes according to the correct hardware procedure.
5. From a command line terminal, remove the failed disk log file from the `/opt/mapr/Logs` directory. These log files are typically named like this:

```
diskname.failed.info
```

Removing Disks from file system Using the CLI or REST API

Procedure

1. On the node, determine which disk to remove/replace by examining **Disk** entries in the `/opt/mapr/logs/faileddisk.log` file.
2. Run the following command, substituting the hostname or IP address for `<host>` and a list of disks for `<disks>`

```
maprcli disk remove -disks <disk names> -host <host>
```

NOTE: This command does not remove a disk containing unreplicated data unless forced.

For complete reference information, see [disk remove](#) on page 2429.

3. Examine the screen output in response to the command you ran in step 2.
For example:

```
maprcli disk remove -host `hostname -f` -disks /dev/sdd
message      host      disk
removed.    host1     /dev/sdd
removed.    host1     /dev/sde
removed.    host1     /dev/sdf
```

Make a note of the *additional* disks removed when the disk is removed. For example, the disks `/dev/sde` and `/dev/sdf` are part of the same storage pool and therefore removed along with the disk `/dev/sdd`.

4. Confirm that the removed disks do not appear in the `disktab` file.
5. Remove the disk log file from the `/opt/mapr/logs` directory.
For failed disks, these log files are typically named in the pattern `diskname.failed.info`.

What to do next

When you replace a failed disk, [add it back to the file system](#) along with the other disks from the same storage pool that were previously removed. Adding only the replacement disk to the file system, results in a non-optimal storage pool layout, which can lead to degraded performance.

Once you add the disks to the file system, the cluster automatically allocates properly-sized storage pools. For example, if you add ten disks, HPE Data Fabric allocates two storage pools of three disks each and two storage pools of two disks each.

Determining the Amount of Free Disk From the Command-Line

Lists the command to display the amount of free disk space.

To determine the amount of used and available disk space on the file system, run `df -h`. When running this command, if:

- The given path points to the mount point, the output will display used and available disk space for the entire cluster. For example:

```
[root@atsqa6c69 ~]df -h /mapr/clus.posix/
Filesystem      Size  Used Avail Use% Mounted on
posix-client-basic 4.4T  9.7G  4.4T   1%  /mapr
```

- The given path points to a volume with no (hard) quota, the output will display used and available disk space for the entire cluster. For example:

```
[root@atsqa6c69 ~]df -h /mapr/clus.posix/vol3
Filesystem      Size  Used Avail Use% Mounted on
posix-client-basic 4.4T  9.7G  4.4T   1%  /mapr
```

- The given path points to a volume with (hard) quota set, the output will display the used and available disk space for the specific volume based on the allocated quota. For example:

```
[root@atsqa6c69 ~]df -h /mapr/clus.posix/vol2/
Filesystem      Size  Used Avail Use% Mounted on
posix-client-basic 5.0G  2.5G  2.6G  49%  /mapr
```

Tolerating Slow Disks

Explains how to tune disk response timeouts.

The parameter `mfs.io.disk.timeout` in `mfs.conf` determines how long HPE Data Fabric waits for a disk to respond before assuming it has failed. If healthy disks are too slow, and are erroneously marked as failed, you can increase the value of this parameter.

Formatting Disks on a Node From the Command-line

Provides an overview of the `disksetup` script to format disks from the command line.

The `disksetup` script is used to format disks for use by the HPE Data Fabric cluster. Create a text file `/tmp/disks.txt` listing the disks and partitions for use by HPE Data Fabric on the node. Each line lists either a single disk or all applicable partitions on a single disk. When listing multiple partitions on a line, separate by spaces. For example:

```
/dev/sdb
/dev/sdc1 /dev/sdc2 /dev/sdc4
/dev/sdd
```

Later, when you run `disksetup` to format the disks, specify the `disks.txt` file. For example:

```
/opt/mapr/server/disksetup -F /tmp/disks.txt
```

NOTE: The `disksetup` script removes all data from the specified disks. Make sure you specify the disks correctly, and that any data you wish to keep has been backed up elsewhere.

If you are re-using a node that was used previously in another cluster, be sure to format the disks to remove any traces of data from the old cluster.

WARNING: Run `disksetup` only after running `configure.sh`.

Handling Disk Failures

Explains how to handle disk failures.

When a disk fails, Data Fabric raises the node-level alarm `NODE_ALARM_DISK_FAILURE` on the node with the failed disk (or disks). At the same time, other disks in the same storage pool as the failed disk are taken offline. You can look at the Control System **Overview** page to view the health of the nodes and a list of alarms.

When you see a disk failure alarm, examine the log file at `/opt/mapr/logs/faileddisk.log` and check the **Failure Reason** field.

Examining the Cause of Failure

Names the log file that contains the cause of disk failures.

In the `faileddisk.log` file, you will see information on the cause of failure. In the following sample log output, the failure reason is *I/O error*. Notice that the log file also provides instructions for removing disks and adding them back to the file system.

```
##### Disk Failure Report
#####
Disk           : /dev/sdd
Vendor         : [vendor]
Model Number   : [model]
Serial Number  : [serial]
Firmware Revision : [firmware]
Size           : [total]
Failure Reason  : I/O error
Time of Failure : Fri Jan 31 12:48:00 GMT 2014
Resolution     : Please refer to MapR's online documentation at
https://docs.datafabric.hpe.com on how to handle
disk failures.
In summary, run the following steps:
a. If this appears to be a software failure, go to step
b. Otherwise, physically remove the disk /dev/sdd. Optionally, replace it
with a new disk.
b. Run the command "maprcli disk remove -host 127.0.0.1 -disks /dev/sdd" to
remove
/dev/sdd from MapR-FS.
c. In addition to /dev/sdd, the above command removes all the disks that
belong to the same
storage pool, from MapR-FS. Note down the names of all removed
disks.
d. Add all the above removed disks (exclude /dev/sdd) and the new disk to
MapR-FS by
running the command:
"maprcli disk add -host 127.0.0.1 -disks <comma separated list of
disks>"
For example, If /dev/sdx is the new replaced disk, and /dev/
sdy, /dev/sdz were removed in
step c), the command would be:
"maprcli disk add -host 127.0.0.1 -disks /dev/sdx,/dev/sdy,/dev/
sdz" If there is no new disk, the command would just
be: "maprcli disk add -host 127.0.0.1 -disks
/dev/sdy,/dev/sdz"
```

Recovering from Disk Failure

Lists the disk errors and their resolution.

Most software failures can be remedied by running the [fsck](#) utility, which scans the storage pool to which the disk belongs and reports errors. For hardware failures, remove the failed disk and replace it according to the procedure in [Removing and Replacing Disks](#).

The following are the types of failures and the recommended courses of action:

I/OTimeout Error

Failure Reason: The default value for `mfs.disk.io.timeout` parameter is 60 seconds. The time to declare an IO as stuck is 3 times the value of this parameter (3 x `mfs.disk.io.timeout`). The disk will be taken offline even if a single IO has not completed.

Action:

1. Check if the disks are good and still reliable.

2. If disks are good, increase the value of the `mfs.io.disk.timeout` parameter in the `/opt/mapr/conf/mfs.conf` file. Otherwise, replace the disks.

No Such Device

Failure Reason: The `$INSTALL_DIR/conf/disktab` file contains `"/MissingDisk"` or references a disk path not found in `/proc/partitions` file.

Action: Run `mrdisk <device path>` to determine whether a disk is formatted for file system. Also, check the device paths in `$INSTALL_DIR/conf/disktab` file. The `disktab` file contains the disk path and disk GUID that is used to load the disks in the file system. If the disk paths have been renamed, fix them or run `disksetup -X` command to regenerate the `disktab` from `/proc/partitions`. Alternatively, restart the file system to resolve disk name changes.

If the problem still persists, contact HPE Data Fabric support.

ENODEV: MissingDisk# Error: disktab file contains a / MissingDisk# entry

Failure Reason: A disk corresponding to a GUID is missing and the corresponding disk path in the `disktab` file belongs to another disk. When an attempt is made to automatically fix the `disktab` file, this entry is replaced with `/MissingDisk#` path.

Action: If a disk corresponding to a GUID is permanently lost, remove the line corresponding to it in the `disktab` file. Alternatively, run `maprcli disk remove _MissingDisk#` command, where `#` corresponds to the disk number, and restart the file system.

EIO Error

Failure Reason: I/O error. This could be due to a bad block or disk. The system will offline the SP after one final attempt to complete the IO.

Action: Check `/var/log/messages` for errors from the disk drivers.

CRC Error

Failure Reason: This could be due to a bad block or bit flip on the disk. The SP will be taken offline immediately.

Action: Run `fsck -n <sp> -d` to perform a CRC (Cyclic Redundancy Check) on the data blocks in the storage pool, then bring it back online.

To load all the SPs to the list of SPs, run:

```
mrconfig disk load or mrconfig sp load
```

To bring back all SPs online, run:

```
mrconfig sp refresh
```

To bring specific SPs back online, run:

```
mrconfig sp online <sp path>
```

SlowDisk Error

Failure Reason: The default value for the `mfs.disk.io.timeout` parameter is 60 seconds.

The time to declare an IO as slow is equal to the value of this parameter (`1 x mfs.disk.io.timeout`). Thirty or more slow IO completions in a short span of time (5 seconds) on the same disk is recorded as a slow event. The SP will be taken offline if 3 such events are recorded within an hour.

NOTE: After an hour, HPE Data Fabric filesystem will reset tracking (to 0).

Action:

1. Check if the disks are good and still reliable.
2. If disks are good, increase the value of the `mfs.io.disk.timeout` parameter in the `/opt/mapr/conf/mfs.conf` file. Otherwise, replace the disks.

GUID of disk mismatches with the one in `$INSTALL_DIR/conf/disktab`

Failure Reason: Possible that disk names have changed.

Action: After a node restart, the operating system can reassign the drive labels (for example, `/sda`), resulting in drive labels no longer matching the entries in the `disktab` file. The `disktab` file contains the disk path and disk GUID that is used to load the disks in the file system. Run `$INSTALL_DIR/server/disksetup -X` to update the `disktab` file by looking up the disks in `/proc/partitions` and make the disk paths match the GUIDs.

Unknown Error

Failure Reason: Any reason

Action: Contact HPE Data Fabric support.

Addressing Data Alarms

Lists all the data alarms and their mitigation.

When a disk fails, data on that disk becomes unavailable. As a result, you will probably see one of these two data alarms along with a **Disk Failure** alarm:

- **Data Unavailable** (`VOLUME_ALARM_DATA_UNAVAILABLE`) - if there was only one copy of data and it was on the failed disk; or if data was replicated more than once, but all disks with that data failed
- **Data Under Replicated** (`VOLUME_ALARM_DATA_UNDER_REPLICATED`) - if data on the failed disk is replicated elsewhere, but the minimum replication factor is not met as a result of the failed disk

If you see a **Data Unavailable** volume alarm in the cluster, follow these steps to run the `/opt/mapr/server/fsck` utility on all the offline storage pools. On each node in the cluster that has raised a disk failure alarm:

1. Run the following command to identify which storage pools are offline:
[user@host] `/opt/mapr/server/mrconfig sp list | grep Offline`
2. For each storage pool reported by the previous command, run the following command, where `<sp>` specifies the name of an offline storage pool:
[user@host] `/opt/mapr/server/fsck -n <sp> -r`

When you run `fsck` with the `-r` option, it identifies corrupt blocks and removes them. If there are no corrupt blocks, `fsck` clears the error condition so you can bring the storage pool back online.

NOTE: Using the `/opt/mapr/server/fsck` utility with the `-r` flag to repair a filesystem risks data loss. Call support before using `/opt/mapr/server/fsck -r`.

3. Verify that all **Data Unavailable** volume alarms are cleared. If **Data Unavailable** volume alarms persist, contact support or post on answers.mapr.com.

If there are any **Data Under Replicated** volume alarms in the cluster, can repair the problem by automatically replicating data and putting it on another disk. After you allow a reasonable amount of time for re-replication, verify that the under-replication alarms are cleared.

Using the `/opt/mapr/server/fsck` utility with the `-r` option produces different results depending on the scenario. The `fsck` utility does not interpret the scenario nor does it have a safe mode.

- If a disk is offline because of an imbalanced b-tree, using `fsck -r` may result in data loss from bad containers and data loss if additional replicas are unavailable.
- If a disk is offline because of an I/O error, using `fsck -r` produces indeterminate results. A disk that is throwing I/O errors is questionable in terms of data content and reliability. For example, an operation that completed on the disk but was never returned may have partial data remaining on the disk. Using `fsck -r` retains any partial data.
- If a disk is offline because of a slow I/O, using `fsck -r` does not produce data loss.

The most conservative usage of `fsck -r` is to run `fsck` without the `-r` option (verification mode) and check the output. If the output is ok, then run `fsck` with the `-r` option.

NOTE: Disk Failure node alarms that persist require disk replacement. If **Data Under Replicated** volume alarms persist, contact support or post on answers.mapr.com.

Removing and Replacing Disks

If a disk fails due to a hardware problem, you will need to remove the disk. You can replace it, and then add that disk back to file system along with the other disks that were automatically removed at the same time.

Refer to the following for information on how to remove and replace disks using the Data Fabric command-line interface and the Control System:

- [Removing Disks from the File System](#) on page 1409
- [Adding Disks to file system](#) on page 1409

Designating NICs for HPE Data Fabric

Explains how to assign IP address blocks for HPE Data Fabric.

By default, file-system instances and the CLDB nodes advertise all the available IP addresses, and HPE Data Fabric automatically uses all available network interface cards (NICs) on each node for all communication. For nodes that have multiple NICs, HPE Data Fabric supports segregation of the NICs. Segregation enables certain IPs to be used for clients or communication within the cluster, and certain IPs can be used for clients or communication from outside the cluster. Also, NICs can be segregated for specific (high-performance and/or low-performance) clients within the cluster.

For example, if you use multiple NICs of mixed speeds (such as 1GbE and 10GbE) on each node, you might want to separate them to two different networks depending on the Ethernet card speeds. You can assign IP addresses in the same network to the NICs of 1GbE and assign IP addresses in another network to the NICs of 10GbE. In this way, you can use the faster NICs for communication within the cluster or for certain high-performance clients (for example, FUSE-based POSIX clients) and the slower NICs for external communication or for low-performance clients or jobs.

To illustrate this arrangement, the following diagram shows six nodes on an HPE Data Fabric cluster, each with a 1GbE NIC (eth0) and a 10GbE NIC (eth1). All the 1GbE NICs are networked together and connected to Network B. Likewise, all the 10GbE NICs are networked together (as part of a subnet written as 10.10.10.0/24 in CIDR notation) and connected to Network A, where peak performance is required. ClientA, which is within the cluster, communicates with cluster nodes over Network A. Clients outside the cluster communicate with cluster nodes over Network B.

The illustration also shows ClientB, which is a low-performance client inside the cluster, communicating with cluster nodes over Network B:

HPE Data Fabric provides two environment variables, `MAPR_SUBNETS` and `MAPR_EXTERNAL`, that you can use to segregate NICs for internal and external clients or to segregate NICs for high-performance and low-performance clients.

MAPR_SUBNETS Environment Variable

The `MAPR_SUBNETS` environment variable can be used to restrict HPE Data Fabric to a subset of NICs. If `MAPR_SUBNETS` is not set, all IPs are available for all communication. The following table describes the behavior when `MAPR_SUBNETS` is set on:

Node Type	Behavior
File System	The file system registers these IP addresses with CLDB as internal IP addresses on which file-system nodes can be reached.
CLDB	The CLDB advertises the IP address to clients on the cluster.

You can set the MAPR_SUBNETS environment variable in the `/opt/mapr/conf/env_override.sh` file on all the nodes. On the cluster nodes, the value for this environment variable is a comma-separated list of subnet masks. For example:

```
export MAPR_SUBNETS=10.10.15.0/24,10.10.16.0/24
```

You can specify up to four NICs in the MAPR_SUBNETS environment variable. If your system has more than four NICs, HPE Data Fabric advertises the first four it finds. Or, if the MAPR_SUBNETS environment variable is set, HPE Data Fabric restricts the networks or IPs that are advertised based on the subnets specified therein.

The MAPR_SUBNETS environment variable can be set on the client if there is a NAT between the server and client. On the client, the value for this environment variable is the IP address of the client. For example:

```
export MAPR_SUBNETS=10.11.12.13/32
```

When specifying the IP address in the MAPR_SUBNETS environment variable on the client, use `/32` to specify a single IP address.

For more information about the MAPR_SUBNETS environment variable, see [Environment Variables](#) on page 3466.

MAPR_EXTERNAL Environment Variable

If all the IP addresses on the servers are public and can be accessed from an external system, the MAPR_EXTERNAL environment variable need not be set. However, if your cluster nodes have private IP addresses, to allow clients outside the cluster to reach the cluster nodes (such as when Data Fabric is installed on the cloud or Docker container), specify the public IP addresses in the MAPR_EXTERNAL environment variable.

On the cluster nodes, set this variable in the `/opt/mapr/conf/env_override.sh` file. The following table describes the behavior when MAPR_EXTERNAL is set on:

Node Type	Behavior
File System	The file system registers these IP addresses with CLDB as the IP addresses on which external clients can reach file system nodes. Communication between file system nodes on the cluster still occurs over the internal IP addresses.
CLDB	The CLDB advertises these IPs addresses to clients outside the cluster or data center.
MAST Gateway Nodes	The gateway registers these IP addresses with the CLDB as the IP addresses on which external clients can reach the MAST Gateway.

NOTE: Do not set the MAPR_EXTERNAL environment variable on client(s).

The value for this environment variable is a comma-separated list of IP addresses. You cannot specify the hostname as value. For example:

```
export MAPR_EXTERNAL="10.0.0.101,3.87.212.119"
export MAPR_SUBNETS="172.31.00/16"
```

For example, you can specify the IP addresses of the 1GbE NICs (shown in the previous illustration) as the value for this environment variable, to allow external or low-performance clients to communicate with the cluster nodes.

```
export MAPR_EXTERNAL=10.11.0.0
```

For more information about the MAPR_EXTERNAL environment variable, see [Environment Variables](#) on page 3466.

IP Addresses for ZooKeeper Nodes

You can specify the IP addresses of ZooKeeper nodes by running the [configure.sh](#) on page 3186 utility with both the -Z and -EZ options during cluster configuration. The following table summarizes how to use these options:

When using this option	You specify
-Z	Internal IP addresses
-EZ	External IP addresses

When you specify the IP addresses using the -Z and -EZ options, these IP addresses are registered with the CLDB and included in the `cldb.conf` file. In the `cldb.conf` file, the internal IP addresses set using the -Z option are the values for the `cldb.zookeeper.servers` parameter. The external IP addresses set using the -EZ option are the values for the `cldb.external.zookeeper.servers` parameter.

NOTE: You do not need to run the `configure.sh` command with the -EZ option during client configuration.

For more information, see [configure.sh](#) on page 3186.

If all the ZooKeepers have different IP addresses, port forwarding is not required and, optionally, you can specify the same port with all the IP addresses. However, in some cases, such as when a single external IP address is used by multiple ZooKeepers (as in a Docker container), you can specify ports for ZooKeepers when you run the `configure.sh` utility with the -Z and -EZ options. For more information, see [Specifying Ports](#) on page 1424.

Internal and External Clients

Clients communicating with the the CLDB using internal IP address (of CLDB) are considered internal clients (or clients within the cluster). Clients communicating with the CLDB using external IP address (of CLDB) are considered external clients (or clients outside the cluster).

To configure a client as an internal or high-performance client, include the CLDB internal IP address in the `mapr-clusters.conf` file on the client host. Similarly, to configure a client as an external or low-performance client, include the CLDB external IP address in the `mapr-clusters.conf` file on the client host.

The `mapr-clusters.conf` file on the client host should not contain both internal and external IP addresses of the server on a cluster. The `mapr-clusters.conf` file can contain internal and external IP addresses only when the entries in the file on the client host are for multiple clusters.

For example, suppose you have a client, which is an internal client on one cluster and external client on another cluster. The `mapr-clusters.conf` file on the client host can contain the CLDB internal IP address for the cluster on which the client is considered an internal client and the CLDB external IP address for the cluster on which the client is considered an external client.

NOTE: Update the environment variables for NIC segregation as specified in [Setting Environment Variables for NIC Segregation](#) on page 1422 and run `configure.sh` with the appropriate options to update the IP addresses in the `mapr-clusters.conf` file.

For more information, see [configure.sh](#) on page 3186.

The `mapr-clusters.conf` file on the cluster nodes should not contain any external IP address.

Limitations

Note the following limitations for using the environment variables:

- If both `MAPR_SUBNETS` and `MAPR_EXTERNAL` environment variables are set, the segregation of NICs for internal and external communication is possible. Internal communication happens over the IP addresses listed in the `MAPR_SUBNETS` environment variable, and external communication happens over the IP addresses listed in the `MAPR_EXTERNAL` environment variable. Do not directly change environment variable values in the `mapr-clusters.conf` file. Run the `configure.sh` script instead.
- If only the `MAPR_SUBNETS` environment variable is set, the file system registers the IP addresses in the `MAPR_SUBNETS` environment variable with the CLDB as internal IPs.

NOTE: To segregate internal or high-performance clients, and external or low-performance clients, set both the environment variables in the `/opt/mapr/conf/env_override.sh` file.

- You can specify up to four IP addresses in the `MAPR_SUBNETS` environment variable, and four IP addresses in the `MAPR_EXTERNAL` environment variable.
- You must configure ZooKeeper with an IP address that is reachable by both internal and external clients.
- Do not run any of the following clients in a Docker image on a host server with multiple NICs:
 - File-system, database, or Marlin clients
 - NFS server variants
 - Applications using the `mapr-client` library

Summary

The following table describes the environment variables to set for the various services that use non-default ports and that support public IP address(es) for communication with external clients and remote clusters:

Service	Environment variable to set...	
	Public IP Address for External Clients/ Remote Clusters	Non-default Port
CLDB	MAPR_EXTERNAL	CLDB_EXTERNAL_RPC_PORT
File System	MAPR_EXTERNAL	MAPR_EXTERNAL
MAST Gateway	MAPR_EXTERNAL	MASTGATEWAY_EXTERNAL_RPC_PORT

The following illustration shows the client communicating with the CLDB, HPE Data Fabric file system, and MAST Gateway using the IP address(es) defined in the `MAPR_EXTERNAL` environment variable. This is because all the IP addresses on the servers are not public and accessible outside the cluster. All communication between CLDB, file system, and MAST Gateway on the same cluster happen over the IP

address specified in the `MAPR_SUBNETS` environment variable. This is because communication between the services and clients on the cluster is restricted to a subset of the available NICs.

When the client connects to the HPE Data Fabric file system from outside the cluster, the client uses either the default port (5660) or the port specified for the Data Fabric file system in the `MAPR_EXTERNAL` environment variable.

When communicating with the CLDB, if the `CLDB_EXTERNAL_RPC_PORT` environment variable is set, the client communicates with the CLDB over the port specified in this environment variable. Similarly for MAST Gateway, if the `MASTGATEWAY_EXTERNAL_RPC_PORT` environment variable is set, the client communicates with MAST Gateway over the port specified in this environment variable. For both CLDB and MAST Gateway, if the ports are not set in the `CLDB_EXTERNAL_RPC_PORT` and `MASTGATEWAY_EXTERNAL_RPC_PORT` environment variables respectively, the client communicates over the default port.

The following illustration shows that during mirroring and other cross-cluster activities, the services on the destination cluster communicate with the services on the source cluster using the IP address defined in the `MAPR_EXTERNAL` environment variable. As with the external client, the services and clients in the remote destination cluster communicate with the services in the source cluster over the default ports or the port specified in the environment variable for the service.

Setting Environment Variables for NIC Segregation

Describes how to set environment variables to segregate NICs.

About this task

Use the `MAPR_SUBNETS` and `MAPR_EXTERNAL` environment variables to segregate NICs for internal and external clients, or to segregate NICs for high-performance and low-performance clients.

Setting the `MAPR_SUBNETS` Environment Variable

About this task

To specify the internal IP addresses of CLDB and file system nodes:

Procedure

1. Stop warden on all the nodes on the cluster.
2. Set the IP address range to use in the `MAPR_SUBNETS` environment variable in the `/opt/mapr/conf/env_override.sh` file. For more information about this file, see [About `env\_override.sh`](#) on page 3467.

For example:

```
export MAPR_SUBNETS=10.10.0.0/24
```

To specify multiple subnets for HPE Data Fabric, use comma to separate the IP addresses.

Before specifying the IP address, make sure the client and cluster nodes can communicate using that IP address. That is, ensure that the client can send packets and that they can be routed to all the interfaces of the cluster nodes, and the cluster nodes all have a route that reaches back to the client IP address.

NOTE: For standalone programs (not using the `mapr` classpath), which do not pick up the settings in the `/opt/mapr/conf/env.sh` file, set `MAPR_SUBNETS` explicitly before the start of program.

3. Perform a rolling restart of warden on all the nodes for the changes to take effect.
4. Add CLDB's internal IP address (or IP address specified in the MAPR_SUBNETS environment variable on the CLDB host) to the `mapr-clusters.conf` file on the (internal or high-performance) client host(s).

The `mapr-clusters.conf` file specifies IP addresses, on which the CLDB nodes (for one or more clusters) can be reached. For more information, see [mapr-clusters.conf](#) on page 3370.

Results

When you restrict HPE Data Fabric to certain subnets, HPE Data Fabric clients have full access to the HPE Data Fabric cluster on the designated subnets.

Setting the MAPR_EXTERNAL Environment Variable

About this task

To specify the external IP addresses of CLDB, file system, and/or MAST Gateway nodes:

Procedure

1. Stop warden on all the nodes on the cluster.
2. Set the IP addresses to use for external communication or for low-performance clients in the MAPR_EXTERNAL environment variable in the `/opt/mapr/conf/env_override.sh` file. For more information about this file, see [About env_override.sh](#) on page 3467.

For example:

```
export MAPR_EXTERNAL=10.11.0.0;
```

To specify multiple subnets for HPE Data Fabric, use a comma to separate the IP addresses.

3. Perform a rolling restart of warden on all the nodes for the changes to take effect.
4. Add the following in the [mapr-clusters.conf](#) file on the (external or low-performance) client host(s):
 - CLDB's external IP addresses, which is the IP addresses specified in the MAPR_EXTERNAL environment variable on the CLDB hosts.
 - CLDB's external port, which is the value of the CLDB_EXTERNAL_RPC_PORT environment variable if this is set on the CLDB hosts. See [Specifying Ports for CLDB](#) for more information.

The [mapr-clusters.conf](#) file contains the IP addresses, on which the CLDB nodes (for one or more clusters) can be reached. For more information, see [mapr-clusters.conf](#) on page 3370.

Examples

Suppose the value for the MAPR_EXTERNAL environment variable on file system node is the following:

```
10.10.103.80,10.10.30.205
```

External clients can connect to file system on IPs 10.10.103.80, 10.10.30.205 and the ports on which the file system is reachable are the default ports. If file system is running 2 instances, then:

- Instance 1 is reachable on 10.10.103.80:<5660>, 10.10.30.205:<5660>
- Instance 2 is reachable on 10.10.103.80:<5661>, 10.10.30.205:<5661>

If file system is running 3 instances:

- Instance 1 is reachable on 10.10.103.80:<5660>, 10.10.30.205:<5660>
- Instance 2 is reachable on 10.10.103.80:<5661>, 10.10.30.205:<5661>
- Instance 3 is reachable on 10.10.103.80:<5662>, 10.10.30.205:<5662>

Suppose the value for the MAPR_EXTERNAL environment variable on a MAST Gateway node is the following:

```
10.20.30.100
```

External clients can connect to MAST Gateway on IP 10.20.30.100 and the port on which MAST Gateway is reachable is the default port (8660). If file system is also running on this node, then both file system and MAST Gateway are reachable on the IP 10.20.30.100 and the ports on which they are reachable are the default ports.

Specifying External IP Address of ZooKeeper Nodes

About this task

To specify the external IP addresses of ZooKeeper nodes, during cluster configuration:

Procedure

- Run the [configure.sh](#) utility as follows:

```
/opt/mapr/server/configure.sh -C <hostname|IP>[,<hostname|IP>, ..] -Z
<IP>[,<IP>..] \
-EZ <IP>[:<port>][,<IP>[:<port>]..] [-F <disk_list_file>] [-N
<cluster_name>]
```

In the preceding command:

- When each ZooKeeper node has a different external IP address, use the -EZ option to specify the IP address of each ZooKeeper node, and optionally the port as well (separated by a colon); the IP address can be different while the port number must be the same for every node.
- When there are multiple ZooKeeper nodes listening on the same external IP (such as in a Docker container), use the -EZ option to specify IP address and port (separated by a colon); the port can be different while the IP address is the same for every node.

For more information, see [Specifying Ports](#) on page 1424.

Specifying Ports

About this task

On installations where the file system instances, CLDB, and/or MAST Gateway must be reached on non-standard ports, you can specify the ports to advertise in the MAPR_EXTERNAL, CLDB_EXTERNAL_RPC_PORT, and MASTGATEWAY_EXTERNAL_RPC_PORT environment variables respectively. This setting does not change the ports used by the servers, but changes the ports advertised to clients (to support port forwarding).

If the cluster nodes are no longer reachable on the standard ports, you can specify ports for file system using the MAPR_EXTERNAL environment variable. MAPR_EXTERNAL allows the specification of the advertised ports for the file system instances only; this environment variable cannot be used to specify ports for CLDB or the MAST Gateway. Instead, use CLDB_EXTERNAL_RPC_PORT environment variable to specify port for CLDB and MASTGATEWAY_EXTERNAL_RPC_PORT environment variable to specify port for MAST Gateway. If ZooKeeper is not available on the default port or if there are multiple

ZooKeepers listening on the same external IP address, you can specify ports for each ZooKeeper using the [configure.sh](#) utility.

See the following sections for more information on setting the ports.

Specifying Ports for file system

About this task

If the port forwarding table is set up, ports must be configured for every file system node on every file system instance. For more information on the number of ports used by file system instance(s), see [Ports Used by HPE Data Fabric Software](#) on page 3469. To specify the ports for file system:

Procedure

1. Open the \$MAPR_HOME/conf/env_override.sh file. If the env_override.sh file is not present, you might have to create it. See [About env_override.sh](#) on page 3467.
2. Set the value for the MAPR_EXTERNAL environment variable.
The value for the MAPR_EXTERNAL environment variable is a comma-separated list of IP addresses and colon-separated list of ports (to use for port forwarding).

For example:

```
export MAPR_EXTERNAL=10.11.0.0;9000,9001,9002,9003
```

The following example shows 3 file system instances with 4 ports:

```
export
MAPR_EXTERNAL=10.11.0.0;9000,9001,9002,9003:10000,10001,10002,10003:11000
,11001,11002,11003
```

To specify:

- Multiple IP addresses, use comma to separate the IP addresses.
- Ports for multiple instances, use:
 - comma (,) to separate the ports for an instance
 - colon (:) to separate the set of ports for each instance

If ports are not specified, file system is assumed to be reachable on the default ports.

3. Save and close the \$MAPR_HOME/conf/env_override.sh file.

Specifying Ports for CLDB

About this task

The default port for CLDB is 7222. If you want to use another port:

Procedure

1. Open the \$MAPR_HOME/conf/env_override.sh file on the CLDB host(s). If the [env_override.sh](#) file is not present, you might have to create it. See [About env_override.sh](#) on page 3467.

2. Set the value for the `CLDB_EXTERNAL_RPC_PORT` environment variable in the file.

The value for this environment variable is the port to use for CLDB.

For example:

```
export CLDB_EXTERNAL_RPC_PORT=5000
```

This is especially useful if HPE Data Fabric is installed in a Docker container or other guest hosts. If this is not set, CLDB must be reachable on the default port 7222.

3. Save and close the `$MAPR_HOME/conf/env_override.sh` file.
4. Ensure that the [mapr-clusters.conf](#) file on the client host(s) contains the correct port number for CLDB.

What to do next

NOTE: After setting this environment variable, make sure that `cldb.feature.external.ip` is enabled if you upgraded from a prior version of MapR to v6.0. For more information on enabling this feature, see [Step 4: Enable New Features](#) on page 492.

Specifying Port for MAST Gateway

About this task

The default port for MAST Gateway is 8660. If you want to use another port:

Procedure

1. Open the `$MAPR_HOME/conf/env_override.sh` file on the MAST Gateway host(s). If the [env_override.sh](#) file is not present, you might have to create it. See [About env_override.sh](#) on page 3467.
2. Set the value for the `MASTGATEWAY_EXTERNAL_RPC_PORT` environment variable in the file.
The value for this environment variable is the port to use for MAST Gateway.

For example:

```
export MASTGATEWAY_EXTERNAL_RPC_PORT=15000
```

If this is not set, MAST Gateway must be reachable on the default port 8660.

3. Save and close the `$MAPR_HOME/conf/env_override.sh` file.

Specifying Ports for ZooKeeper

About this task

If ZooKeeper is not available on the default port or if all the ZooKeepers are listening on the same external IP address (such as in a Docker container), you can specify the port on which to reach each ZooKeeper. To specify the port on which to reach each ZooKeeper, during cluster configuration:

Procedure

- Run the [configure.sh](#) utility with the `-EZ` option.

The value for the `-EZ` option is a comma-separated list of external IP addresses of the ZooKeeper nodes and the port (for each IP address), separated by a colon, on which ZooKeeper can be reached. For example:

```
/opt/mapr/server/configure.sh -C <IP|Hostname>[,<IP|Hostname>, ...] -Z <IP|
Hostname>[,<IP|Hostname>, ...] \
-EZ <IP|Hostname>:<Port>[,<IP|Hostname>:<Port>, ...]
```

For example, you can specify:

- Different ports when the same external IP address is used for all ZooKeeper nodes as shown below:

```
/opt/mapr/server/configure.sh -C 172.17.0.2,172.17.0.3,172.17.0.4 -Z
172.17.0.2,172.17.0.3,172.17.0.4 \
-EZ 10.10.104.34:5181,10.10.104.34:5182,10.10.104.34:5183 -N
my.cluster.com
```

- Same ports when different IP addresses are specified for ZooKeeper nodes:

```
/opt/mapr/server/configure.sh -C 172.17.0.2,172.17.0.3,172.17.0.4 -Z
172.17.0.2,172.17.0.3,172.17.0.4 \
-EZ 10.10.104.34:5181,10.20.105.34:5181,10.30.106.34:5181 -N
my.cluster.com
```

Configuring MR AppMaster Port Mapping

Procedure

1. Set the `yarn.app.mapreduce.am.job.client.port-range` parameter in the [yarn-site.xml](#) file to specific range of free ports in all the NodeManager nodes.

Specify the range of ports that the MapReduce AppMaster can use when binding. Do not specify a value for this parameter if you want all possible ports. For example:

```
50000-50050,50100-50200
```

NOTE: Each Docker instance where NodeManager is running should have different range and the range should be different across all NodeManager nodes.

For example:

The `yarn-site.xml` file in docker container 1:

```
<property>
  <name>yarn.app.mapreduce.am.job.client.port-range</name>
  <value>50000-50050</value>
</property>
```

The `yarn-site.xml` file in docker container 2:

```
<property>
  <name>yarn.app.mapreduce.am.job.client.port-range</name>
  <value>50100-50150</value>
</property>
```

The `yarn-site.xml` file in docker container 3:

```
<property>
  <name>yarn.app.mapreduce.am.job.client.port-range</name>
  <value>50151-50200,50250-50300</value>
</property>
```

2. Set the port forwarding rules in host machine for these specific ranges.
For example, if NM1 contains ranges from 50000 to 50050, then set the IP table rules such that when requests come on these ports, it is forwarded to NM1.
3. Specify the AWS or Docker host name for the IP address in the `/etc/hosts` file on the client system so that external clients can resolve Docker or AWS hostname properly when running the jobs.
For example, your entry in the `/etc/hosts` file should look similar to the following:

```
54.208.145.112 ip-10-10-0-103.ec2.internal
```

Working with a Logical Volume Manager

Explains the role and usage of a Logical Volume Manager.

The Logical Volume Manager creates symbolic links to each logical volume's block device, from a directory path in the form:

```
/dev/<volume group>/<volume name>
```

HPE Data Fabric needs the actual block location, which you can find by using the `ls -l` command to list the symbolic links.

1. Make sure you have free, unmounted logical volumes for use by HPE Data Fabric:
 - Unmount any mounted logical volumes that can be erased and used for HPE Data Fabric.
 - Allocate any free space in an existing logical volume group to new logical volumes.
2. Make a note of the volume group and volume name of each logical volume.
3. Use `ls -l` with the volume group and volume name to determine the path of each logical volume's block device. Each logical volume is a symbolic link to a logical block device from a directory path that uses the volume group and volume name:

```
/dev/<volume group>/<volume name>
```

The following example shows output that represents a volume group named `mapr` containing logical volumes named `mapr1`, `mapr2`, `mapr3`, and `mapr4`:

```
ls -l /dev/mapr/mapr*
lrwxrwxrwx 1 root root 22 Apr 12 21:48 /dev/mapr/mapr1 -> /dev/mapper/
mapr-mapr1
lrwxrwxrwx 1 root root 22 Apr 12 21:48 /dev/mapr/mapr2 -> /dev/mapper/
mapr-mapr2
lrwxrwxrwx 1 root root 22 Apr 12 21:48 /dev/mapr/mapr3 -> /dev/mapper/
mapr-mapr3
lrwxrwxrwx 1 root root 22 Apr 12 21:48 /dev/mapr/mapr4 -> /dev/mapper/
mapr-mapr4
```

4. Create a text file `/tmp/disks.txt` containing the paths to the block devices for the logical volumes (one path on each line). Example:

```
cat /tmp/disks.txt
/dev/mapper/mapr-mapr1
/dev/mapper/mapr-mapr2
/dev/mapper/mapr-mapr3
/dev/mapper/mapr-mapr4
```

5. Pass `disks.txt` to [disksetup](#).

Tuning for SSDs

Lists the parameters to tune for optimal SSD performance.

About this task

On servers with SSDs:

Procedure

1. Enable TRIM operation in the `mfs.conf` file, if recommended by the SSD vendor.
By default, TRIM is disabled. To enable, set the value for `mfs.ssd.trim.enabled` to 1 in the `mfs.conf` file. For example:

```
mfs.ssd.trim.enabled=1
```

2. Disable IO throttling in the `mfs.conf` file.
To disable, set the value for `mfs.disk.iothrottle.count` to 50000. The default value for `mfs.disk.iothrottle.count` is 100. For example:

```
mfs.disk.iothrottle.count=50000
```

3. Create storage pool with multiple SSDs (so that the throughput is less than 2GB/sec).

NOTE: Create one storage pool per SSD only if the device is high-end.

To create, run `disksetup`:

```
/opt/mapr/server/disksetup -W <n> disks.txt
```

For example, to create a storage pool with 2 SSDs, run the following command:

```
/opt/mapr/server/disksetup -W 2 disks.txt
```

For more information, see [disksetup](#) on page 3230.

Administering Volumes

This section provide information about how to organize and manage data using volumes, a unique feature of HPE Data Fabric clusters.

HPE Data Fabric provides volumes as a way to organize data and manage cluster performance. A volume is a logical unit that allows you to apply policies to a set of files, directories, and sub-volumes. You can use volumes to enforce disk usage limits, set replication levels, establish ownership and accountability, and measure the cost generated by different projects or departments. Create a volume for each user, department, or project.

You can mount volumes under other volumes to build a structure that reflects the needs of your organization. Sub-volumes are created by mounting a volume in a sub-directory of an already mounted volume. This establishes a parent-child relationship between the volumes whereas the parent volume is mounted in top-level directory and the child volume is mounted in the sub-directory. The volume structure defines how data is distributed across the nodes in your cluster. Create multiple small volumes with shallow paths at the top of your cluster's volume hierarchy to spread the load of access requests across the nodes.

A well-structured volume hierarchy is an essential aspect of your cluster's performance. As your cluster grows, keeping your volume hierarchy efficient maximizes data availability. Cluster performance is negatively affected when a volume structure is not in place.

The Control System **Volumes** page under **Data** contains the following tabs:

- [Summary](#)
- [Snapshots](#)
- [User Disk Usage](#)
- [Schedules](#)
- [Storage Policies](#)
- [Remote Targets](#)

Managing Data with Volumes

Provides an overview of how to manage volume data.

The **Summary** tab in the **Volumes** page displays the following panes:

- [Top Volume Utilization](#) — Volumes that use the most amount of disk space.
- [Active Alarms](#) — List of active volume alarms on the cluster.
- Local and Remote Tier Storage utilization.
- [Volumes](#) — List of volumes.

The page includes the **Create Volume** button to create standard or (local and/or remote) mirror volumes. You can perform the following procedures to manage volumes on the HPE Data Fabric cluster using the Control System and the CLI.

Viewing the List of Volumes

Explains how to view the list of volumes either through the Control Panel or the CLI.

Viewing All the Volumes Using the Control System

Procedure

- Log in to the Control Panel and click **Data > Volumes > Summary**.

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

The **Volumes** pane in the **Summary** tab (under **Data > Volumes**) displays the volumes in the cluster.

NOTE: By default, system volumes are not displayed. If you wish to view system volumes also, select the **Include System Volumes** checkbox.

If you are in another view, select **All Volumes** from the drop-down menu in the **Volumes** pane. Up to 10 volumes, sorted by name, are displayed in each page. For each volume, the pane displays the following information, by default:

Column Name	Column Description
Volumes	The name of the volume (used for default sorting).
Data Tiering	Whether volume is enabled or disabled for data tiering.

Column Name	Column Description
Alarms	The number of alarms associated with the volume. Hover the cursor over the number for information on the alarm including alarm name, severity, and time when the alarm was raised.
Mnt	Specifies whether (✓) volume is mounted.
Type	The type of volume. Both standard and mirror volumes are displayed.
Mount Path	The path where the volume is mounted.
Creator	The user or group that owns the volume.
Quota	The amount of disk space allocated and utilized by the volume and associated snapshots and the cluster reserve limit (in red). If quota is not set, displays option to Set Quota .
Total Size	The total physical size of the volume and associated snapshots. When you move the cursor over the value, the popover shows the total logical size (Data Size), the logical size of the volume (Volume Size), and the logical size of the snapshots (Snapshot Size).
RF	The replication factor that specifies the number of copies for the volume.
Physical Topology	The rack path to the volume.

You can sort the list by volume name, mount, mount path, or creator.

Selecting the checkbox beside a volume makes the **Actions** drop-down menu available. From the **Actions** drop-down menu, you can:

- [Edit](#) the selected volume(s)
- [Remove](#) the selected volume(s)
- [Create snapshot\(s\)](#) of the selected volume
- [Change](#) the selected mirror volume(s) to standard volume(s)
- [Start](#) the mirroring operation(s) for the selected mirror volume(s)
- [Stop](#) the mirroring operation(s) for the selected mirror volume(s)
- [Mount](#) the selected volume(s)
- [Unmount](#) the selected volume(s)
- [Offload](#) selected volume(s)
- [Recall](#) selected volume(s)
- [Abort](#) currently running tiering job for selected volume(s)

Viewing the List of Standard Volumes Using the Control System

About this task

The **Volumes** pane in the **Summary** tab under **Data > Volumes** (under **Volumes** in the Kubernetes version of the Control System) displays all the volumes in the cluster by default. To view a list of only the standard volumes:

Procedure

- Select **Standard Volumes** from the drop-down menu in the **Volumes** pane.
The list of standard volumes in the cluster displays. By default, the list is sorted by volume name. For each volume, the page displays the following information by default:

Column Name	Description
Volumes	The name of the volume (used for default sorting).
Alarms	The number of alarms associated with the volume. You can view the Active Alarms pane for more information on the alarms associated with a volume.
Mnt	Specifies whether the volume is mounted.
Type	The type of volume. Only standard volumes are displayed.
Mount Path	The path where the volume is mounted.
Data Tiering	Whether volume is enabled or disabled for data tiering.
Creator	The user or group that owns the volume.
Quota	The amount of disk space allocated and utilized by the volume and associated snapshots and the reserve limit (in red). If quota is not set, displays option to Set Quota .
Total Size	The size of the volume and associated snapshots.
RF	The replication factor that specifies the number of copies for the volume.
Physical Topology	The rack path to the volume.

Selecting the checkbox beside a volume makes the **Actions** drop-down menu available. From the **Actions** drop-down menu, you can:

- [Edit](#) the selected volume(s)
- [Remove](#) the selected volume(s)
- [Create snapshot\(s\)](#) of the selected volume
- [Mount](#) the selected volume(s)
- [Unmount](#) the selected volume(s)

Viewing the List of Mirror Volumes Using the Control System

About this task

The **Volumes** pane in the **Summary** tab under **Data > Volumes** (under **Volumes** in the Kubernetes version of the Control System) displays the list of (both) standard and mirror volumes in the cluster by default. To view a list of only the mirror volumes:

Procedure

- Select **Mirror Volumes** from the drop-down menu in the **Volumes** pane.

The list of mirror volumes in the cluster displays. By default, the list is sorted by volume name and the following columns are displayed:

Column Name	Description
Volumes	The name of the volume (used for default sorting).
Alarms	The number of alarms associated with the volume. You can view the Active Alarms pane (above) for more information on the alarms associated with a volume.
Mnt	Specifies whether the volume is mounted.
Source Volume	The source volume name for the mirror volume.
Source Cluster	The source cluster name for the mirror volume.
Originating Cluster	The originating cluster for the data being mirrored.
Originating Volume	The originating volume for the data being mirrored.
Mirror Status	The status of the last mirroring operation.
Percentage Complete	The percentage of the in-progress mirroring operation that has been completed.
Data Tiering	Whether or not the volume is enabled or disabled for data tiering.

Selecting the checkbox beside a volume makes the **Actions** drop-down menu available. From the **Actions** drop-down menu, you can:

- [Edit](#) the selected volume(s)
- [Remove](#) the selected volume(s)
- [Create snapshot\(s\)](#) of the selected volume
- [Change](#) the mirror volume to a standard volume
- [Start](#) the mirroring operation(s) for the selected mirror volume(s)
- [Stop](#) the mirroring operation(s) for the selected mirror volume(s)
- [Mount](#) the selected volume(s)
- [Unmount](#) the selected volume(s)

Viewing the List of Tiered Volumes Using the Control System

About this task

The **Volumes** pane in the **Summary** tab of the **Data > Volumes** page (under **Volumes** in the Kubernetes version of the Control System) displays the list of (both) standard and mirror volumes in the cluster by default. To view a list of tiered standard and mirror volumes:

Procedure

- Select **Tiered Volumes** from the drop-down menu in the **Volumes** pane.

The list of tiered standard and mirror volumes in the cluster displays. By default, the list is sorted by volume name. For each volume, the pane displays the following information, by default:

Column Name	Description
Volumes	The name of the volume (used for default sorting).
Offload Tier	The name of the tier where the volume data is stored.
Job	<p>The tiering operation that is currently running or was last performed on the volume. Value can be one of the following:</p> <ul style="list-style-type: none"> • Offload — if volume data was offloaded or is currently being offloaded • Abort — if volume data offload or recall operation was aborted or is being aborted • Recall — if volume data was recalled or is being recalled from the tier
State	The status of the job.
Progress	The job completion percentage.
Start Date/Time	The date and time when the job was started.
End Date/Time	The date and time when the job completed.
Offload Speed	The amount of data (in MB) offloaded or being offloaded per second.
Recall Speed	The amount of data (in MB) recalled or being recalled per second.

Selecting the checkbox beside a volume makes the **Actions** drop-down menu available. From the **Actions** drop-down menu, you can:

- [Edit](#) selected volume(s)
- [Remove](#) selected volume(s)
- [Create snapshot\(s\)](#) of selected volume(s)
- [Change](#) the mirror volume to a standard volume
- [Start](#) the mirroring operation(s) for the selected mirror volume(s)
- [Stop](#) the mirroring operation(s) for the selected mirror volume(s)
- [Mount](#) selected volume(s), if they are not already mounted
- [Unmount](#) selected volume(s), if they are currently mounted
- [Offload](#) selected volume(s)
- [Recall](#) selected volume(s)
- [Abort](#) currently running tiering job for selected volume(s)

Retrieving the List of Volumes Using the CLI and REST API

About this task

The basic command to retrieve the list of volumes is:

```
maprcli volume list
```

For complete reference information, see [volume list](#) on page 2989.

Customizing the List of Columns/Fields

Explains how to customize the columns that are displayed in the Control System, and the fields that are returned in the CLI.

Customizing the Columns in the Control System

Procedure

- Log in to the Control System and go to:
 - Data > Volumes** page to customize columns displayed in the **Volumes** pane.
 NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.
 - Nodes** page to customize columns displayed in the **Nodes** pane.
 NOTE: The **Nodes** page is not available on the Kubernetes version of the Control Panel.
- Click the **Customize Columns** icon ().
In the **Customize Columns** dialog, the:
 - Available** list displays the columns that are available for display.
 - Selected** list displays the columns currently displayed in the pane.
- Select the columns from the:
 - Available list of columns and click  to move selection to **Selected** columns (for display).
 - Selected list of columns and click  to remove selected columns from displaying.
- (Optional) Click  and/or down  arrows to sort the order of columns.
- Click **Save Changes** for the customization to take effect.

TIP: To reset the display to its default columns, click **Reset to default columns**.

Customizing the Fields Using the CLI or REST API

About this task

Use the `-column` parameter with the `maprcli` command to view specific fields in the list. For example:

- To view the health of the nodes and services installed on the nodes being retrieved, run the following command:

```
maprcli node list -columns service,health
```

For complete reference information, see the [node list](#) on page 2570 command.

- To view the volume name for the list of volumes being retrieved, run the following command:

```
maprcli volume list -columns volumename
```

For complete reference information, see [volume list](#) on page 2989 command.

Reverting to Default List of Columns

Describes how to revert to the default list of columns on the Control System

Procedure

1. Log in to the Control System and click:

- **Data > Volumes** to revert to the default list of columns in the **Volumes** pane.

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

- **Nodes** to revert to the default list of columns in the **Nodes** pane.

NOTE: The **Nodes** page is not available in the Kubernetes version of the Control System.

2. Click the **Customize Columns** icon (⚙️).

3. Click **Reset to default columns**,

4. Click **Save Changes**.

The pane displays the default list of columns.

Filtering the List of Volumes

Explains how to filter the list of volumes using either the Control System or the CLI.

About this task

The filter lets you build search expressions to provide sophisticated filtering capabilities for locating specific data on views that display a large number of volumes. Expressions are implicitly connected by the AND operator.

Filtering on the Control System

Procedure

1. Log in to the Control System and click **Data > Volumes** to filter volumes in the **Volumes** pane.

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Select one of the following options from the **Add Filter** drop-down menu:

- Volume — to filter the list by volume name
- Usage — to filter the list by amount of disk used
- Mount Path — to filter the list by mount path
- Creator — to filter the list by entity or volume owner
- Total Size — to filter the list by size of volume

- Replication Factor — to filter the list by replication factor
 - Physical Topology — to filter by the rack path
 - Tier Type - to filter by a type of tier
 - Quota — to filter by hard quota
 - Data on Wire Encryption — to filter by volumes enabled (**On**) or disabled (**Off**) for on-wire encryption
 - Data at Rest Encryption — to filter by volumes enabled (**On**) or disabled (**Off**) for data-at-rest encryption (DARE)
 - Last Access Time - to filter by the [Last Access Time](#)
 - Coalesce Interval - to filter on the [coalesce interval](#)
3. Specify the value in the drop-down field for the selected filter (by which to filter the list of volumes) and click **Filter**.
- As you make selections and specify the filtering criteria, the pane displays only the volumes that match the specified filtering criteria.
4. Click:
- **Add Filter** to add another filtering criteria.
 -  to remove a filtering criteria.
 -  to clear all filter settings.

Filtering Using the CLI

About this task

The [volume list](#) on page 2989 command can be used with the `-filter` option, which let you specify large numbers of volumes by matching specified values in specified fields rather than by typing each name explicitly. For example, you can display all volumes whose owner is `root` and whose name begins with `test` as follows:

```
maprcli volume list -filter [n=="test*"]and[on=="root"]
```

For more information, see [Filters](#) on page 2270.

Creating a Volume

Describes how to create a volume using the Control System, CLI and the REST API.

About this task

You can create a new (Standard or Mirror) volume using the Control System, the CLI, and the REST API.

Creating a Volume Using the Control System

About this task

To create a new (Standard or Mirror) volume using the Control System:

Procedure

1. Go to the **Data > Volumes** page and click **Create Volume** to display the **Create New Volume** page.

NOTE: When running on a Kubernetes cluster, the **Create Volume** option is on the **Volumes** page.

2. Choose the **Volume Type** in the **Properties** section. Choose:
 - **Standard Volume** to create a read-write volume.
 - **Mirror Volume** to create a volume that is a read-only copy of an existing volume.

TIP: See also: [Mirror Types](#) on page 570.

3. Specify the following required settings in the **Properties** section:

Standard Volume

Volume Name	<p>Enter a name for the volume.</p> <p>The name should contain only the following characters:</p> <div>A-Z a-z 0-9 _ - .</div> <p> NOTE:</p> <ul style="list-style-type: none">• The volume name should not begin with mapr . because mapr . is used for system volumes. If you use mapr . at the start of the volume name, the volume may not display in the default view of the list of volumes in the Control System; you must select the Include System Volumes checkbox in the Volumes pane to view volumes with names beginning with mapr .• For tiering-enabled volumes, volume name should not exceed ninety-eight characters.
Accountable Entity	<p>Specifies a user or group whose use of a volume can be subject to quotas. You can set or modify quotas that limit the space used by all the volumes owned by an accountable entity.</p>

Mirror Volume

Volume Name	<div>Enter a name for the volume.</div> <div>The name should contain only the following characters:</div> <div>A-Z a-z 0-9 _ - .</div> <div><div> NOTE:</div><div><ul style="list-style-type: none">The volume name should not begin with mapr . because mapr . is used for system volumes. If you use mapr . at the start of the volume name, the volume may not display in the default view of the list of volumes in the Control System; you must select the Include System Volumes checkbox in the Volumes pane to view volumes with names beginning with mapr .For tiering-enabled volumes, volume name should not exceed ninety-eight characters.</div></div>
-------------	--

Source Cluster Name	<p>Enter the name of the cluster on which the source volume exists.</p> <p>The name should contain only the following characters:</p> <div>A-Z a-z 0-9 _ - .</div> <p>Mirroring only works between two secure clusters or between two non-secure clusters. Mirroring does not work when one cluster is secure and the other is non-secure.</p> <div> NOTE: When setting up mirror volumes for mirroring between clusters, for the mirroring operation to run successfully, servers in one cluster cannot use the same IP addresses as servers in the other cluster. For example, if node A in cluster A has a private IP address of 10.10.20.29, no server in cluster B can have the same private IP address. Also, all the servers in destination cluster must be able to reach all the servers in the source cluster and vice versa. For example, suppose 10.10.20.29 is the only IP address used by node A in cluster A; then all servers in cluster B should be able to reach the IP address 10.10.20.29.</div>
---------------------	---

Source Volume Name	<p>Enter the name of the source volume, from which the mirror volume pulls data (after selecting the source volume cluster).</p> <p>The name should contain only the following characters:</p> <div style="border: 1px solid #ccc; padding: 5px; margin: 10px 0;"> A-Z a-z 0-9 _ - . </div> <p>If the source volume is on:</p> <ul style="list-style-type: none"> • Same cluster, you create a local mirror volume, which is useful for load balancing or for providing a read-only copy of a data set. See Local Mirroring on page 571 for more information. • Another cluster, you create a remote mirror volume, which is useful for offsite backup, for data transfer to remote facilities, and for load and latency balancing. See Creating Remote Mirrors on page 1450 for more information. <div style="margin-top: 20px;">  NOTE: If you plan to enable tiering for the mirror volume, ensure that the selected source volume is also tiering-enabled. You cannot create tiering-enabled mirror volumes to mirror data in standard volumes that are not tiering-enabled. </div> <p>For information on setting up mirror cascades, see Mirror Cascades on page 572.</p>
---------------------------	---

Accountable Entity	Specifies a user or group whose use of a volume can be subject to quotas. You can set or modify quotas that limit the space used by all the volumes owned by an accountable entity.
---------------------------	---

Steps 4 to 10 are optional and allow you to define optional volume properties and optional settings for auditing, replication, data tiering, volume access, and volume administration. If you do not define these settings, default values, where available, are used. You can skip to:

- (Optional) Step 9 to associate a snapshot schedule and/or an offload schedule with the volume.
- Step 11 to create the volume with basic settings.

4. (Optional) Specify the following general settings under **Properties**:

Mount	Specifies whether to automatically mount (Yes) or not mount (No) the volume after creation. By default, volumes are mounted immediately after creation. If this is set to Yes , you must also specify the mount path.
Mount Path	The path to mount the volume. This is required if the value for Mount is Yes .  NOTE: The path must be relative to / and cannot be in the form of a global namespace path (for example, /mapr/<cluster-name>/).
Collect Metrics	Specifies whether (Yes) or not (No) to enable metrics collection for this volume. For more information, see Collecting Volume Metrics on page 1938 and Enabling Volume Metric Collection on page 1939.
Volume Access	Specifies whether the volume is read-only or a read/write volume. By default, a standard volume is created with read/write access. A mirror volume can only be a read-only volume.
Last Access Interval	Denotes the frequency at which the access time of a file is updated. See Tuning Last Access Time on page 599 for more information.

5. (Optional) Specify the following settings for data replication under **Replication and Storage** section:

Replication

Topology	Specifies the rack path to the volume. The default topology is / data.
-----------------	--

Optimize Replication for	<p>Specifies the basis for the replication factor:</p> <ul style="list-style-type: none"> High throughput, or cascading replication, where volumes are replicated sequentially on intermediate and tail containers. Low latency, or star replication, where volumes are replicated on multiple containers in parallel. <p>The default value is high throughput. See Selecting a Replication Type for High Availability on page 1485.</p>
Guarantee Min Replication	<p>Specifies whether (Yes) or not (No) to enforce minimum number of copies. If this is enabled (Yes), writes succeed only when the minimum number of copies exist. If this is enabled (Yes) and minimum number of copies are not available, the client is asked to retry.</p> <p>For more information, see Understanding Replication on page 560.</p>
Replication	<p>Specifies the minimum (Minimum Replication) and desired (Target Replication) number of copies of the volume data. The default minimum is 2, and the default target is 3.</p>
Name Container Replication	<p>Specifies the minimum (Minimum Replication) and desired (Target Replication) number of copies of the name container associated with the volume. The default minimum is 2, and the default target is 3.</p>

Storage

Data Tiering — Specifies whether to enable (**Yes**) or disable (**No**) data tiering for volume data.

By default, data tiering is enabled and volume data is stored in the hot tier (HPE Data Fabric cluster).

If you choose to enable data tiering for the volume, you can associate a tier type with the volume either now, or later by editing the volume. If you decide to associate a type of tier with the volume, proceed to the next step; otherwise, proceed to step 7.

6. (Optional) Associate a type of tier with the volume by selecting a tiering type from the **Tiering Type** drop-down list and specifying the following settings for the tier:

Erasure Coding (Warm)

For offloading data to an erasure coded volume, specify values for the following properties. If values are not specified, default values are applied.

Topology	The topology of the erasure coded volume from the drop-down list.
Storage Policy	<div>The rule for offloading data in this volume. You can click:</div> <div><ul style="list-style-type: none">Browse to select an existing rule.Create to create a new rule for offloading data. See steps 3 - 5 in the Creating a Storage Tier Policy on page 1564 topic for more information.</div> <div>If you do not select a storage policy, the default policy named <code>default.ectier.rule</code>, which is all files (p), is associated with the volume.</div>

Scheme	<p>The erasure coding scheme, which is the number of data chunks and number of parity chunks. Set the required Parity Scheme. The system indicates in real-time whether or not the parity scheme is valid. Some valid parity schemes include:</p> <ul style="list-style-type: none"> • 3+2 — for 3 data chunks and 2 parity chunks. You must have 5 or more nodes on the cluster for this option. If selected, this scheme has 60% storage overhead and can tolerate failure of up to 2 nodes. • 4+2 — for 4 data chunks and 2 parity chunks. You must have 6 or more nodes on the cluster for this option. If selected, this scheme has 50% storage overhead and can tolerate failure of up to 2 nodes. • 5+2 — for 5 data chunks and 2 parity chunks. You must have 7 or more nodes on the cluster for this option. If selected, this scheme has 40% storage overhead and can tolerate failure of up to 2 nodes. • 6+3 — for 6 data chunks and 3 parity chunks. You must have 9 or more nodes on the cluster for this option. If selected, this scheme has 50% storage overhead and can tolerate failure of up to 3 nodes. <p>To use local parity, set the Local Parity slider to Yes. The system then displays a third slider to set the number of local parity blocks.</p> <p>As you set the parity scheme, irrespective of</p>
--------	---

Remote Archiving (Cold)

For offloading data to a low cost storage alternative on the cloud, specify values for the following properties.

Storage Policy	<p>The rule for offloading data in this volume. You can click:</p> <ul style="list-style-type: none"> • Browse to select an existing rule. • Create to create a new rule for offloading data. See Creating a Storage Tier Policy on page 1564 for more information.
Remote Target	<p>The location to which the data is offloaded. You can click:</p> <ul style="list-style-type: none"> • Browse to select an existing tier. • Create to create a new tier. See Creating a Storage Tier on page 1548 for more information.
Retention Duration after Recall	<p>The number of days to retain data recalled from the tier to the HPE Data Fabric cluster. Once the number of days is reached, recalled data on the HPE Data Fabric cluster is purged (if there are no changes), or offloaded (if there are changes).</p>
Tier Encryption	<p>Specifies whether (Yes) or not (No) to enable encryption of data on the tier. This cannot be modified once it is set. The default value is No (disabled).</p>

7. (Optional) To use Label-Based Storage, enter the label and the namespace label . See [Using Storage Labels](#) on page 1575 for more information.
8. (Optional) Configure security for volume data by setting values for the properties in the **Security** section.
 - a) Enter the name of the security policy in the **SECURITY POLICIES** field to search for the security policy to associate with the volume.
 - b) Enable (**Yes**) or disable (**No**) the following audit and encryption settings by selecting the desired option:

Auditing	<p>Auditing of operations. You can either audit particular files or directories (By File or Directory) or audit all files and directories on the volume (All Volume Content). In either case, you can do the following:</p> <ul style="list-style-type: none"> Choose either Default or Custom to specify the list of directory, file, table, and streams operations to audit. <p> NOTE: Enabling <code>setattr</code> automatically enables <code>chown</code>, <code>chgrp</code>, and <code>chperm</code>. If you exclude <code>setattr</code>, these operations are automatically disabled. If you do nothing with <code>setattr</code> (neither enable nor disable), you can enable or disable <code>chown</code>, <code>chgrp</code>, and <code>chperm</code> in any combination.</p> <ul style="list-style-type: none"> Specify a Coalesce Interval, which is the interval of time during which READ, WRITE, or GETATTR operations on one file from one IP address or UID are logged only once for a particular operation, if auditing is enabled.. The default value is 60 minutes.
Data on Wire Encryption	Encryption of data in the volume during transmission. By default, this is enabled (Yes) for all new volumes in secure cluster. This is not supported on insecure clusters.
Data at Rest Encryption	Encryption of data at rest. This should be enabled only if the feature is enabled at the cluster-level. By default, this is disabled (No). This is not supported on insecure clusters.
Coalesce Interval	The interval of time (in minutes) to use when logging multiple READ, WRITE, or GETATTR operations on one file from one client IP address, if auditing is enabled. The default value is 60 minutes.

9. (Optional) Specify the users, groups, and/or roles that have and/or do not have permissions to read and/or write in the **Data Access Control** section:
 - a) Click **Add Data Access Control** to display the **Add Access Permissions** window.
 - b) Move the slider associated with **Public** to **Yes** to grant access to all or to **No** to specify a list of users, groups, and or roles and do one of the following:
 - Enter the users, groups, and/or roles in the respective text boxes.
 - Select the **Custom ACE** checkbox to enter the custom [ACE](#).
 - c) Click **Add** to select permissions for the specified users, groups, and/or roles.
 - d) Select the **Read** and/or **Write** checkbox in the **Permissions** column to grant that type of access to all (Public) or the specified users, groups, and/or roles.

Click:

-  to modify the users, groups, and/or roles.
- Add Another** to grant permissions for other users, groups, and/or roles and repeat steps b and c.
-  to create a copy of the permissions, which you can then modify.
-  to remove a data access control setting.

10. (Optional) Specify the users and groups that have volume administration permissions:

- a) Select the type of entity, user or group, and enter entity name in the **Entities** field.
- b) Select the checkbox associated with any of the following permissions to grant the user or group that type of administration control:

Dump & Backup	Transport large amount of data or copies of the volume on physical media to a remote cluster using backup files.
Restore & Mirror	Restore a volume from a dump file and create mirror volumes, which is a read-only copy of the source volume.
Edit	Edit volume properties, create and delete snapshots.
Delete	Delete the volume.
Admin (Access Control)	View and edit access control settings (but cannot perform volume operations).
Full Control	Perform all volume-related administrative operations except changing access control settings.

To define administrative access control settings for another user or group, click **Add Another** and repeat steps a and b.

NOTE: To perform this action from the command line, refer to [acl set](#) on page 2276.

By default, the root user and the volume creator have full control permissions on the volume.

- 11.** Set read (**R**), write (**W**), and/or execute (**X**) permissions on the root directory for users, groups, and others by selecting the permission.

- 12.** Click **Create Volume** to create the volume.

Creating a Volume Using the CLI and REST API

About this task

CLI

The basic command to create a (Standard) volume is:

```
/opt/mapr/bin/maprccli volume
create -name <volName> -path
<mountPath>
```

The name should contain only the following characters:

```
A-Z a-z 0-9 _ - .
```

If you are creating a:

- Mirror volume, you must specify `-type mirror` and `-source <sourceVolName>@<cluster>` in the command.
- Tiering-enabled volume, you must specify `-tieringenable true` in the command.

REST

Send a request of type POST. For example:

```
curl -X POST 'https://<hostname>:8443/
rest/volume/create?
name=<volName>&path=<mountPath>' --use
r <username>:<password>
```

The name should contain only the following characters:

```
A-Z a-z 0-9 _ - .
```

If you are creating a:

- Mirror volume, you must specify `type=mirror` and `source=<sourceVolName>@<cluster>` in the request.
- Tiering-enabled volume, you must specify `tieringenable=true` in the request. The `tieringenable` property of a mirror volume should be the same as the source volume.

For the complete list of parameters, see [volume create](#) on page 2929.

Creating Remote Mirrors

Describes the use of remote mirror volumes. The remote mirror volume is present on a different cluster from the source volume.

Creating remote mirrors is similar to creating local mirrors, except that the mirror volume resides in a different cluster from the source volume. To properly identify the source volume, you must specify the source cluster name when the mirror volume is created. In addition, you must edit the `mapr-clusters.conf` file so that each cluster can resolve the nodes in the other cluster.

To create a mirror on a remote cluster, you must have the same UID for the `MAPR_USER` (the cluster owner) for both the primary cluster (where the source volume resides) and the remote clusters (where the mirror volumes reside; also known as the destination clusters). You also need to have the following volume permissions:

- dump permission on the source volumes
- restore permission on the mirror volumes at the destination clusters

When a mirror volume is created on a remote cluster (according to the entries in the `mapr-clusters.conf` file), the CLDB checks that the local volume exists in the local cluster. If both clusters are not set up and running, the remote mirror volume cannot be created.

To summarize:

- Each cluster must be already set up and running.
- Each cluster must have a unique name.
- Every node in each cluster must be able to resolve all nodes in remote clusters, either through DNS or entries in `/etc/hosts`.
- The UID for the `MAPR_USER` (cluster owner) must be the same for the source and destination clusters, irrespective of which user account triggers the mirror operation.
- Volume permission must be set to `dump` on the source volumes.
- Volume permission must be set to `restore` on the mirror volumes.

See also: [Remote Mirroring](#) on page 571.

Creating a Volume for a Tenant

Provides an overview of how to create a volume for a tenant using the CLI.

About this task

To create a volume for a tenant (when you have [Multitenancy on File System](#) on page 601), do the following:

Procedure

1. Log in to the cluster as administrator and ensure that the ticket for the tenant has already been generated and copied on to the tenant host.
If necessary, follow steps in [Generating a Ticket for a Tenant](#) on page 2107 to set up the ticket for the tenant.
2. Create a volume for the tenant by running the following command:

```
$ maprcli volume create -name <volumeName> -path
<path_to_volume> -tenantuser <tenant_user>
```

NOTE: For more information, see the [maprcli volume create](#) command.

Viewing Volume Information

Describes how to view volume information using either the Control System or the CLI.

About this task

You can retrieve and view volume information using either the Control System or the CLI.

Procedure

1. Log in to the Control System and go to the **Summary** tab in the **Data > Volumes** page.

NOTE: The **Summary** tab is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Click the volume name in the **Volumes** pane.
The volume information page displays. On this page, you can perform the following actions based on the type of the volume.

Standard Volume

Click the **Select Action** drop-down menu to:

- Edit the volume
- [Remove](#) the volume
- [Snapshot](#) a volume
- [Change](#) the mount path and mount or unmount the volume
- [Convert](#) the volume to a mirror volume
- [Rename](#) the volume
- [Manage](#) Label

Mirror Volume

- [Manage](#) Name Space Label

Click the **Select Action** drop-down menu to:

- Edit the Volume
- [Remove](#) the volume
- [Snapshot](#) a volume
- [Start/stop](#) mirroring
- [Promote](#) the volume to a standard (read/write) volume
- [Change](#) volume mount information
- [Rename](#) the volume
- [Manage](#) Label

Tiering Volume

Click the **Select Action** drop-down menu to:

- Edit the Volume
- [Remove](#) the volume
- [Snapshot](#) a volume
- [Change](#) volume mount information
- [Rename](#) the volume
- [Manage](#) Label
- [Offload a volume to a tier](#)
- [Recall a volume from a tier](#)
- [Abort a volume tiering job](#)

The page displays tabs for viewing:

- [Summary](#) of the volume including:
 - All recent and active volume [alarms](#)
 - [Metrics](#) (such as disk usage) for the volume
 - Volume [details](#) such as the general, auditing, and tiering settings for the volume, ACLs and ACEs on the volume, and volume quotas and schedules
 - Labels associated with the volume
- [Snapshots](#) associated with the volume

Viewing Volume Details

Explains how to retrieve and view volume information using the Control System, the CLI, or the REST API.

Viewing Volume Details in the Control System

Procedure

- Log in to the Control System and go to the **Summary** tab in the [volume information page](#) for the volume.

The page displays the following:

Quota Usage

Amount of disk space allocated to and utilized by the volume and associated snapshots. For more information, see [Monitoring Volume Disk Usage Using the Control System](#) on page 1937. You can set or edit hard and advisory quotas by clicking **Edit Quota**. See [Setting or Modifying Quota for a Volume](#) on page 1489 for more information.

Active Alarms

Currently active alarms associated with the volume. For more information, see [Viewing Active Volume Alarms](#) on page 1957. You can [mute](#) or [dismiss](#) alarms by clicking the associated link.

Schedules

The schedules associated with the volume. Standard volumes can have associated snapshot schedule; mirror volumes can have associated snapshot and mirroring schedules; tiered volumes can have associated snapshot and tiering schedules. You can:

- [Create a new schedule](#) by clicking **Create Schedule**.
- [Set new or modify existing schedules](#) by clicking .

Properties

Created By	Indicates the user who created the volume.
Volume Type	Indicates the type of volume. Value can be one of the following: <ul style="list-style-type: none"> • Standard Volume • Mirror Volume
Volume Name	Indicates the name of the volume.
Accountable Entity	Indicates the name of the accountable entity.
Volume Access	Indicates the type of access allowed on the volume. Value can be one of the following: <ul style="list-style-type: none"> • Read/Write • Read-only
Mounted	Indicates whether or not volume is mounted.
Mount Path	Indicates the mount path of the volume.
Collect Metrics	Indicates if metrics collection is enabled for the volume.
Last accessed	Indicates the date when the volume was last accessed.

Last Access Interval	Indicates the frequency (in days) at which the last access time of a file is updated,
-----------------------------	---

Replication and Storage

REPLICATION

Table

Topology	Denotes the location of the volume on the cluster rack.
Replication	Indicates the minimum (Min Target) and desired (Max Target) number of copies for the volume data.
Name Container Replication	Indicates the minimum (Min Target) and desired (Max Target) number of copies of the name container associated with the volume.

Table (Continued)

Optimize Replication	Indicates the basis for replication. Value can be one of the following: <ul style="list-style-type: none">• High throughput, or cascading replication• Low latency, or star replication
Guarantee Min Replication	Indicates whether or not to enforce minimum number of copies.
Actual Replication	Indicates the actual number of replicas as a percentage.

STORAGE

The following information is common to all types of storage:

Table

Type	Indicates the storage type.
Label - Volume	Indicates the label assigned to the volume.
Label - Name Container	Indicates the label assigned to the volume's name container.

Table (Continued)

Usage	Displays disk usage details for the volume.
--------------	---

NOTE: The following is visible only if warm tiering is enabled for the volume.

Table

Topology	Indicates the topology of the erasure-coded volume.
Remote Target	Indicates the name of the tier.
Storage Policy Name	Indicates the name of the storage policy.
Policy Detail	Indicates the rules in the policy for offloading data.
Retention Duration after Recall	Indicates the period of time to keep recalled data in the hot tier.
Erasure Coding Scheme	Indicates the number of data and parity chunks.
Tier Purged	Indicates the amount of offloaded data.

NOTE: The following is visible only if cold tiering is enabled for the volume.

Table

Remote Target	Indicates the name of the remote storage.
Storage Policy Name	Indicates the name of the storage policy.
Policy Detail	Indicates the rules in the policy for offloading data.
Retention Duration after Recall	Indicates the number of days to keep recalled data in the Data Fabric cluster (hot tier).
Tier Purged	Indicates the amount of offloaded data.

Security

Enforcement Mode

The enforcement mode for the security settings. See [Volume-Level Security Policy Enforcement Mode](#) on page 932 for more information. You can [set new or modify existing enforcement mode](#) by clicking .

SECURITY POLICIES

The security policies associated with the volume. See [Policy-Based Security](#) on page 925 for more information.

DATA ACCESS CONTROL

Indicates the entities — public or user, group,

and/or role — that have (read and/or write) access to volume data. See [Managing Access Control Expressions](#) on page 2126 for more information.

AUDIT AND ENCRYPTIONS

Enable Auditing	Indicates whether auditing is enabled at the volume level.
Audit Operations	Indicates whether default or custom list of operations are being audited.
Data on Wire Encryption	Indicates whether (Yes) or not (No) on-wire encryption is enabled for the volume.
Data at Rest Encryption	Indicates whether (Yes) or not (No) data-at-rest encryption (DARE) is enabled for the volume.
Coalesce Interval	Indicates the interval of time (in minutes) used for logging multiple READ, WRITE, or GETATTR operations on one file from one client IP address, if auditing is enabled.

Volume Admin Control

Indicates the users and/or groups who have one or more of the following types of permissions on the volume:

- **Dump & Backup** — Transport large amount of data or copies of the volume on physical media to a remote cluster using backup files.
- **Restore & Mirror** — Restore a volume from a dump file and create mirror volumes, which is a read-only copy of the source volume.
- **Edit** — Edit volume properties, create and delete snapshots.
- **Delete** — Delete the volume.
- **Admin** — View and edit access control settings (but cannot perform other volume administrative operations).
- **Full Control** — Perform all volume-related administrative operations except changing access control settings.

*Viewing Volume Information Using the CLI and the REST API***About this task****CLI**

The basic command to retrieve volume information is:

```
maprcli volume info (-name
<volume_name> | -path <volume_path>)
```

REST

Send a request of type GET. For example:

```
curl -X
GET 'https://<hostname>:8443/rest/
volume/info?name=<volName>' --user
<username>:<password>
```

You must specify either name or path, but not both. For more information, see [volume info](#) on page 2969.

Viewing the list of Snapshots

Describes how to view the list of snapshots that are present on a cluster, using the Control System or the CLI.

About this task

You can view the snapshots on the cluster using the Control System or the CLI.

*Viewing All the Snapshots Using the Control System***Procedure**

- The **Snapshots** tab under the **Data > Volumes** page displays all the snapshots on the cluster.

NOTE: When running on a Kubernetes cluster, the **Snapshots** tab is under the **Volumes** page that is under the **Volumes** menu.

For each snapshot, you can view the following:

Column Name	Column Description
Snapshot Name	The name of the snapshot.
Volume	The volume with which the snapshot is associated.
Created On	The date when the snapshot was created.
Expires On	The date when the snapshot expires.
Reclaim Size	Disk space (in MB) used/owned by the snapshot

You can select one or more snapshots to:

- [Preserve](#)
- [Remove](#)

Viewing the Snapshots Associated with a Volume Using the Control System

Procedure

- Log in to the Control System and go to the **Snapshots** tab in the [volume information page](#).
The list of snapshots associated with the volume displays in this tab. For each snapshot, the pane displays the following:

Column Name	Column Description
Snapshot Name	The name of the snapshot.
Volume	The volume with which the snapshot is associated.
Created On	The date when the snapshot was created.
Expires On	The date when the snapshot expires.
Reclaim Size	Disk space (in MB) used/owned by the snapshot

You can [create a snapshot](#) of the volume or select one or more snapshots to:

- [Preserve](#)
- [Remove](#)

Viewing Snapshots Using the CLI or REST API

About this task

The basic command to retrieve a list of snapshots is:

```
maprcli volume snapshot list
```

For complete reference information, see [volume snapshot list](#) on page 3049.

Removing Volumes

Explains how to remove a volume using either the Control System or the CLI.

About this task

NOTE: When you remove a volume enabled for:

- Cold tiering, the directory/folder for the volume in the metadata volume associated with the tier is also removed asynchronously.
- Warm tiering, the directory/folder for the volume in the metadata volume associated with the tier and the erasure-coded volume are also removed asynchronously.

Removing Volumes Using the Control System

About this task

To remove one or more volumes, in the **Summary** tab under **Data > Volumes**:

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

Procedure

1. Select the volumes to remove from the list of volumes in the **Volumes** pane.

NOTE: Alternatively, you can click the name of the volume to traverse to the volume details page.

2. Click **Remove Volume(s)** from the **Actions** drop-down menu.

The **Remove Volume(s)** confirmation dialog displays.

3. Choose one of the following:

- **Remove only if there are no dependent artifacts** — Specifies whether to check for dependencies before removing the volume. If the volume has dependencies, such as associated snapshots, the volume will not be deleted, but an alarm will be raised.

NOTE: Volume will not be deleted if mirroring is in progress as the mirror volume is synchronized from a hidden internal snapshot of the source volume.

- **Force remove even if there are dependent artifacts** — Indicates that volume must be removed forcefully, even if the volume has dependencies.

4. Click **Remove Volume**.

The selected volumes are removed.

Removing Volumes Using the CLI or REST API

About this task

The basic command to remove a volume is:

```
maprcli volume remove -name <volume name>
```

For complete reference information, see [volume remove](#) on page 3044.

NOTE: When a volume is removed, the data present in that volume is not purged from the filesystem immediately. The following parameters control when the deleted volumes are purged.

- `cldb.purge.delay.hours` — Time to wait (in hours) to trigger purge of any volume after CLDB becomes primary. The default value is 1 hour.
- `cldb.volumes.purge.frequency` — The frequency (in minutes) for purging the data of deleted volumes. The default value is 60 minutes.

Use the `maprcli` command to set these parameters. For example:

```
maprcli config save -values {"cldb.purge.delay.hours":"2"}
maprcli config save -values {"cldb.volumes.purge.frequency":"120"}
```

Modifying Multiple Volumes

Explains how to modify volumes using either the Control System or the CLI.

Modifying Volumes Using the Control System

About this task

To edit multiple volumes, in the **Summary** tab under **Data > Volumes**:

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

Procedure

1. Select the volumes to edit in the **Volumes** pane and click **Edit Volume(s)** from the **Actions** drop-down menu.

The **Edit Volumes** page displays. You can edit certain volume properties, authorization settings, usage settings, and schedule settings for the selected volumes.

2. Modify one or more of the following settings.

NOTE: If the selected volumes share the same settings, the fields are pre-populated with the current value. If the selected volumes contain different settings, only the fields that have been set in all the selected volumes display.

Properties

SETTINGS AND AUDITING	Accountable Entity	The <i>entity</i> accountable for this volume's usage.
	Collect Metrics	Specifies whether (Yes) or not (No) to enable metrics collection for this volume. For more information, see Collecting Volume Metrics on page 1938 and Enabling Volume Metric Collection on page 1939.
	Volume Access	Specifies whether the volume is read-only or a read/write volume. By default, a standard volume is created with read/write access. A mirror volume can only be a read-only volume.
	Last Access Interval	Denotes the frequency at which the access time of a file is updated. See Tuning Last Access Time on page 599 for more information.
	Enable Auditing	Select one of the following: <ul style="list-style-type: none">• Disable auditing• Enable auditing for volume so that auditing can selectively be enabled for directories, files, tables, and streams in the volume• Enable auditing of operations on all files

REPLICATION (HOT)	Replication	Toggle Minimum Replication and set the desired and minimum number of copies of the volumes.
	Name Container Replication	Set the desired and minimum number of copies of the name container associated with the volumes.

SETTINGS AND AUDITING	Accountable Entity	The <i>entity</i> accountable for this volume's usage.
	Collect Metrics	Specifies whether (Yes) or not (No) to enable metrics collection for this volume. For more information, see Collecting Volume Metrics on page 1938 and Enabling Volume Metric Collection on page 1939.
	Volume Access	Specifies whether the volume is read-only or a read/write volume. By default, a standard volume is created with read/write access. A mirror volume can only be a read-only volume.
	Enable Auditing	Select one of the following: <ul style="list-style-type: none">• Disable auditing• Enable auditing for volume so that auditing can selectively be enabled for directories, files, tables, and streams in the volume• Enable auditing of operations on all files, tables, streams in the volume whether or not auditing is enabled for files, tables, and streams in the volume.

REPLICATION (HOT)	Replication	Toggle Minimum Replication and set the desired and minimum number of copies of the volumes.
	Name Container Replication	Set the desired and minimum number of copies of the name container associated with the volumes.

Authorization

ADMINISTRATIVE CONTROLS	Users and groups that have permissions to perform administrative operations on this volume.
-------------------------	---

Usage

Volume Advisory Quota	Allocated disk space, which when exceeded raises an alarm but does not prevent writes.
Volume Hard Quota	Allocated disk space, which when exceeded prevents further writes.

Schedule

Snapshot Schedule	Schedule for creating snapshots of this volume.
Mirror Schedule	Schedule for running mirroring operation for the volumes.  NOTE: This is available only if all the selected volumes are mirror volumes.

NOTE: To undo a change to a specific setting, click the associated . This action will revert the value to the current setting.

3. Click **Save Changes** for the changes to take effect.

Modifying Volumes Using the CLI or REST API

About this task

The basic command to modify a volume is:

```
maprcli volume modify -name <volume name>
```

For complete reference information including supported options, see [volume modify](#) on page 3018.

Modifying a Volume

Describes how to edit volume properties using the Control System, CLI and the REST API.

Modifying a Volume Using the Control System

Procedure

1. Log in to the Control System and go to the [volume information page](#).
2. Click **Edit Volume** to display the **Edit Volume** page.

Modifying General Properties

3. Make changes, as needed, to the following general properties:

Standard Volume

Accountable Entity	The entity accountable for the volume's usage.
Collect Metrics	Whether (Yes) or not (No) to enable metrics collection for the volume.
Volume Access	Indicates whether volume is a read-only or read/write volume.
Last Access Interval	Denotes the frequency at which the access time of a file is updated. See Tuning Last Access Time on page 599 for more information.

Mirror Volume

Source Cluster Name	The name of the cluster on which the source volume exists.
Source Volume Name	The name of the source volume to mirror.
Accountable Entity	The entity accountable for this volume's usage.
Collect Metrics	Whether (Yes) or not (No) to enable metrics collection for the volume.
Volume Access	Indicates whether volume is a read-only (default) or read/write volume. To promote the mirror volume to a standard volume, you can switch to read/write volume; see Changing Mirror Volumes to Standard Volumes on page 1481 for more information.

Last Access Interval	Denotes the frequency at which the access time of a file is updated. See Tuning Last Access Time on page 599 for more information.
-----------------------------	--

Modifying Replication and Storage Settings

4. Make changes, as needed, to the following replication settings:

Topology	The location of this volume in the cluster rack topology.
Guarantee Min Replication	(Available from v6.0.1) Specifies whether (true) or not (false) to enforce minimum number of copies for the (read-write) volume. If this is enabled (Yes), writes succeed only when the minimum number of copies exist.  NOTE: If this parameter was not already set on a volume or if you modify the setting for this property from No to Yes , restart all the nodes where the containers associated with the volume exist for the changes to take effect.
Replication	Desired and minimum number of copies of the volumes.
Name Container Replication	Desired and minimum number of copies of the name container associated with the volumes.

5. Set new (if **Data Tiering** was enabled (**On**) during volume creation) or modify existing **DATA TIERING** settings.

Erasure Coding (Warm)

For offloading data to a warm tier, set new or modify existing values for the following properties.

Topology	The topology of the erasure coded volume from the drop-down list only if it is already not set.
Storage Policy	The rule (or criteria) for automatically offloading data in this volume. You can click: <ul style="list-style-type: none"> • Browse to select an existing rule. • Create to create a new rule for offloading data. See Creating a Storage Tier Policy on page 1564 for more information.

Scheme	The erasure coding scheme, which is the number of data chunks and number of parity chunks, only if it is already not set; you cannot modify existing scheme. See Erasure Coding Scheme for Data Protection and Recovery on page 1504 for more information.
---------------	--

Remote Archiving (Cold)

For offloading data to a low cost storage alternative on the cloud, set new or modify existing values for the following properties.

Storage Policy	The rule (or criteria) for offloading data in this volume. You can click: <ul style="list-style-type: none"> • Browse to select an existing rule. • Create to create a new rule for offloading data. See Creating a Storage Tier Policy on page 1564 for more information.
Remote Target	The location to offload data to only if it is already not set; you cannot modify if it is already set. You can click: <ul style="list-style-type: none"> • Browse to select an existing tier. • Create to create a new tier. See Creating a Storage Tier on page 1548 for more information.
Retention Duration after Recall	The number of days to retain data recalled from the tier to the HPE Data Fabric cluster. Once the number of days is reached, recalled data on the HPE Data Fabric cluster is purged (if there are no changes) or offloaded (if there are changes).

Tier Encryption	The setting to enable (Yes) or disable (No) encryption of data on the tier only if it is already not set.
------------------------	---

Modifying Security Settings

6. Enter the name of the security policy in the **SECURITY POLICIES** field to search for the security policy to associate with the volume and click **Add** to tag the volume with the security policy.
7. Make changes to the auditing settings by moving the slider to **Yes** (to enable) or **No** (to disable).
If enabled (**Yes**), you can make the following changes also:
 - a) Choose the **Default** radio button to enable auditing of a default list of operations or choose the **Custom** radio button to select a custom list of directory, file, table, and streams operations to audit. Note that enabling `setattr` automatically enables `chown`, `chgrp`, and `chperm`. If you exclude `setattr`, these operations are automatically disabled. If you do nothing with `setattr` (neither enable nor disable), you can enable or disable `chown`, `chgrp`, and `chperm` in any combination.
 - b) Specify a **Coalesce Interval**, which is the interval of time (in minutes) to use when logging multiple `READ`, `WRITE`, or `GETATTR` operations on one file from the same client IP address. The default value is 60 minutes.
8. Make changes to the following encryption settings by moving the slider to **Yes** (to enable) or **No** (to disable):

Data on Wire Encryption	Encryption of data in the volume during transmission. By default, this is enabled (Yes) for all new volumes in secure cluster.
Data at Rest Encryption	Encryption of data at rest. This should be enabled only if the feature is enabled at the cluster-level. By default, this is disabled (No).

9. Make changes, as needed, to the users, groups, and/or roles that have and/or do not have permissions to read and/or write by clicking one of the following in the **Data Access Control** section:
 -  — to modify the users, groups, and/or roles.
 -  — to create a copy of the permissions, which you can then modify.
 -  — to remove a data access control setting.
 - Select or deselect **Read** and/or **Write** checkbox in the **Permissions** column — to grant or deny that type of access.
 - **Add Data Access Control** or **Add Another** — to display the **Add Access Permissions** window. To specify the users, groups, and/or roles that have and/or do not have permissions to read and/or write, do the following:
 - a) Move the slider associated with **Public** to **Yes** to grant access to all or to **No** to specify a list of users, groups, and or roles and do one of the following:
 - Enter the users, groups, and/or roles in the respective text boxes.
 - Select the **Custom ACE** checkbox to enter the custom [ACE](#).
 - b) Click **Add** to select permissions for the specified users, groups, and/or roles.

- c) Select the **Read** and/or **Write** checkbox in the **Permissions** column to grant that type of access to all (Public) or the specified users, groups, and/or roles.

Modifying Volume Administration Control Settings

10. Make changes to the users and/or groups that can perform the following administrative operations on this volume:

Dump & Backup	Transport large amount of data or copies of the volume on physical media to a remote cluster using backup files.
Restore & Mirror	Restore a volume from a dump file and create mirror volumes, which is a read-only copy of the source volume.
Edit	Edit volume properties, create and delete snapshots.
Delete	Delete the volume.
Admin	View and edit access control settings (but cannot perform volume operations).
Full Control	Perform all volume-related administrative operations except changing access control settings.

To:

- Modify access for existing users and/or groups, select or deselect permissions.
- Grant access to other users and/or groups, click **Add Another**, enter the user/group name, and select permissions to grant to the user/group.

11. Click **Save Changes** for the changes to take effect.

Modifying a Volume Using the CLI or REST API

About this task

CLI

The basic command to modify a volume is:

```
/opt/mapr/bin/maprccli volume
modify -name <volume name>
```

REST

Send a request of type POST. For example:

```
curl -X POST 'https://<hostname>:8443/
rest/volume/modify?name=<volume
name>' --user <username>:<password>
```

For the complete list of editable parameters, see [volume modify](#) on page 3018.

Renaming a Volume

Describes how to rename a volume using the Control System, CLI or the REST API.

About this task

The rename operation for a volume triggers an unmount and a remount of the volume being renamed. The volume mount path is unavailable for an ongoing IO operation that results in a temporary IO failure.

CAUTION: Data is not written to a volume if you rename the volume in the midst of an IO operation. Stop all clients that are writing data to a volume and ensure that no active IO operations are taking place on the volume, before you rename the volume.

Renaming a Volume Using the Control System

Procedure

1. Log in to the Control System and go the [volume information page](#).
2. Click **Rename Volume** from the **Select Action** drop-down menu to display the **Rename Volume** window.
3. Enter the new name for the volume in the **New Volume Name** field and click **Save Changes** for the changes to take effect.

NOTE: For tiering-enabled volumes, volume name cannot exceed ninety-eight characters.

Renaming a Volume Using the CLI and REST API

About this task

CLI

The basic command to rename a volume is:

```
maprcli volume rename -name
<oldName> -newname <newName>
```

REST

Send a request of type POST. For example:

```
curl -X POST 'https://<host>:8443/
rest/volume/rename?
name=<oldName>&newname=<newName>' --us
er <username>:<password>
```

See [volume rename](#) on page 3045 for more information.

Manage a Label

Describes how to apply a storage label to a volume using the Control System.

Managing a Label Using the Control System

For an overview on Storage Labels, refer to [Using Storage Labels](#) on page 1575.

To apply a label to a volume:

1. Log in to the Control System and go the [volume information page](#).
2. Click **Manage Label** from the **Select Action** drop-down menu to display the **Manage Label** window.
3. Either select an existing label, or enter the name of a label to create, and click **Apply Label** to apply the label to the volume.

Related concepts

Registers a label. Permissions required: fc or a.

[volume create](#) on page 2929

Creates a volume.

[volume move](#) on page 3039

Moves the specified volume or mirror to a different topology. Permissions required: m or fc on the volume.

[label list](#) on page 2555

Lists registered labels. Permissions required: fc or a.

[node list](#) on page 2570

Lists nodes in the cluster.

[dump volumeinfo](#) on page 2468

Returns information about volumes and the associated containers. For JSON formatted output, use the -json option from the command line.

[configure.sh](#) on page 3186

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Data Fabric client nodes, and configuring services for a node.

Manage a Namespace Label

Describes how to apply a label to a namespace container of a volume using the Control System.

Managing a Namespace Label Using the Control System

For an overview of Storage Labels, refer to [Using Storage Labels](#) on page 1575.

To apply a label to a namespace container volume:

1. Log in to the Control System and go the [volume information page](#).
2. Click **Manage Namespace Label** from the **Select Action** drop-down menu to display the **Manage Name Space Label** window.
3. Either select an existing label, or enter the name of a label to create, and click **Apply Label** to apply the label to the namespace container of the volume.

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Data Fabric client nodes, and configuring services for a node.

Specifying Volume Inheritance Using the CLI

Lists volume properties that can be inherited from other volumes.

Volumes can be mounted using the web console, the `maprccli` commands ([volume create](#) or [volume mount](#)), or the REST commands. If the mount point is specified while creating a volume, new volumes can inherit properties from the parent volume. Mirror volumes can also inherit properties from the source volume of the mirror.

Volume inheritance is a convenience that can only be used during volume creation.

The `maprccli volume modify` command can be used to change the volume inheritance settings of a volume. That is, you can toggle the flag (associated with `allowgrant`) that indicates whether a volume, as a parent volume, wants its properties to be inherited by default or not. When creating and mounting a volume, the location of the mount point can be specified using the `path` parameter. The volume that is last in the `path` parameter is referred to as the parent volume. (The parent volume is the volume on which the volume link is created.)

Inheritance applies during volume creation only. If the settings in the parent volume is modified after the child volumes are created, these modified properties do not propagate to the child volumes.

Inheritance

The following table shows the list of inheritable parameters that are (Yes) and are not (No) inherited by a:

- Mirror volume from the source volume on the same cluster
- Mirror volume from the source volume on a different cluster

NOTE: All (non-mirror) volumes inherit all the inheritable properties from the parent volume. For more information on the properties, refer to `volume create` [parameters](#).

Inheritable Properties (which are inherited by non-mirror volumes by default)	Inherited by Mirror Volume on the same cluster as the source volume?	Inherited by Mirror Volume on a different cluster from the source volume?
advisoryquota	Yes	Yes
ae	Yes	No
aetype	Yes	No
allowgrant	Yes	Yes
allowinherit	Yes	Yes
auditenabled	Yes	Yes
coalesce	Yes	Yes

Inheritable Properties (which are inherited by non-mirror volumes by default)	Inherited by Mirror Volume on the same cluster as the source volume?	Inherited by Mirror Volume on a different cluster from the source volume?
dare	Yes	Yes ¹ , No ²
dataauditops	Yes	Yes
dbindexlagsecalarmthresh	Yes	Yes
dbrepllagsecalarmthresh	Yes	Yes
enforcementMode	Yes	Yes
ecscheme	Yes	No
ectopology	Yes	No
group	Yes	Yes
inherit	Yes	Yes
localvolumehost	No	No
localvolumeport	No	No
maxinodesalarmthreshold	Yes	Yes
minreplication	Yes	Yes
mirrorschedule	Yes	No
mirrorthrottle	Yes	Yes
nsminreplication	Yes	Yes
nsreplication	Yes	Yes
ofloadschedule	Yes	No
quota	Yes	Yes
readonly	Yes	Yes
recallexpirytime	Yes	No
replication	Yes	Yes
replicationtype	Yes	Yes
rereplicationtimeoutsec	Yes	Yes
rootdirperms	Yes	Yes
schedule	Yes ³	No
securitypolicy	Yes	Yes
source	Yes	Yes
tierencryption	Yes	No
tieringenable	Yes	No
tieringrule	Yes	No
tierkey	Yes	No
tiername ⁴	Yes	No
topology	Yes	No
type	Yes	Yes

Inheritable Properties (which are inherited by non-mirror volumes by default)	Inherited by Mirror Volume on the same cluster as the source volume?	Inherited by Mirror Volume on a different cluster from the source volume?
user	Yes	Yes
wiresecurityenabled	Yes	Yes

- ¹ If destination cluster is also enabled for data-at-rest encryption, dare setting is inherited by the mirror volume on the destination cluster.
- ² If destination cluster is not enabled for data-at-rest encryption, dare setting is not inherited by the mirror volume on the destination cluster.
- ³ If schedule keyword is specified with the skipinherit parameter, schedule(s) are not inherited while inheriting volume properties from the source volume.
- ⁴ If tiername keyword is specified with the skipinherit parameter:
 - The tiering properties are not inherited by the mirror volume while inheriting volume properties from the tiering-enabled source volume.
 - For volumes enabled for warm-tier, the backend erasure-coded volume is not created.

Setting Data ACEs

Describes how to set ACEs using both the GUI and the CLI.

About this task

To set data [ACE](#) using the **Add Access Permission** window in the Control System:

Procedure

1. Specify the entities to set permissions for by doing one of the following:
 - Move the slider associated with **Public** to **Yes** to grant access to all users or to **No** to set permissions for individual users, groups, and/or roles.
 - Specify the users, groups, and/or roles to set permissions for in the associated fields.
 - Select the **Custom ACE** checkbox and enter the access control expression in the field.
2. Click **Add** to set permissions for all or for the specified users, groups, and/or roles.
3. Select the permissions to grant the specified users, groups, and/or roles from the **Permissions** column associated with the entities.
4. Click **Save Changes** to save the [ACE](#) settings.

Setting Whole Volume ACEs Using the CLI

About this task

See [Setting Whole Volume ACEs](#) on page 1627.

Setting Table ACEs Using the CLI

About this task

See [Enabling Table and Stream Authorizations with ACEs](#) on page 1625.

Setting Stream ACEs Using the CLI

About this task

See [Enabling Table and Stream Authorizations with ACEs](#) on page 1625.

Changing or Setting Mount Information for a Volume

Describes how to set the mount path for a volume using either the Control System, the CLI, or the REST API.

About this task

You can set or change volume mount settings using the Control System, the CLI (`volume create` or `volume mount`), or the REST commands. To mount or unmount volumes under a directory, the user must have read/write permissions on the directory.

Changing or Setting Mount Information for a Volume Using the Control System

Procedure

1. Log in to the Control System and go to the [volume information page](#).
2. Select **Change Mount Information** from the **Select Action** drop-down menu.
The **Change Mount Information** dialog displays.
3. Make the necessary changes.
 - a) Specify whether (**Yes**) or not (**No**) to mount the volume.
 - b) Enter the path in the **Mount Path** field.
The path must be relative to `/` and cannot be in the form of a global namespace path (for example, `/mapr/<cluster-name>/`).

RESTRICTION:

The path should contain only the following characters:

```
A-Z a-z 0-9 _ - .
```

4. Click **Save Changes** for the changes to take effect.

What to do next

NOTE: After changing the mount point, run `maprcli volume fixmountpath` command to notify CLDB of the change in the volume mount path.

Changing or Setting Mount Information Using the CLI or REST API

About this task

The basic command to mount the volume is:

```
maprcli volume mount -name <volume name> -path <mount path>
```

RESTRICTION: The volume name and the path should contain only the following characters:

```
A-Z a-z 0-9 _ - .
```

For complete reference information including all available options, see [volume mount](#) on page 3037.

Mounting one or more Volumes

Explains how to set or change mount settings for volumes using the Control System or the CLI.

About this task

To mount volumes under a directory, you must have read/write permissions on the directory.

Changing or Setting Mount Information Using the Control System

About this task

To mount one or more volumes, in the **Summary** tab under **Data > Volumes**:

Procedure

1. Select the volumes to mount from the list of volumes in the **Volumes** pane.
2. Select **Mount Volume(s)** from the **Actions** drop-down menu.
The **Mount Volume(s)** confirmation dialog displays.

NOTE: Only unmounted volumes with mount paths can be mounted. Volumes with no mount paths and volumes that are currently mounted, if selected, cannot be mounted.

3. Verify list of selected volumes.
If necessary, click to remove a volume from the list of volumes to mount.
4. Click **Mount Volumes** to mount the selected volumes.

Changing or Setting Mount Information Using the CLI or REST API

About this task

The basic command to mount the volume is:

```
maprcli volume mount -name <volume name> -path <mount path>
```

For complete reference information including all available options, see [volume mount](#) on page 3037.

Unmounting one or more Volumes

Describes how to unmount a volume using either the Control System or the CLI.

About this task

You can unmount multiple volumes using the Control System or the CLI. To unmount volumes under a directory, you must have read/write permissions on the directory.

Unmounting one or more Volumes Using the Control System

About this task

To unmount one or more volumes, in the **Summary** tab under **Data > Volumes**:

NOTE: When running on a Kubernetes cluster, the **Summary** tab is in the **Volumes** page under the **Volumes** menu.

Procedure

1. Select the volumes to unmount from the list of volumes in the **Volumes** pane.

2. Select **Unmount Volume** from the **Actions** drop-down menu.
The **Unmount Volume** confirmation dialog displays.

NOTE: Only mounted volumes can be unmounted. Volumes that are currently not mounted, if selected, cannot be unmounted.

3. Verify list of selected volumes.
4. Click **Unmount Volumes** to unmount the selected volumes.

Unmounting one or more Volumes Using the CLI or REST API

About this task

The basic command to unmount the volume is:

```
maprcli volume unmount -name <volume name>
```

For complete reference information including all available options, see [volume unmount](#) on page 3070.

Mounting a Tenant Volume

Describes the steps to mount and access a tenant volume.

About this task

After the tenant volume is created on the cluster (for a [multi-tenant environment](#)), access the tenant volume on the tenant host with the following steps:

Procedure

1. Log in to the tenant host as the tenant admin (root) and verify that a valid tenant ticket is available on the tenant host.

For example, run the following command:

```
~tenantAdmin@tenantHost: maprlogin print -ticketfile /user/tenantAdmin/tenant_sample_ticket.txt
Opening keyfile /user/tenantAdmin/tenant_sample_ticket.txt
cHost: user = sampleTenant, created = 'Mon Jul 11 07:14:53 UTC 2016',
expires = 'Mon Jul 11 07:14:53 UTC 12016', RenewalTill = 'Mon Jul 11 07:14:53 UTC 12016',
uid = 500, gids = 500, 42, CanImpersonate = true, tenant = true
```

2. Perform one of the following:
 - Set up the FUSE-based POSIX client configuration parameters (see [Configuring HPE Data Fabric FUSE-based POSIX Client for Tenant Environment](#) on page 1889) and mount the volume (see [Mounting the File System](#) on page 1894).
 - Set up an alias for NFS exports to export the tenant volume path (see [Setting Up Aliases for NFS Exports](#) on page 1819) and mount the volume for loopbacknfs service (see [Starting the mapr-loopbacknfs Service to Access a Cluster](#)).
3. Create accessible directories within the provisioned space for the tenant users.

Unmounting a Tenant Volume

Explains how unmount a tenant volume using the CLI.

About this task

Procedure

To unmount a tenant volume and:

- Kill the FUSE process, run the following command:

```
service mapr-posix-client-* stop
```

When you run the command, replace * with basic or platinum, which corresponds with the POSIX client package that is installed on the system.

NOTE: For more information, see [Unmounting the FUSE Mount](#).

- Stop the loopbacknfs service, run the following command:

```
service mapr-loopbacknfs stop
```

NOTE: For more information, see [Managing the mapr-loopbacknfs Service](#) on page 1872

Changing Volume Type

You can convert a standard volume to a mirror volume and promote a mirror volume to a standard volume.

A standard volume with one or more associated mirror volumes can be converted to a mirror volume that mirrors one of the its associated mirror volumes. The mirror volume that the converted standard volume is set to mirror must then be promoted to a standard volume. The converted standard volume then becomes a read-only copy of the promoted mirror volume.

NOTE: Standard volumes that do not have one or more associated mirror volumes cannot be converted to mirror volumes.

A mirror volume is a read-only physical copy of a standard volume. In general, mirror volumes are created for the purpose of preventing or minimizing data loss. Mirror volumes are also used to improve performance or to make copies of data for use in other clusters without impacting production. Mirror volumes can be changed to read-write volumes by converting the mirror volumes to standard volumes.

The following topics include procedures for converting a standard volume to a mirror volume and vice versa.

Changing a Standard Volume to a Mirror Volume

Describes how to convert a standard volume to a mirror volume.

About this task

You can convert a standard volume to a mirror volume and set it up to mirror one of its associated mirror volumes using the Control System, the CLI, or the REST API.

Changing a Standard Volume to a Mirror Volume Using the Control System

Procedure

1. Log in to the Control System and go to the [Viewing Volume Details](#) on page 1452 page for the standard volume.
2. Select **Make Mirror Volumes** from the **Select Action** drop-down menu.
The **Mirror Volume** confirmation dialog displays.
3. Select the:

- Name of the source cluster where the associated mirror volume that the converted volume will mirror, exists.
- Name of the source volume that the converted volume will mirror, from the list of associated mirror volumes.

The standard volume, when converted, can only be a mirror of one of its associated mirror volumes.

4. Click **Save Changes** for the changes to take effect.

NOTE: It might take some time (approximately 10 minutes or so) to convert a standard volume to a mirror volume. You need to wait until the operation is complete before performing other actions.

What to do next

After converting the standard volume to a mirror volume:

1. Convert the source (mirror) volume to a standard (read/write) volume to prevent a deadlock and to allow writes to continue on the volume.
2. Associate a mirroring schedule with this volume to ensure that data on this volume is in sync with the source volume.

Changing a Standard Volume to a Mirror Volume Using the CLI or the REST API

About this task

CLI

To convert a standard volume to a mirror volume from the CLI, run the `maprcli volume modify` command with the `-type` option value set to `mirror`.

```
maprcli volume modify -name <volume name> -type mirror
```

REST

To convert a standard volume to a mirror volume, send a request of type POST. For example:

```
curl -k -X POST 'https://<hostname>:8443/rest/volume/modify?name=<volName>&type=mirror' --user mapr:mapr
```

For more information, see [volume modify](#) on page 3018.

NOTE: It might take some time (approximately 10 minutes or so) to convert a standard volume to a mirror volume. You need to wait until the operation is complete before performing other actions.

After converting the standard volume to a mirror volume:

1. Convert the source (mirror) volume to a standard (read/write) volume to prevent a deadlock and to allow writes to continue on the volume.
2. Associate a mirroring schedule with this volume to ensure that data on this volume is in sync with the source volume.

Changing Mirror Volumes to Standard Volumes

Describes how to convert a mirror volume to a standard volume.

About this task

To change read-only mirror volumes to read-write (standard) volumes, you must promote the mirror volumes to standard volumes. After the mirror volume is promoted, the snapshot schedule specified for the mirror is used for the promoted read-write volume and the mirror schedule is disabled. You can promote a mirror volume to a standard volume using the Control System or the CLI.

NOTE: When you use promotable mirrors, the volumes on the destination cluster must be set up in the same way as on the primary site. This means that volume names are the same and mount points are the same. If a hierarchical mounting structure (such as /A/B) is used on the primary site, the same structure must be recreated once mirror volumes are promoted at the secondary site.

Mirror promotion time is typically negligible, but is dependent on the number of containers in the volume being promoted. For a volume with thousands of containers and a few terabytes of data, it may take a few seconds. For enormous volumes with tens of thousands of containers and hundreds of terabytes of data, promotion could take a few minutes.

After the promotion is complete, a status message is logged in the `cldb.log` file with the time taken. For example:

```
2021-06-27 22:47:00,563 INFO VolumeMirrorInfo [VolumeMirrorThread0]:
    Volume conversion successfully completed for volume
    v100k.m@c.228toMirror false.
    Time taken : 142395ms
```

Changing Multiple Mirror Volumes to Standard Volumes Using the Control System

About this task

To change one or more mirror volumes to standard volumes, in the **Summary** tab under **Data > Volumes**:

NOTE: The **Summary** tab is under the **Volumes** menu in the Kubernetes version of the Control System.

Procedure

1. Select the mirror volumes to promote from the list of volumes in **Volumes** pane.
2. Select **Change to Standard Volume(s)** from the **Actions** drop-down menu.
The **Change to Standard Volume(s)** confirmation dialog displays.
3. Review the list of mirror volumes to promote and click **Change Volume(s)** to change the mirror volumes to standard volumes.

What to do next

NOTE: Mirror volumes that are promoted to standard (read-write) volumes are not available for write operations until they are mounted explicitly. For more information, see [Handling Mount Points in Promoted Mirror Volumes](#) on page 1483.

Changing a Mirror Volume to a Standard Volume Using the Control System

Procedure

1. Log in to the Control System and go to the [volume information page](#) for the mirror volume.
2. Select **Change to Standard Volume(s)** from the **Select Action** drop-down menu.
The **Change to Standard Volume(s)** confirmation dialog displays.

3. Click **Change Volume(s)** to change the mirror volume to a standard volume.

What to do next

NOTE: Mirror volumes that are promoted to standard (read-write) volumes are not available for write operations until they are mounted explicitly. For more information, see [Handling Mount Points in Promoted Mirror Volumes](#) on page 1483.

Changing a Mirror Volume to a Standard Volume Using the CLI or REST API

About this task

For changing a mirror volume to a standard (read/write) volume using the CLI, run the `maprccli volume modify` command with the `-type` option value set to `rw` on the cluster where the mirror volume resides and specify the name of the mirror volume that is being promoted. In the following example, the mirror volume is named `volA`:

```
Cluster2> maprccli volume modify -name volA -type rw
```

For more information, see [volume modify](#) on page 3018.

What to do next

NOTE: Mirror volumes that are promoted to standard (read-write) volumes are not available for write operations until they are mounted explicitly. For more information, see [Handling Mount Points in Promoted Mirror Volumes](#) on page 1483.

Handling Mount Points in Promoted Mirror Volumes

Explains how to use mount points in promoted mirror volumes.

After you promote read-only mirror volumes to read-write standard volumes, you must re-establish the mount points that were set up in the source cluster. To understand the steps in this process, consider the following scenario:

A source cluster has volumes A, B, and C, which are mounted at `/A`, `/A/B`, and `/A/B/C` respectively. Each source volume is mirrored to a volume in another cluster (the destination cluster). The names of the corresponding mirror volumes are also A, B, and C.

NOTE: When you use promotable mirrors, the volumes on the destination cluster must be set up in the same way as on the primary site. This means that volume names are the same and mount points are the same. If a hierarchical mounting structure (such as `/A/B`) is used on the primary site, the same structure must be recreated once mirror volumes are promoted at the secondary site.

Mirror volume A is mounted at `/A`, but since the mirror is read-only, no mount point can be created beneath it for mirror B or mirror C.

WARNING: Mirror volumes that are promoted to standard (read-write) volumes are not available for write operations until they are mounted explicitly.

Now suppose that all three mirror volumes are promoted to read-write volumes. Before any data can be written to these volumes, the volume links must be removed and the volumes must be remounted. The commands for each step are as follows:

1. Promote A, B, and C to read-write volumes.

```
Cluster2> maprcli volume modify -name A -type rw
Cluster2> maprcli volume modify -name B -type rw
Cluster2> maprcli volume modify -name C -type rw
```

To promote using the Control System, see [Changing Mirror Volumes to Standard Volumes](#) on page 1481.

2. Remove the volume links located at /A/B and /A/B/C. Since mirror A was already mounted, its volume links do not need to be removed.

```
maprcli volume link remove -path /A/B
maprcli volume link remove -path /A/B/C
```

3. Mount the promoted read-write volumes B and C at the same mount points used in the primary (source) cluster, in order to maintain an exact replica in the destination cluster.

```
Cluster2> maprcli volume mount -name B -path /A/B
Cluster2> maprcli volume mount -name C -path /A/B/C
```

To mount using the Control System, see [Mounting one or more Volumes](#) on page 1478.

Now the promoted volumes are accessible for write operations.

Selecting a Replication Type for High Availability

Describes replication types for high-availability clusters, and the tradeoffs of using them.

HPE Data Fabric volumes, stored as pieces called containers, are replicated, typically three times, on separate nodes to protect data and provide uninterrupted access to data in the event of a node failure. Since all form of data is replicated, in the event of a node failure, after a brief delay while the failure is being detected, clients are simply directed to a replica, which serves as an alternative location for a data object, to continue normally. The latency as a result of the failure being detected can be reduced by adjusting the number of TCP retries. Furthermore, selecting a container replication type that is appropriate for your cluster layout allows for faster replication of container state, which in turn allows for retrieval of the most current data in the event of a node failure.

HPE Data Fabric supports two types of container replication -- high-throughput or cascading replication, where volumes are replicated sequentially on intermediate and tail containers and low-latency or star replication, where volumes are replicated on multiple containers in parallel.

NOTE: For more information, see [How file system and Associated Services Work](#).

The tradeoffs between the replication types is one of latency and throughput. While the low-latency replication delivers relatively lower throughput than the high-throughput replication, the high-throughput replication suffers from relatively higher latencies than the low-latency replication. Another advantage of low-latency replication is that since the primary container is connected to all other replica containers, there is no need to failover a replica container in the event of a failure thus reducing the duration of recovery. However, with high-throughput replication, in the event of a failure of an intermediate container, clients may experience increased latency while CLDB, after detecting the failure, attempts to update the replication chain by making the next or tail container (whichever comes immediately after the failed container) as the next container in the chain.

Converting Volume Replication Type (Low Latency to High Throughput) Using the CLI

Lists the process to convert a volume's replication type using the CLI.

About this task

A high throughput replication type allows for volumes to be replicated sequentially on intermediate and tail containers from a primary container.

To convert from a low-latency to a high throughput-replication type:

Procedure

1. Change the permissions on the volume from read-write to read only.
For example:

```
maprcli volume modify -name mvol1,mvol2 -readonly true
```

Wait for the running operations to complete before proceeding to the next step.

- Convert the volume from `low_latency` replication type to `high_throughput` replication type using the `maprccli` command.

For example:

```
maprccli volume modify -name mvol1,mvol2 -replicationtype high_throughput
```

Wait till replication type conversion is complete and the first container of the volume acquires a primary container. If necessary, run the following command to see if replication type has been converted:

```
maprccli volume list -columns ReplTypeConversionInProgress,volumename
```

If the conversion is complete, the `ReplTypeConversionInProgress` flag will be set to false (0). For example, the 0 in the `ReplTypeConversionInProgress` column in the following sample output indicates successful conversion of corresponding volume in the `volumename` column:

```
maprccli volume list -columns ReplTypeConversionInProgress,volumename
ReplTypeConversionInProgress
volumename

3. Reset the permissions on the volume to read-write.
For example, to reset, run the following command:

```
maprcli volume modify -name vol1,vol2 -readonly false
```

Converting Volume Replication Type (High Throughput to Low Latency) Using the CLI

Lists the process to convert the replication type of a volume using the CLI.

About this task

A low latency replication type allows for volumes to be replicated on multiple containers (in parallel) from the primary container.

NOTE: Contact HPE Data Fabric support before converting volumes to the `low_latency` replication type.

To convert from a high-throughput to a low-latency replication type:

Procedure

1. Change the permissions on the volume from read-write to read only.
For example:

```
maprcli volume modify -name mvol1,mvol2 -readonly true
```

Wait for the running operations to complete before proceeding to the next step.

- Convert the volume from `high_throughput` replication type to `low_latency` replication type using the `maprcli` command.

For example:

```
maprcli volume modify -name mvol1,mvol2 -replicationtype low_latency
```

Wait till replication type conversion is complete and all the containers of the volume acquire a primary container. If necessary, run the following command to see if replication type has been converted:

```
maprcli volume list -columns ReplTypeConversionInProgress,volumename
```

If the conversion is complete, the `ReplTypeConversionInProgress` flag will be set to false (0). For example, the 0 in the `ReplTypeConversionInProgress` column in the following sample output indicates successful conversion of corresponding volume in the `volumename` column:

```
maprcli volume list -columns ReplTypeConversionInProgress,volumename
volumename
ReplTypeConversionInProgress
mapr.apps                                0
mapr.cldb.internal                       0
mapr.cluster.root                        0
mapr.configuration                       0
mapr.doc22.lab.local.audit               0
mapr.doc22.lab.local.logs                 0
mapr.doc22.lab.local.mapred               0
mapr.doc22.lab.local.metrics              0
mapr.doc23.lab.local.audit               0
mapr.doc23.lab.local.logs                 0
mapr.doc23.lab.local.mapred               0
mapr.doc23.lab.local.metrics              0
mapr.hbase                               0
mapr.metrics                             0
mapr.opt                                 0
mapr.resourcemanager.volume              0
mapr.tmp                                  0
mapr.var                                  0
users                                    0
```

- Reset the permissions on the volume to read-write. For example, to reset, run the following command:

```
maprcli volume modify -name vol1,vol2 -readonly false
```

Setting or Modifying Quota for a Volume

Describes how to set or modify a quota for a volume.

About this task

You can set hard and advisory quotas for a volume using the Control System, CLI, and REST API. Hard quota is the total space allocated for the volume irrespective of the location (cluster or tier) where the volume data is stored. When the threshold for the hard quota is reached, an alarm is raised and further writes are not allowed. Advisory quota does not prevent further writes when the threshold is reached, but an alarm is raised.

Setting Quota for a Volume Using the Control System

About this task

You can set quota for a volume in the Volumes page and set or modify quotas for a volume in the volume information page.

Setting Quota for a Volume in the Volumes Page

Procedure

1. Log in to the Control System and click **Data > Volumes** to display the **Volumes** page.

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Ensure that the **Quota** column is displayed in the **Volumes** pane.
If necessary, customize the columns to see the **Quota** column.
3. Click the **Set Quota** link associated with the volume for which you want to set quotas to display the **Set Quota** window.
4. Specify the following in the **Set Quota** window:
 - a) Hard quota, which raises an alarm when the threshold is reached and prevents further writes.

NOTE: When you set a hard quota for a tiering-enabled volume, the quota is the total space allocated for the volume irrespective of the location (cluster or tier) where the volume data is stored. For example, if you allocate 1GB of hard quota for a tiering-enabled volume, writes will fail after you write 1GB of data whether or not the volume data is local (on the cluster) or offloaded (to the tier).

- b) Advisory quota, which raises an alarm when the threshold is reached, but does not prevent further writes.

NOTE: Both, advisory and hard, quotas can be expressed in megabytes (MB), gigabytes (GB), terabytes (TB), petabytes (PB), exabytes (EB), and zettabytes (ZB).

5. Click **Save Changes** for the changes to take effect.

Setting or Modifying Quotas for a Volume in the Volume Information Page

Procedure

1. Log in to the Control System and go the **Summary** tab in the [volume information page](#).
2. Click the **Edit Quota** in the **Quota Usage** pane to display the **Set Quota** window.
3. Specify the following in the **Set Quota** window:
 - a) Hard quota, which raises an alarm when the threshold is reached and prevents further writes.

NOTE: When you set a hard quota for a tiering-enabled volume, the quota is the total space allocated for the volume irrespective of the location (cluster or tier) where the volume data is stored. For example, if you allocate 1GB of hard quota for a tiering-enabled volume, writes will fail after you write 1GB of data whether or not the volume data is local (on the cluster) or offloaded (to the tier).

- b) Advisory quota, which raises an alarm when the threshold is reached, but does not prevent further writes.

NOTE: Both, advisory and hard, quotas can be expressed in megabytes (MB), gigabytes (GB), terabytes (TB), petabytes (PB), exabytes (EB), and zettabytes (ZB).

4. Click **Save Changes** for the changes to take effect.

Setting Quota for a Volume Using the CLI or the REST API

About this task

You can set quotas for a volume when creating a new or modifying an existing volume.

CLI

The basic command to set quota for a volume is:

```
maprcli volume
create -name <volName> -path
<mountPath> -advisoryquota
<advisoryQuota> -quota <hardQuota>
```

```
maprcli volume
modify -name <volName> -advisoryquota
<advisoryQuota> -quota <hardQuota>
```

REST

Send a request of type POST. For example:

```
curl -X POST 'https://<hostname>:8443/
rest/volume/create?
name=<volName>&path=<mountPath>&adviso
ryquota=<advisoryQuota>&quota=<hardQuo
ta>' --user <username>:<password>
```

```
curl -X POST 'https://<hostname>:8443/
rest/volume/modify?
name=<volName>&advisoryquota=<advisory
Quota>&quota=<hardQuota>' --user
<username>:<password>
```

For the complete list of required and optional parameters, see [volume create](#) on page 2929 and [volume modify](#) on page 3018.

Migrating a Volume off a Node Using the CLI

When you need to migrate a data volume off a particular node, move that node from the /data path to the /decommissioned path to avoid data under-replication.

- Establish a /data topology path to serve as the default topology path for the volumes in that cluster.
- Establish a /decommissioned topology path that is not assigned to any volumes.

TIP: It is recommended that CLDB and ZooKeeper nodes are not in the same topology as the data nodes to ensure fast failover of the failed data node in the event of a data node failure.

Since no data volumes are assigned to the /decommissioned topology path, standard data replication will migrate the data off that node to other nodes that are still in the /data topology path.

You can run the following command to check if a given volume is present on a specified node:

```
maprcli dump volumenodes -volumename <volume> -json | grep <ip:port>
```

Run this command for each non-local volume in your cluster. Once all the data has migrated off the node, you can decommission the node or place it in maintenance mode.

If you need to segregate CLDB data, create a `/cldb` topology node and move the CLDB nodes under `/cldb`. Point the topology for the CLDB volume (`mapr.cldb.internal`) to `/cldb`. See [Isolating CLDB Nodes](#) for details.

NOTE: To move an existing volume to another topology, you must have the [Converged Enterprise Edition](#). Without the Converged Enterprise Edition, when you run the `maprcli volume move` command to move a volume to another topology, the following error message is returned:

```
ERROR (10010) - Volume Move: No license for requested operation
```

Setting Up Volume Topology

Specifies how to use volume topology to place volumes on specific racks, nodes, or groups of nodes.

After you define the node topology for the nodes in your cluster, you can use volume topology to place volumes on specific racks, nodes, or groups of nodes.

This section describes the process of setting up:

- Default volume topology
- Local volume topology
- Custom topology for local volume replicas

Setting Up Volume Topology

Explains how to setup Volume Topology using either the Control System or the CLI.

About this task

HPE Data Fabric supports data placement control, in which you can place a volume on specific racks, nodes, or groups of nodes by setting its topology to an existing node topology. You can set volume topology using the Control System or with the [volume move](#) on page 3039 command.

To move an existing volume to another topology, you must have the [Converged Enterprise Edition](#) installed on your system. Without the Converged Enterprise Edition, when you try to move a volume to another topology, the following error message is returned:

```
ERROR (10010) - Volume Move: No license for requested operation
```

Setting Up Volume Topology Using the Control System

About this task

You can set up volume topology at the time of volume creation or change the volume topology after volume creation. To:

- Set up volume topology at the time of volume creation, see [Creating a Volume](#) on page 1437.
- Modify volume topology, see [Modifying a Volume](#) on page 1467.

Setting Up Volume Topology Using the CLI or REST API

About this task

To move a volume to a different topology, run the following command:

```
maprcli volume move -name <volume name> -topology <path>
```

For complete reference information, see [volume move](#) on page 3039.

Setting the Topology for Local Volume Replicas

Explains how to set the topology for local volume replicas using the CLI.

About this task

The primary copies for containers of local volumes are placed on the local node (specified with parameter `-localhost` in the `volume create` command). The nodes for the replica copies for containers of local volumes are chosen as follows:

Procedure

1. If a topology is explicitly specified for replicas during `volume create` or `volume edit`, that topology will be used.

```
maprcli volume create -name egLocalVol -path /test/local/volumes/
examples/sample1 \
-localvolumehost 10.20.30.40 -topology /rack1/test
```

In the above example, the primaries for the volume are placed on node 10.20.30.40, and replicas will be placed on nodes in the topology `/rack1/test`.

The `-topology` parameter is optional, and if it is not specified, CLDB will fall back to 2 or 3 below.

2. If the configuration parameter that specifies a relative path for replicas of local volumes is set, that will be used.

```
maprcli config save -values
{"cldb.local.volume.topology.trim.index":"-1"}
```

This will trim the topology of the node specified by the `localhost` parameter and restrict the replicas to the resultant topology.

By default, this configuration parameter is not set. To set this configuration parameter, see [Creating Replicas of Local Volumes in Custom Topology Using the CLI](#) on page 1493. If the configuration parameter is not set, CLDB will fall back to 3 below.

3. The default volume topology will be used.

The default volume topology is the value specified by the configuration parameter `cldb.default.volume.topology`. The default value for this parameter is `/data`. See [Setting Default Volume Topology Using the CLI](#) on page 1494.

Creating Replicas of Local Volumes in Custom Topology Using the CLI

To set the configuration parameter for placing replicas of volumes in a topology relative to the local node, run the `maprcli config save` command. The value can be a:

- Positive number to indicate the number of paths to keep from the initial root (of the topology path). For example:

```
maprcli config save -values {"cldb.local.volume.topology.trim.index":"1"}
```

- Negative number to indicate the number of paths to skip from the end of the topology path. For example:

```
maprcli config save -values {"cldb.local.volume.topology.trim.index":"-2"}
```

For example, suppose the local volume is created on a node that is under the topology `/data-center1/lab2/rack3/shelf4/10.10.20.30`. To create a local volume where the replicas are restricted to `/data-center1/lab2/rack3` topology, run the following command:

```
maprcli config save -values {"cldb.local.volume.topology.trim.index":"3"}
maprcli volume create -name egLocalVol -path /data-center1/lab2/rack3/
shelf4/10.10.20.30 -localvolumehost 10.10.20.30
```

Alternatively, you can run the following command to specify the path for the volume from the end of the topology path:

```
maprcli config save -values {"cldb.local.volume.topology.trim.index":"-2"}
maprcli volume create -name egLocalVol -path /data-center1/lab2/rack3/
shelf4/10.10.20.30 -localvolumehost 10.20.30.40
```

The replicas for containers of the volume, `egLocalVol`, will be created on nodes under `/data-center1/lab2/rack3`.

Setting Default Volume Topology Using the CLI

Use the `config save` command to set the default topology for volumes.

By default, new volumes are created with a topology of `/data`. To change the default topology, use the [config save](#) on page 2394 command to change the `cldb.default.volume.topology` configuration parameter. Example:

```
maprcli config save -values "{\"cldb.default.volume.topology\":\"/data/
rack02\"}"
```

After this command is run, new volumes have the volume topology `/data/rack02` by default, which could be useful to restrict new volume data to a subset of the cluster.

Changing the Volume Topology

Describes how to move a volume from one topology to another using the Control System or the CLI.

Changing the Topology of a Volume Using the Control System

About this task

Procedure

1. Go to the [Viewing Volume Details](#) on page 1452 page, and select a volume.
The **Change Topology** dialog displays, showing the current topology value.
2. Enter the new value for the topology.
3. Click **Save Changes** for the changes to take effect.

Changing the Topology of a Volume Using the CLI or REST API

About this task

The basic command to move a volume to a different topology is:

```
/opt/mapr/bin/maprcli volume move -name <volume name> -topology <topology>
```

For complete reference information, see [volume move](#) on page 3039.

Viewing Active Volume Alarms

Describes how to view volume alarms using the Control System and the CLI.

About this task

You can view volume alarms in the Control System and using the CLI.

Viewing Active Volume Alarms in the Control System

Procedure

- Log in to the Control System and:
 - Click **Data > Volumes** to view all active volume alarms in the **Active Alarms** pane.
-  **NOTE:** The **Volumes** page is under the **Volumes** menu on the Kubernetes version of the Control System.
- Go to the **Summary** tab in the [volume information page](#) to view the recent and active alarms for the selected volume in the **Alarms** pane.
 - Click  (in the top navigation bar) and select **Volume Alarms** from the drop-down menu in the **All** alarms pane to view all the active volume alarms.
 - Click **Overview** and select **Volume Alarms** from the drop-down menu in the **Active Alarms** pane to view all active volume alarms.

You can:

- [View](#) information related to the alarm.
- [Dismiss](#) an alarm.
- [Mute](#) an alarm.

See [Volume Alarms](#) on page 3414 for more information on the volume alarms.

Retrieving Active Volume Alarms Using the CLI or REST API

About this task

The basic command to retrieve node alarms is:

```
maprcli alarm list -cluster <cluster name> -type volume
```

For complete reference information, see [alarm list](#) on page 2298.

Working with Mirror Volumes

The mirroring process transmits the differences between the source volume and the mirror. The initial mirroring operation copies the entire source volume, but subsequent mirroring operations are generally very fast. The following sections describe how to manage the mirroring operation.

Changing the Limit for Concurrent Mirror Operations Using the CLI

The system allows a maximum of 50 concurrent mirroring operations by default. Mirroring operations include both mirroring and promoting from read-only mirrors to read-write standard volumes. The system parameter that controls this limit is `mapr.mirror.concurrent.ops`. This system parameter is set on the destination cluster.

For large-scale mirror operations involving many volumes, a script automates the process. For example, if a script queues 100 volumes for mirroring operations, and the `mapr.mirror.concurrent.ops` limit is set to 50, the mirroring operations start on the first 50 volumes in the queue. As soon as one volume completes, another volume is processed from the queue until all 100 are completed. Since volumes

are processed from the queue in first-in first-out (FIFO) order, the script should specify the most critical volumes first.

If you want to process more volumes at a time, you can raise the limit of the `mapr.mirror.concurrent.ops` parameter. To tune this parameter for maximum efficiency, consider the number of containers per volume. A higher number of containers per volume requires a lower limit than a lower number of containers per volume. To raise the limit to 500 for example, run the following command on the destination cluster:

```
maprcli config save -values {"mapr.mirror.concurrent.ops":"500"}
```

Pushing Changes to Mirrors Using the CLI

To *push* a mirror means to start pushing data from the source volume to all of its local mirrors. You can push source volume changes out to all mirrors using the `volume mirror push` command, which returns after the data has been pushed.

Moving Large Amounts of Data to a Remote Cluster Using the CLI

You can use the `volume dump create` command to create volume copies for transport on physical media. The `volume dump create` command creates backup files containing the volumes, which can be reconstituted into mirrors at the remote cluster with the `volume dump restore` command. Associate these mirrors with their source volumes with the `volume modify` command to re-establish synchronization.

Another way to transfer large amounts of data to a remote cluster is to create a small cluster locally and mirror to that local cluster. Then move that cluster to a remote location and enlarge it by adding more nodes.

Disabling Mirror Throttling Using the CLI

By default, mirror throttling is enabled, which means that the server that sends mirror data, restricts itself to about 30% of the available bandwidth, as measured in HPE Data Fabric's internal environment, with the default settings of the following parameters. Mirror throttling is based on the number of outstanding requests on the network, and outstanding I/O requests on disk, and can be tuned using the parameters, `mfs.disk.iothrottle.count`, `mfs.disk.resynciothrottle.factor`, and `mfs.network.resynciothrottle.factor`, in the `mfs.conf` file. When other processes need more network bandwidth, the server throttles back to slow down the rate of data transfer.

By disabling throttling, the mirror operation completes faster.

To disable mirror throttling from the command line, run the `volume modify` command on the *source* volume and set the `-mirrorthrottle` option to `false`, as shown in this example:

```
/opt/mapr/bin/maprcli volume modify -name volA -mirrorthrottle false
```

This command disables throttling for all mirror volumes whose source is volA. Note that the `-mirrorthrottle` option only applies to volumes that have mirrors.

Recovering Volumes from Mirrors Using the CLI

Lists the process to recover mirror volumes, using the CLI.

1. Use the `volume dump create` command to create a full volume dump for each mirror volume you want to restore. Example: `maprcli volume create -e statefile1 -dumpfile fulldump1 -name volume@cluster`
2. Transport the volume dump to the rebuilt cluster.
3. For each volume on the mirror cluster, set up a corresponding volume on the rebuilt cluster.
 - a. Restore the volume using the `volume dump restore` command. Example: `maprcli volume dump restore -name volume@cluster -dumpfile fulldump1`

- b. Copy the files to a standard (non-mirror) volume.

Starting the Mirror

Explains how to start a mirror operation using either the Control System or the CLI.

About this task

When a mirror starts, all the data in the source volume is copied into the mirror volume. Starting a mirroring operation requires the mirror volume to exist and be associated with a source. After you start a mirror, synchronize it with the source volume regularly to keep the mirror current.

NOTE: The `getIPTypeForCluster` method in `CLDBRpcCommonUtils` is unable to determine whether the IP type is internal or external, if `mapr-clusters.conf` contains both internal and external IPs. The fix is to only put in the internal IP in `mapr-clusters.conf` and keep the external IP in the `env.sh` file, before starting the mirror.

Starting the Mirror for Multiple Mirror Volumes Using the Control System

About this task

To start mirroring, in the **Summary** tab under **Data > Volumes**:

NOTE: The **Summary** tab is under the **Volumes** tab in the Kubernetes version of the Control System.

Procedure

1. Select the mirror volume(s) to synchronize.

You *cannot* start mirror for:

- Standard volumes
- Mirror volumes currently mirroring

2. Select **Start Mirroring** from the **Actions** drop-down menu.

The **Start Mirroring Volume(s)** confirmation dialog displays.

3. Verify the list of volumes to synchronize and click **Start Mirroring**.

When a mirror is started, the mirror volume is synchronized from a hidden internal snapshot so that the mirroring process is not affected by any concurrent changes to the source volume. The changes to the mirror volume occur atomically at the end of the mirroring process; deltas transmitted from the source volume do not appear until mirroring is complete.

Starting the Mirror for a Mirror Volume Using the Control System

About this task

To start mirroring:

Procedure

1. Go to the [volume information page](#) for the mirror volume to synchronize.

2. Select **Start Mirroring** from the **Select Action** drop-down menu.

The **Start Mirroring Volume** confirmation dialog displays.

3. Click **Start Mirroring.**

When a mirror is started, the mirror volume is synchronized from a hidden internal snapshot so that the mirroring process is not affected by any concurrent changes to the source volume. The changes to the mirror volume occur atomically at the end of the mirroring process; deltas transmitted from the source volume do not appear until mirroring is complete.

Starting the Mirror Using the CLI or REST API

About this task

The basic command to start a mirror is:

```
maprcli volume mirror start -name <volume name>
```

For complete reference information, see [volume mirror start](#) on page 3003.

Stopping the Mirror

Explains how to stop a mirror operation using either the Control System or the CLI.

About this task

Stopping a mirror halts any replication or synchronization process currently in progress. Stopping a mirror does not delete or remove the mirror volume.

Stopping the Mirror for Multiple Mirror Volumes Using the Control System

About this task

To stop mirroring, in the **Summary** tab under **Data > Volumes**:

NOTE: The **Summary** tab is under the **Volumes** tab in the Kubernetes version of the Control System.

Procedure

1. Select the mirror volume(s) to stop.

You *cannot* stop the mirror operation for:

- Standard volumes
- Mirror volumes that are currently not mirroring

2. Select **Stop Mirroring** from the **Actions** drop-down menu.

The **Stop Mirroring Volume(s)** confirmation dialog displays.

3. Verify the list of volumes to stop and click **Stop Mirroring**.

When a mirroring operation is stopped, replication or synchronization processes currently in progress will halt.

Stopping the Mirror for a Mirror Volume Using the Control System

About this task

To stop mirroring:

Procedure

1. Go to the [volume information page](#) for the mirror volume to stop.

2. Select **Stop Mirroring** from the **Select Action** drop-down menu.

The **Stop Mirroring Volume** confirmation dialog displays.

3. Click **Stop Mirroring**.

When a mirroring operation is stopped, replication or synchronization processes currently in progress will halt.

Stopping the Mirror Using the CLI or REST API

About this task

The basic command to stop a mirror is:

```
maprcli volume mirror stop -name <volume name>
```

For complete reference information, see [volume mirror stop](#) on page 3017.

Viewing Mirror Status

List mirror volumes and their status using the Control System and the CLI.

You can see a list of all mirror volumes and their current status in the **Mirror Volumes** view (in the Control System, select **Mirror Volumes** from the drop-down menu in the **Volumes** page under **Data > Volumes**) or using the [volume list](#) on page 2989 command. Use the [volume mirror status](#) on page 3004 command to view the details of the mirroring operation that is in progress. The [volume mirror status](#) on page 3004 command helps in troubleshooting the mirroring operation. For more information on troubleshooting mirroring, see the support article titled [Monitor and Understand Volume Mirroring in HPE Data Fabric](#).

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

To use the volume list command to explicitly list mirror volumes, you must define a filter. For example:

```
maprcli volume list -filter [n==<mirror name>] -columns \
    n,p,mirror-percent-complete,mrt -cluster <target cluster>
```

Mirrors and Performance

Completion time for a mirroring operation is affected by the available network bandwidth, and the amount of data to transmit. For best performance, set the mirroring schedule according to the anticipated rate of data changes, and the available bandwidth for mirroring.

Using Promotable Mirrors for Disaster Recovery

The concept of promoting a mirror refers to the ability to make a read-only mirror volume into a read-write volume. The main use case for this feature is to support disaster-recovery scenarios in which a read-only mirror needs to be promoted to a read-write volume so that it can become the primary volume for data storage.

A cluster administrator can perform the following tasks from a remote datacenter before, during, and after a disaster:

- Set up mirroring to a remote cluster
- Fail over to a mirror volume
- Restore the mirror relationship

For a brief overview of the terminology used to describe volume types, along with some basic commands, see the [Types of Volumes](#) on page 566.

The following sections provide information about how to use promotable mirrors for disaster recovery:

Setting up Mirroring to a Remote Cluster

Once data volumes are created in a primary datacenter, the cluster administrator creates mirror volumes in a remote secondary datacenter. The following diagram illustrates the mirror relationship between these two volumes:

NOTE: When you use promotable mirrors, the volumes on the destination cluster must be set up in the same way as on the primary site. This means that volume names are the same and mount points are the same. If a hierarchical mounting structure (such as /A/B) is used on the primary site, the same structure must be recreated once mirror volumes are promoted at the secondary site.

The following sections provides information about how to set up mirroring to a remote cluster:

1. [Creating Remote Mirrors](#) on page 1450
2. [Configuring Secure Clusters for Cross-Cluster Mirroring and Replication](#) on page 2226
3. [Creating a Mirror Volume](#)
4. [Creating a Mirroring Schedule](#)

Failing Over to a Mirror Volume

When a disaster occurs at a primary datacenter, data can no longer be written to the volumes in that location, and the mirror operation cannot be performed. In order to maintain business continuity, the administrator at the secondary datacenter promotes the read-only mirror volume to a read-write volume, which breaks the mirror relationship. At this point, the promoted mirror volume contains all the data that was on the source volume at the time of the most recent successful mirror operation.

The following sections provide information about how to fail over to a mirror volume:

- [Changing Mirror Volumes to Standard Volumes](#) on page 1481
- [Handling Mount Points in Promoted Mirror Volumes](#) on page 1483
- [Changing the Limit for Concurrent Mirror Operations Using the CLI](#) on page 1495

Restoring the Mirror Relationship

Explains how to restore the mirror relationship between the original read-write volume in the primary datacenter and the promoted read-write volume in the secondary datacenter.

About this task

If the primary datacenter comes back online, the administrator can re-establish the mirror relationship between the original read-write volume in the primary datacenter and the promoted read-write volume in the secondary datacenter.

Note that the two read-write volumes will have different data, since data was written to the promoted mirror while the original source volume was down. The original source volume might also have different data that was written after the last mirror operation, but before the cluster went down. The administrator must decide which data to keep and use as the source.

WARNING: Some data loss is inevitable in a disaster recovery scenario. To minimize potential data loss, use mirrors to provide a synchronized copy of each volume with critical data, and in the event of discrepancies, decide which data to preserve based on your company's policies.

The following sections provide information about how to restore the mirror relationship:

Preserving volA/Cluster1's Data

Suppose that volA in the primary datacenter contains crucial data that must be preserved, and you want to mirror its data to volA in the secondary datacenter (the same mirror relationship that was established originally). To recreate the original mirror relationship, convert the promoted volume, volA/Cluster2, from a read-write volume to a mirror of volA/Cluster1 by running the following command:

```
Cluster2> maprcli volume modify -name
volA -type mirror -source
volA@Cluster1
```

To use the Control System to convert volA/Cluster2 from a read-write volume to a mirror of volA/Cluster1, follow steps for [Changing a Standard Volume to a Mirror Volume](#) on page 1480.

Preserving volA/Cluster2's Data on volA/Cluster1

Now suppose you want to preserve the data on volA/Cluster2 (in the remote datacenter) but you still want volA/Cluster1 to be the primary volume with volA/Cluster2 as its mirror. From the command line or the Control System, you can save volA/Cluster2's data on volA/Cluster1 and reestablish the original mirror relationship from volA/Cluster1 to volA/Cluster2.

You can use either of the following methods to preserve the data:

From the Control System

About this task

Complete the following steps from the Control System to save volA/Cluster2's data on volA/Cluster1 and reestablish the original mirror relationship from volA/Cluster1 to volA/Cluster2.

Procedure

1. Stop writing new data to volA/Cluster2 by making this volume read-only:
For detailed steps, see [Modifying a Volume](#) on page 1467.
2. Make volA/Cluster1 a mirror of volA/Cluster2.
For detailed steps, see [Changing a Standard Volume to a Mirror Volume](#) on page 1480.

3. Start mirroring.
For detailed steps, see [Starting the Mirror](#) on page 1497.
4. Promote volA/Cluster1 to a read-write volume.
For detailed steps, see [Changing Mirror Volumes to Standard Volumes](#) on page 1481.
5. Make volA/Cluster2 a mirror of volA/Cluster1.
For detailed steps, see [Changing a Standard Volume to a Mirror Volume](#) on page 1480.

From the Command Line

Procedure

1. Stop writing new data to volA/Cluster2. To be sure no data is written to this volume, make it read-only by running this command:

```
Cluster2> maprcli volume modify -name volA -readonly true
```

2. Pull the data from volA/Cluster2 to volA/Cluster1 by making volA/Cluster1 a mirror of volA/Cluster2.

```
Cluster1> maprcli volume modify -name volA -type mirror -source  
volA@Cluster2
```

3. Start the mirror operation.

```
Cluster1> maprcli volume mirror start -name volA
```

4. Once mirroring is done, promote volA/Cluster1 to a read-write volume. Note that the mirror relationship breaks at this point.

```
Cluster1> maprcli volume modify -name volA -type rw
```

5. Make volA/Cluster2 a mirror of volA/Cluster1.

```
Cluster2> maprcli volume modify -name volA -type mirror -source  
volA@Cluster1
```

Enabling and Restricting Access to Tenant Volume and Data

Describes how to restrict access to tenant volumes in a multi-tenant environment.

About this task

In a [multi-tenant environment](#), the tenant volume (share) can be accessed by all users on the tenant instance by default. To restrict access to specific users and/or groups:

Procedure

1. Log in to the cluster as the cluster administrator and set [ACEs](#) on the volume using the volume commands.

For example:

```
/opt/mapr/bin/maprcli volume modify -name <volumename> -readAce "u:<user>|g:<group>" -writeAce "u:<user>|g:<group>"
```

Here, value for <user> must be the UID of the user and value of <group> must be GID of the group on the tenant host.

TIP: For more information, see [maprcli volume modify](#) command.

2. Log in as the tenant admin and set permissions for data access.

You can set permissions using:

- Linux commands such as `chmod`, `chown`, and so on.
- [ACEs](#), which can be set on files and directories in the volume. For more information, see [Enabling Volume, Directory, and File Authorizations with ACEs](#) on page 2130.

Working with Tiered Volumes

This section describes how to create tiered volumes and manage automatic and manual tiering jobs on the tiered volume.

Erasure Coding Scheme for Data Protection and Recovery

Describes the erasure coding (EC) schemes for data protection and recovery.

Erasure coding (EC) is a data protection method in which data is broken into fragments, expanded and encoded with redundant data pieces, and stored across a set of different nodes or storage media.

EC ensures that if data becomes corrupted, it can be reconstructed using other data and parity fragments.

The time required to reconstruct data depends on the number of data fragments in the chosen EC scheme, and the number of failures that have occurred. For example, reconstruction of EC scheme 10+2 takes longer than the reconstruction of EC scheme 3+2, as a larger number of data and parity fragments must be read.

Following are the types of EC schemes that you can use:

- [EC Schemes Without Local Parity](#): Even for a single failure, for a m+n scheme, the system must read a minimum of m other fragments to reconstruct data.
- [EC Schemes With Local Parity](#): In such schemes, data fragments are logically divided into groups with one local parity fragment per group, hence for a single failure the system reads just the remaining fragments in the affected group, along with the local parity fragment of the affected group, to rebuild data. Rebuilding data for a single failure is much faster on a scheme with a local parity, as a fewer number of fragments must be read.
- Inline Erasure Coding. See [Inline Erasure Coding](#) on page 1529 for details.

NOTE: The value of parity fragment must be a non-zero positive number less than or equal to the number of data fragments.

Considerations When Selecting an EC scheme

As an administrator, consider the following points when selecting an EC scheme:

- How many nodes can you afford to have?

- How many failures might occur? Do you anticipate a single failure, or multiple failures?
- Consider the following when determining how long you are willing to wait for a node to be rebuilt:
 - Rebuilds overhead - For 4+2, you need to read data from 4 nodes to rebuild, for 6+3, you need to read from 6 nodes to rebuild.
 - Reads overhead - For 4+2, you need to read data from 4 nodes, for 6+3, you need to read from 6 nodes. For degraded states, parity calculation overhead is an add-on.
 - Data classification - High ecschemes 10+2 , 12+4, are ideal for archived data, since data mostly remains untouched.

EC Schemes Without Local Parity

In an erasure coded volume, an erasure coding scheme without Local Parity has the stripe layout $m+n$. The stripe is an array of m data fragments and n parity fragments.

Each fragment is called a stripelet. Each stripelet is present on a container and one stripe is across different containers on different nodes. The default stripelet size is 4MB. For an EC scheme 4+2 for example, the stripe size is 24MB.

A Container Group (CG) is collection of such stripes. Based on the maximum size of a container (32 GB), the maximum number of stripes in a CG is 8K.

Each stripe is created by the same number of data fragments from all containers in the group of EC containers. Each container is placed on a different physical node.

- m is the number of data fragments.
- n is the number of redundant fragments (referred to as parity fragments).
- The parity is calculated using data from all data fragments.
- $m/(m+n)$ is the encoding rate.
- $m+n$ is the number of encoded fragments.
- You need to read a minimum of m blocks to recover data.
- You can recover data from a maximum of n failures.

For example, assume $m=4$, $n=2$, and stripe depth=4 MB.

- The number of data fragments is four (4), and while the number of parity fragments is two (2).
- The number of encoded fragments is six (6).
- The stripe size is 16 MB (4x4 MB) of user data, and 8 MB (2x4 MB) of parity fragments.
- The system can handle two (2) failures, and any fragment can be recovered from four (4) other fragments.

Requirements for using an erasure coding scheme without local parity

- The number of data fragments must be between 2 and 10 (both inclusive) for erasure coding scheme without local parity.
- The number of nodes must be greater than or equal to the sum of data and parity fragments.
- The number of parity fragments must be greater than or equal to 1 and less than or equal to the number of data fragments.

Select from the following schemes for erasure-coded volumes:

EC Scheme	Number of Data Nodes	Number of Parity Nodes	Total Number of Nodes Needed	Number of Failures Recoverable	Number of Nodes to Read to Recover Data
2+2	2	2	4	2	2
3+2	3	2	5	2	3
4+2	4	2	6	2	4
5+2	5	2	7	2	5
6+3	6	3	9	3	6
10+<x> where x is a value from 1 to 10	10	x	10+x	x	10

Although you can create a volume without the required number of nodes for a specific scheme, volume offload fails if the required number of nodes are not present.

When choosing the scheme, note that more nodes leads to longer recovery time, resulting in degraded performance, network expense, and lengthy time to rebuild.

If you anticipate only a single failure, use an EC scheme with local parity, as the number of nodes needed to be read for recovery is fewer, when compared to an EC scheme without local parity.

For example, consider a 12 + 4 EC scheme represented as D0 + D1 + D2 + . . . + D10 + D11 + P0 + . . . + P3

Suppose node D4 goes down, now to rebuild, a total of 12 stripelets must be read. This leads to huge performance degradation in network bandwidth, CPU cycles, and Disk IO .

To reduce the reconstruction cost, use EC Local Parity, where the number of stripelets to be read reduces to 6 for a single failure in the 12+2+2 scheme.

IMPORTANT: The recommended number of nodes required for erasure coding is M+2N (rather than M+N) to ensure HPE Data Fabric self-healing and proper operation after N failures. N failures with only M+N nodes allows you to continue reading the data, but with significantly reduced performance because each read requires rebuilding data fragments. Also, manual intervention is required to protect the data from further failures. Currently, data will not be erasure coded if only M nodes are available. With M+2N nodes, N failures will self-heal with no operator intervention.

EC Schemes With Local Parity

Choosing an EC scheme with local parity reduces EC storage overhead without incurring high rebuild costs and longer rebuild times while lowering the probability of data loss. Multiple local parity schemes are supported (for example, 6+2+2, 8+2+2, 10+2+2, 12+2+2, 14+2+2, 16+2+2), as long as the k+g+l constraints are met.

EC Scheme	Number of Data Nodes	Number of Local Parity Nodes	Number of Global Parity Nodes	Total Number of Nodes Needed	Number of Failures Recoverable	Number of Nodes to Read to Recover Data
6+2+2	6	2	2	10	<ul style="list-style-type: none"> 3 all the time 4 most of the time 	<ul style="list-style-type: none"> 3 for a single failure 6 for multiple failures

EC Scheme	Number of Data Nodes	Number of Local Parity Nodes	Number of Global Parity Nodes	Total Number of Nodes Needed	Number of Failures Recoverable	Number of Nodes to Read to Recover Data
8+2+2	8	2	2	12	<ul style="list-style-type: none"> 3 all the time 4 most of the time 	<ul style="list-style-type: none"> 4 for a single failure 8 for multiple failures
10+2+2	10	2	2	14	<ul style="list-style-type: none"> 3 all the time 4 most of the time 	<ul style="list-style-type: none"> 5 for a single failure 10 for multiple failures
12+2+2	12	2	2	16	<ul style="list-style-type: none"> 3 all the time 4 most of the time 	<ul style="list-style-type: none"> 6 for a single failure 12 for multiple failures
14+2+2	14	2	2	18	<ul style="list-style-type: none"> 3 all the time 4 most of the time 	<ul style="list-style-type: none"> 7 for a single failure 14 for multiple failures
16+2+2	16	2	2	20	<ul style="list-style-type: none"> 3 all the time 4 most of the time 	<ul style="list-style-type: none"> 8 for a single failure 16 for multiple failures

The following technical discussion provides more information about local parity schemes.

About Parity Schemes

Local parity is calculated from a subset of data blocks.

Consider a 10+2 scheme *without* local parity.

In this example, if block D6 fails, the system needs to read a minimum of 10 other blocks, to recover data.

Now consider a 10+2+2 scheme with local parity. In this case, data fragments are divided into two (2) data groups, each containing five (5) data fragments, with a local parity for each group. The global parity blocks are common to both data groups. To recover from a single failure, the system must read only the four (4) remaining fragments in the affected data groups, and the corresponding local parity fragment:

In this example, since there is only a single failure in a data group (block D5), the system must only read fragments D1+D2+D3+D4+L1 (which is the local parity fragment of this data group). Recovery is much faster and more efficient, due to the local parity block.

Points to note for using an erasure coding scheme with local parity

- The number of data fragments must be between 2 and 16 (both inclusive) for erasure coding scheme with local parity.
- In an EC scheme represented as $k+g+l$, k is the number of data blocks, g is the number of global parity blocks, and l is the number of local parity blocks.
- You need $k+g+l$ nodes for each local parity scheme.
- k must be divisible by l to get k/l data fragments in each data group. For example, in the 10+2+2 EC scheme, there are $10/2=5$ data fragments in each data group.
- l must be greater than 1.
- k must be greater than $(g+l)$.
- With local parity, the system can recover from 1 to $g+1$ failures at any time. In the 10+2+2 scheme, the system can recover from 1 to 3 failures at any time.
- The system can recover from $g+2$ to $g+l$ failures in certain cases. With the 10+2+2 scheme, the system can recover from 4 failures, in certain cases.
- If none of the data fragments have failed in a data group, the system cannot use the corresponding local parity fragment, to recover from a failures in other data groups. For example:

To recover D5, the system reads only D1+D2+D3+D4+L1. It does not read D1+D2+D3+D4+L2, since there are no failures in the data group D6 to D10, for which L2 is the local parity fragment.

- For a single failure, the system needs to read k/l fragments to recover. For multiple failures, the system needs to read k fragments to recover.

With local parity, the system recovers from most of $g+l$ failures. For the 10+2+2 scheme, the system can recover from most of 4 failures. For example:

Here, there are 4 failures. The required number of blocks to read (10 in this case) are available, for recovery. The system reads $D1+D2+D3+D6+D9+D10+L1+L2+G1+G2$.

However, consider the following example:

Although there are 4 failures, the system does not have the required number of fragments (10) to read and recover. The only fragments that can be read are $D1+D2+L1+D6+D7+D8+D9+D10+G1$. Fragment L2 cannot be read because there are no failures in its corresponding data group D6 to D10. Therefore in this case, data cannot be reconstructed.

Specifying a Schedule for Offloading Data

Explains how to create a schedule for automatic offloading of data, using the Control System, the CLI and the REST API.

About this task

You can create a schedule using the Control System, the CLI, and REST API. After creating a schedule, you can associate it with the tiering-enabled volume when you create or modify the volume. If a schedule for offloading data is associated with the volume, data is offloaded automatically as scheduled based on the rules associated with the volume for offloading data. You can also manually trigger the `maprcLi` command to offload data.

The following schedules are available out-of-the-box for offloading data:

Schedule Name	Schedule ID
Critical data	1
Important data	2
Normal data	3
Automatic Tiering Scheduler	4*

* The Automatic Tiering Scheduler ID might be different on different clusters. To retrieve the correct ID, run the [schedule list](#) on page 2617 command.

For volumes enabled for warm tiering, the Automatic Tiering Scheduler is used by default for offloading data if you do not explicitly assign a schedule. The frequency of the Automatic Tiering Scheduler run is based on two the following:

time	The frequency. The <code>cldb.auto.offload.frequency.minutes</code> property stores the default value of 24 * 60 minutes. This can be configured using the config save on page 2394 command. The value for this property must be in minutes.
size	The amount of data (that has not yet been offloaded) in the volume. The <code>cldb.auto.offload.threshold.gb</code> property stores the global value for the size threshold. The default value for this property is 1024GB, which cannot be modified. However, you can override the global value at the volume-level using the <code>autooffloadthresholdgb</code> parameter with the Creating a Volume on page 1437 and volume modify on page 3018 commands.

The Automatic Tiering Scheduler run is based on the time setting. However, it runs sooner if the size of the volume in the hot tier reaches or exceeds the size threshold.

For volumes enabled for cold tiering, you must assign a schedule to automatically offload data; if you do not assign a schedule, data is not offloaded automatically and you must manually run the offload command to offload data. You can associate the Automatic Tiering Scheduler with the cold-tier enabled volume or create a custom schedule and associate it with the volume to automatically offload data.

To:

- Create a schedule before creating the volume, see [Creating a Schedule](#) on page 1542.
- Create a schedule when you are creating the volume, see step 9 in [Creating a Volume](#) on page 1437.

Specifying a Schedule Using the Control System

About this task

You can associate a schedule with a tiering-enabled volume when you are:

- Creating a volume by clicking **Create Volume** button in the **Data > Volumes** page.
- Editing the tiering-enabled volume by clicking **Edit Volume** button in the [volume information page](#).

Specifying a Schedule Using the CLI and REST API

About this task

You can associate a schedule with a tiering-enabled volume by specifying the `offloadschedule` parameter with the [volume create](#) on page 2929 or [volume modify](#) on page 3018 command.

CLI

Run a command similar to the following to associate a schedule when:

- Creating a volume:

```
maprcli volume create -name
<volName> -path
<mountPath> -tieringenable
true -tiername
<tierName> -offloadschedule
<scheduleID> -json
```

For the list of all other required and optional parameters, see [volume create](#) on page 2929.

- Editing the volume:

```
maprcli volume modify -name
<volName> -offloadschedule
<scheduleID> -json
```

For the list of all other required and optional parameters, see [volume modify](#) on page 3018.

REST

Send a request of type POST. For example, to associate a schedule when:

- Creating a volume:

```
curl -X POST 'https://<host>:8443/
rest/volume/create?
name=<volName>&path=<mountPath>&tie
ringenable=true&tiername=<tierName>
&offloadschedule=<scheduleID>' --us
er <username>:<password>
```

For the list of all other required and optional parameters, see [volume create](#) on page 2929.

- Editing the volume:

```
curl -k -X POST 'https://
<host>:8443/rest/volume/modify?
name=<volName>&offloadschedule=<sch
eduleID>' --user mapr:mapr
```

For the list of all other required and optional parameters, see [volume modify](#) on page 3018.

To disable automatic schedule-based offload of data, set the value for the `offloadschedule` parameter to 0.

Creating a Tiering-Enabled Volume**About this task**

You can create a tiering-enabled volume using the Control System, the CLI, and the REST API.

*Creating a Tiering-Enabled Volume Using the Control System***Procedure**

1. Go to **Data > Volumes** and click **Create Volume**.
The **Create New Volume** page displays.
2. Select the **Volume Type**, specify values for required/optional settings and auditing, and move the slider to **Yes** for **Data Tier** in the **Properties** tab.
For information on all other properties and settings, see [Creating a Volume](#) on page 1437.

NOTE: The source volume for a tiering-enabled mirror volume must also be tiering-enabled. You cannot set up a tiering-enabled mirror volume to mirror a volume that is not tiering-enabled.

3. Click **Create Volume** to create the tiering-enabled volume.

What to do next

You can proceed to [associate a tier, tiering rule, and/or schedule with the volume](#).

Creating a Tiering-Enabled Volume Using the CLI and REST API

About this task**CLI**

Run the following command to create a tiering-enabled volume:

```
$maprcli volume
create -name <volName> -path
<volmountpath> -tieringenable true
```

REST

Send a request of type POST. For example:

```
curl -X POST 'https://abc.sj.us:8443/
rest/volume/create?
name=<volName>&path=<volmountpath>&tie
ringenable=true' --user
<username>:<password>
```

For more information, see [volume create](#) on page 2929.

Associating a Tier Tiering Rule with a Volume**About this task**

You can associate a tier tiering rule with a new volume or with an already tiering-enabled volume using the Control System, CLI, and the REST API.

Associating a Tier Tiering Rule with a Volume Using the Control System

Procedure

- Perform the steps in the following topics to associate a tier, tiering rule, and/or schedule with:
 - [A new volume](#)
 - [A tiering-enabled volume](#)

*Associating a Tier Tiering Rule with a Volume Using the CLI***Procedure**

- Run the following command to associate a tier tiering rule with:
 - A new volume:

```
$maprcli volume create -name <vol_name> -path
<vol_mount_path> -tieringenable true -tiername <tier_name> -tieringrule
<rule_name>
```

For more information, see [volume create](#) on page 2929.

- An already tiering-enabled volume:

```
$maprcli volume modify -name <vol_name> -tiername
<tier_name> -tieringrule <rule_name>
```

For more information, see [volume modify](#) on page 3018.

NOTE: You cannot change the tier type or the tier for a volume after it is set.

*Associating a Tier Tiering Rule with a Volume Using the REST API***Procedure**

- Send a request of type POST to associate a tier tiering rule with:
 - A new volume. For example:

```
curl -X POST 'https://<host>:8443/rest/volume/create?
name=<vol_name>&path=<vol_mount_path>&tieringenable=true&tiername=<tier_
name>&tieringrule=<rule_name>' --user <username>:<password>
```

For more information, see [volume create](#) on page 2929.

- An already tiering-enabled volume. For example:

```
curl -X POST 'https://<host>:8443/rest/volume/modify?
name=<vol_name>&tiername=<tier_name>&tieringrule=<rule_name>' --user
<username>:<password>
```

For more information, see [volume modify](#) on page 3018.

NOTE: Volume's data tiering properties like tiername, ectopology, ecscheme, etc. cannot be modified after they are set.

Determining if a Volume is Enabled for Tiering**About this task**

You can determine if a volume is enabled for tiering and if rules, schedules, and/or settings for recalled data are associated with the volume using the Control System and the CLI.

*Determining if a Volume is Enabled for Tiering Using the Control System***Procedure**

- Log in to the Control System and click **Data > Volumes**.

In the list of volumes displayed in the **Volumes** pane, the **Data Tiering** column contains the value **Enabled** for a volume if the volume is enabled for tiering. If you do not see the column, you can see the column by [selecting the columns](#) to display in the Control System.

*Determining if a Volume is Enabled for Tiering Using the CLI***Procedure**

- Run one of the following commands to determine if a volume is enabled for tiering:

- `maprcli volume list -json`

- `maprcli volume info -name <volName> -json`

The output, if the volume is tiering-enabled (and has associated settings), should look similar to the following:

```
{
  "timestamp":1533959507772,
  "timeofday":"2018-08-10 08:51:47.772 GMT-0700 PM",
  "status":"OK",
  "total":1,
  "data":[
    {
      "acl":{
        "Principal":"User root",
        "Allowed actions":"[dump, restore, m, a,
d, fc]"
      },
      ...
      ...
      "tierenable":"true",
      "tierid":"169211273",
      "tierruleid":"2",
      "tieroffloadscheduleid":"6",
      "tierencryption":"false",
      "tierrecallexpirytime":"1",
      "tiercompactionscheduleid":"4",
      "tiercompactionoverheadthresh":"30",
      "gateway":"10.10.108.120:8660",
      "cvtotallused":0
    }
  ]
}
```

Offloading a Volume to a Tier

Explains how to offload a volume to a tier using either the Control System, the CLI, or the REST API.

About this task

At the volume level, data can be offloaded automatically by creating and associating a schedule with the tiering enabled volume or manually by triggering the offload operation. See [Data Offload and Purge](#) on page 580 for more information. The following sections describe how to set up an automatic offload of data

and how to trigger a one-time manual offload data at the volume level using either the Control System, the CLI, or the REST API.

NOTE: For a tiered volume, there can be only one running job at any given time. For example, suppose another job is running on the tiered volume, if you trigger an offload operation, the offload operation will fail.

To offload volume data, you must have one of the following permissions:

- Cluster level fc permissions
- Volume level fc permissions
- Volume modify permissions

NOTE: You can also offload individual files in a tiering-enabled volume to the associated tier. See [Offloading a File to a Tier Using the CLI and REST API](#) on page 1602 for more information.

IMPORTANT: EC volumes are automatically offloaded once they crossed the size of `autooffloadthresholdgb` even if they are not using the Automatic scheduler. The default size is 1024 GB (1 TB). You can modify this size as specified in [Offloading a Volume to a Tier](#) on page 1515.

Setting up Automatic Offload of Data Using the Control System

Procedure

1. Create a tier.
See [Creating a Cold Tier Using the Control System](#) on page 1548 or [Creating a Warm Tier Using the Control System](#) on page 1548 for more information.
2. Create a storage policy to associate with the volume.
See [Creating a Storage Tier Policy Using the Control System](#) on page 1564 for more information.
3. Create an offload schedule.
See [Specifying a Schedule for Offloading Data](#) on page 1510 for more information.
4. Create a tiering enabled volume and associate the tier, the storage policy, and schedule with the volume.
See [Creating a Tiering-Enabled Volume Using the Control System](#) on page 1513 for more information.

Triggering an Offload of all Data in a Volume to a Tier Using the Control System

Procedure

1. Log in to the Control System and click **Data > Volumes**.

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Select the tiered volumes to offload from the list of volumes in the **Volumes** pane.
Selecting a volume makes the **Actions** drop-down menu available.
3. Click **Offload Data** from the **Actions** drop-down menu to display the **Offload Volume Data** confirmation window.
4. Review the list of volumes to offload and click **Offload**.

Results

If the offload fails, CLDB retries the operation after some time. See [Retrying Failed Operation](#) on page 1521 for more information.

Setting up Automatic Offload of Data Using the CLI and REST API

About this task

To automatically offload data:

Procedure

1. Create a tier, a rule that contains the criteria for offloading data to the tier, and a schedule to automatically offload data to the tier.

For example:

CLI

```
/opt/mapr/bin/maprccli tier
create -name <tier_name> -type
ectier
/opt/mapr/bin/maprccli tier
create -name <tier_name> -type
cold -url <tier_url> -credential
<credentials>.txt -json
/opt/mapr/bin/maprccli tier rule
create -name <rule_name> -expr
<expressions>
/opt/mapr/bin/maprccli schedule
create -schedule <JSON>
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/create?
name=<tier_name>&type=ectier' --user
mapr:mapr
curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/create?
name=<tier_name>&type=cold&url=<tier
_url>&credential=<credential_str>'
--user mapr:mapr
curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/rule/
create?
name=<rule_name>&expr=<expressions>'
--user mapr:mapr
curl -k -X POST 'https://
abc.sj.us:8443/rest/schedule/create?
schedule=<JSON>' --user mapr:mapr
```

For more information, see [Managing Tiers](#) on page 1545 and [Managing Storage Policies](#) on page 1562.

2. Create a tiering-enabled volume and associate the tier, rule, and schedule (that you created in step 1) with the volume.

For example, to create a volume and enable it for:

- Warm tier:

CLI

```
/opt/mapr/bin/maprccli volume
create -name <vol_name> -path
<vol_mount_path> -tieringenable
```

REST

```
true -tiername
<tier_name> -ecscheme
<coding_scheme> -ectopology
<ec_vol_topo> -tieringrule
<rule_name> -offloadschedule
<schedule_ID>
```

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=<vol_name>&path=<vol_mount_pat
h>&tieringenable=true&tiername=<tie
r_name>&ecscheme=<coding_scheme>&ec
topology=<ec_vol_topo>&tieringrule=
<rule_name>&offloadschedule=<schedu
le_ID>' --user mapr:mapr
```

- Cold tier:

CLI

```
/opt/mapr/bin/maprcli volume
create -name <vol_name> -path
<vol_mount_path> -tieringenable
true -tiername
<tier_name> -tieringrule
<rule_name> -offloadschedule
<schedule_ID> -recallexpirytime
2 -json
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=<vol_name>&path=<vol_mount_pat
h>&tieringenable=true&tiername=<tie
r_name>&tieringrule=<rule_name>&off
loadschedule=<schedule_ID>&recallex
pirytime=2' --user mapr:mapr
```

You can also specify the maximum amount of data (in GB) to offload automatically for warm-tier volumes using the `autooffloadthresholdgb` parameter. For more information, see [Working with Tiered Volumes](#) on page 1504.

*Triggering an Offload of all Data in a Volume to a Tier Using the CLI and REST API***About this task****CLI**

Run the following command to manually trigger an offload of all data in the volume:

```
maprcli volume offload -name
<volume-name>
```

If you run the command with the `ignorerule` option value set to `true`, rules for the volume where the data resides is ignored and data is offloaded immediately. If the `ignorerule` option value is not specified or is set to `false` (default), data is offloaded based on the rules associated with the volume where the data resides.

REST

Submit a request of type POST. For example:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/offload?
name=sampleVol' --user mapr:mapr
{"timestamp":1519947659597,"timeofday"
:"2018-03-01 03:40:59.597 GMT-0800
PM","status":"OK","total":0,"data":
[],"messages":["Successfully started
offload."]}
```

For more information, see [volume offload](#) on page 3041.

Results

If the offload fails, CLDB retries the operation after some time. See [Retrying Failed Operation](#) on page 1521 for more information.

Recalling a Volume to file system

Explains how to recall offloaded data to the file system.

About this task

When you:

- Read data offloaded to a remote target (or cold tier), data is automatically recalled to the file system to allow the read to succeed.
- Modify data offloaded to an erasure coded volume (or warm tier) or a remote target (or cold tier), data is automatically recalled to the file system to allow the write to succeed.

The recalled data is automatically:

- Purged based on the expiration time period set at the volume level for recalled data if there are no changes (for example, read operation).
- Offloaded based on the rule and the expiration time period set at the volume level for recalled data if there are changes (for example, overwrite operation).

See [Data Reads, Writes, and Recalls](#) on page 587 for more information. If the recall fails, CLDB retries the operation after some time. See [Retrying Failed Operation](#) on page 1521 for more information.

You can manually recall all data in a volume using the Control System, CLI, or the REST API.

NOTE: For a tiered volume, there can be only one running job at any given time. If you trigger a recall operation when another job is running on the tiered volume, the recall operation will fail.

You can also recall individual files from the tier. See [Recalling a File to file system Using the CLI and REST API](#) on page 1602 for more information.

Recalling Offloaded Volume Using the Control System

Procedure

1. Log in to the Control System and click **Data > Volumes**.

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Select the tiered volumes to recall from the list of volumes in the **Volumes** pane.
Selecting a volume makes the **Actions** drop-down menu available.

3. Click **Recall Data** from the **Actions** drop-down menu to display the **Recall Tiered Data** confirmation window.
4. Review the list of volumes to recall and click **Recall Volumes**.
For more information, see [Recall of Tiered Data](#) on page 590.

Recalling Offloaded Volume Using the CLI and REST API

About this task

CLI

Run the following command to recall volume data:

```
/opt/mapr/bin/maprcli volume  
recall -name <volName>
```

REST API

Send a request of type POST to URL. For example:

```
curl -k -X  
POST 'https://abc.sj.us:8443/rest/  
volume/recall?name=volName' --user  
mapr:mapr
```

For more information, see [volume recall](#) on page 3043.

Viewing the List of Running Jobs

About this task

You can view the tiering jobs currently running for a volume using the CLI and REST API. For a tiered volume, at any given time, there can be only one running job.

Procedure

- Run the following command or send a request of type GET to retrieve the list of currently running tiering operations for a volume:

CLI

```
maprcli volume tierjobstatus -name  
<volName>
```

REST

```
curl -k -X  
GET 'https://<host>:8443/rest/volume/  
tierjobstatus?name=<volName>' --user  
mapr:mapr
```

For more information, see [volume tierjobstatus](#) on page 3056.

Terminating a Running Volume-Level Tiering Job

Describes how to terminate a volume-level tiering job using either the Control System or the CLI.

About this task

You can terminate an ongoing offload or recall of a volume using the Control System or the CLI.
Terminating a running:

- Offload operation does not prevent future offloads; if a schedule is associated with the volume, data that is still on the cluster is automatically offloaded based on the rules as per schedule. You can also manually offload data again at any time by running the [volume offload](#) on page 3041 command.

- Recall operation does not prevent future recalls; you can run the recall command again to recall the remaining data on the tier. Based on the expiry time set on the volume (associated with the recalled data), recalled data is offloaded if there are changes or purged if there are no changes. See [Recalling a Volume to file system](#) on page 1519 for more information.

You can check the status of an abort operation using the `volume tierjobstatus` on page 3056 command.

NOTE: If you terminate a job that CLDB was retrying after a prior failed attempt (FailureRetriable job), CLDB will stop trying to run the job again. For more information on FailureRetriable job, see [Retrying Failed Operation](#) on page 1521.

For information on terminating a file-level job, see [Terminating a Running File-Level Tiering Job](#) on page 1603 and [Running Tiering Commands when maprccli and hadoop Commands are not Available](#) on page 1604.

Terminating a Volume Offload or Recall Operation Using the Control System

Procedure

1. Log in to the Control System and click **Data > Volumes**.

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Select the tiered volumes to offload from the list of volumes in the **Volumes** pane. Selecting a volume makes the **Actions** drop-down menu available.
3. Click **Terminate Tiering Job** from the **Actions** drop-down menu to display the **Terminate Tiering Job** confirmation window.
4. Review the list of volumes and click **Terminate Job**.

Aborting Volume Offload or Recall Operation Using the CLI and REST API

About this task

CLI

Run the following command to abort a running offload or recall operation:

```
maprccli volume tierjobterminate -name <volName>
```

For more information, see [volume tierjobterminate](#) on page 3055.

REST API

Send a request of type POST. For example:

```
curl -X POST 'https://<host>:8443/rest/volume/tierjobterminate?name=<volName>' --user <username>:<password>
```

Retrying Failed Operation

About this task

Volume-level

If an offload, recall, or abort operation for a volume fails, the [volume tierjobstatus](#) on page 3056 command shows one of the following statuses:

FailureFatal	Indicates failure is fatal and CLDB cannot retry the operation again.
FailureRetriable	Indicates failure to offload; however, CLDB will try again if the job is not manually restarted again or aborted.

CLDB tries the operation again (up to 5 times by default) after a specific wait time (of 30 minutes by default) for the following errors:

- EAGAIN
- ETIMEDOUT
- ENETUNREACH
- ENETDOWN
- ECONNRESET

The RetryCount field value in the [volume tierjobstatus](#) on page 3056 command output shows the number of times CLDB has retried so far. For example:

```
# maprcli volume tierjobstatus -name testvol -json
{
  "timestamp":1503308792266,
  "timeofday":"2017-08-21 09:46:32.266 GMT+0000",
  "status":"OK",
  "total":1,
  "data":[
    {
      "offload":{
        "state":"FailureRetriable,
RetryCount: 5",
        "startTime":"2017-08-21 09:07:17.506 GMT+0000",
        "endTime":"2017-08-21 09:08:49.799 GMT+0000",
        "gateway":"10.10.102.68:8660"
      }
    }
  ]
}
```

File-level

If the offload or recall operation for an individual file fails, the [file tierstatus](#) on page 2509 or [hadoop mfs](#) on page 7489 command returns one of the following:

Code	Message	Description
0	HAS_LOCAL_DATA	Indicates that the file is not yet fully offloaded.
1	NO_LOCAL_DATA	Indicates that the file was completely offloaded.
2	OP_FAIL	Indicates that the operation to retrieve the status failed.
3	INVALID_FILE	Indicates that the file does not exist.
4	FILE_NOT_TIERED	Indicates that the file is not in a tiered volume.
5	FILE_EMPTY	Indicates that the file specified for offload is an empty file.
6	NO_GATEWAY	Indicates that no MAST Gateways are available for offload operation.
7	OP_TIMEOUT	Indicates that there was no response from the MAST Gateway (maybe as a result of an error) during the offload or recall operation.
8	FTOS_SUCCESS	Indicates that the file was successfully offloaded or recalled.
9	FTOS_ABORTED	Indicates that the file offload or recall operation was aborted.
10	FTOS_ABORT_IN_PROGRESS	Indicates that the file offload or recall job is being aborted.
11	FTOS_TRANSFER_IN_PROGRESS	Indicates that the file offload is in progress.

Code	Message	Description
12	FTOS_REQ_QU EUED	Indicates that the file offload is scheduled, but has not yet started.
13	FTOS_JOB_NO T_AVAILABLE	Indicates that the job ID specified with the tierjobstatus command is not available.

When a file-level offload or recall operation fails, CLDB **does not** retry the operation. For failed file-level:

- Offload operation, you can run the command to retry the operation. For more information, see [Offloading a File to a Tier Using the CLI and REST API](#) on page 1602. Alternatively, if the volume that the file is associated with has a data offload schedule, the file data is automatically offloaded based on the rules associated with the volume.
- Recall or abort operation, you can run the command again to retry the operation if the error returned is not EIO.

You can configure the number of times CLDB retries and the interval between retries using the CLI.

Configuring the Number of Retries

Procedure

- Set the value for the `cldb.gateway.retry.count` parameter, whose default value is 5, to configure the number of times that CLDB tries again. For example, to configure CLDB to retry to offload, recall, or abort at least 10 times, run the following command:

```
# maprcli config save -values {"cldb.gateway.retry.count":"10"}
```

Configuring the Interval Between Retries

Procedure

- Set the value for the `cldb.gateway.retry.waittime.seconds` parameter, whose default value is 1800 seconds (30 minutes), to configure the amount of time CLDB waits between retries. For example, to configure CLDB to wait for up to 4 hours (14400 seconds), run the following command:

```
# maprcli config save -values {"cldb.gateway.retry.waittime.seconds":"14400"}
```

Running the Compactor Using the CLI and REST API

About this task

You can trigger the compactor using the CLI and REST API to purge recalled data on the Data Fabric cluster or to purge stale data on the tier. See [Data Compaction](#) on page 592 for more information about data compaction.

*Running the Compactor to Purge Recalled Data on the Data Fabric Cluster***About this task****CLI**

Run the following command to trigger the compactor and purge data whether or not the expiry time for recalled data has been reached:

```
maprcli volume compact -name
<volName> -forcerecallexpiry true
```

REST

Send a request of type POST. For example:

```
curl -X POST --user <username>
'https://<host>:8443/rest/volume/
compact?
name=<volName>&forcerecallexpiry=true'
```

For more information, see [volume compact](#) on page 2924.

*Running the Compactor to Purge Stale Data on the Tier***About this task****CLI**

Run the following command to trigger the compactor:

```
maprcli volume compact -name <volName>
```

REST

Send a request of type POST.

```
curl -X POST --user
<username> 'https://<host>:8443/rest/
volume/compact?name=<volName>'
```

When you trigger the compactor, the compactor purges stale data from the tier and also recalled data on the Data Fabric cluster if the expiry time for recalled data has been reached. For more information, see [volume compact](#) on page 2924.

Retrieving the Status of a Volume-level Tiering Operation**About this task**

You can check the status of an active volume offload, completed offload, aborted offload, and recall operations using the Control System, the CLI, and the REST API. For information on file level tiering job, see [Retrieving Status of File-level Tiering Operation and File Data](#) on page 1605.

*Retrieving Status of Volume-level Operation Using the Control System***Procedure**

- Log in to the Control System and click **Data > Volumes**.
The **Volumes** pane in the page displays the following for tiered volumes:
 - **Job** — The currently running or last completed tiering job for the volume.
 - **State** — The status of the tiering job.
 - **Progress** — The completion percentage of the tiering job.

*Retrieving Status of Volume-level Operation Using the CLI and REST API***About this task****CLI**

Run the following command to check the status of an active or completed offload, abort, and/or recall operation:

```
maprcli volume tierjobstatus -name
<volume_name> -json
```

NOTE: You must have full control (fc) permissions either at the cluster or at the volume level to run this command. To determine the status of a compaction operation, specify the verbose option with the tierjobstatus command. For example:

```
maprcli volume
tierjobstatus -name
<volume_name> -verbose true -json
```

REST

Send a request of type GET.

```
curl -X GET 'https://
<host>:8443/rest/volume/tierjobstatus?
name=<volume_name>' --user
<username>:<password>
```

See [Statuses](#) on page 3057 for more information.

Retrieving Tiering Statistics Using guts

Explains how to use the guts utility to retrieve tiering statistics.

You can run the [/opt/mapr/bin/guts](#) utility to get granular information on ongoing offloads and recalls including:

- The number of objects that are offloaded to and recalled from the tier
- The number of reads and writes on HPE Data Fabric Database
- The number of reads and writes on file system

Syntax

```
/opt/mapr/bin/guts <argument>:<options>
```

Arguments

Argument	Description
mastgateway	Refers to operations on the MAST Gateway node. See Usage on page 1527 for information on the syntax for running the guts command with this argument.
fstier	Refers to operations on file system node. See Usage on page 1527 for information on the syntax for running the guts command with this argument.

Options

Option	Description
all	Statistics for all operations.
db	Statistics for MAST Gateway operations currently running on HPE Data Fabric Database.
mfstats	Statistics for MAST Gateway operations on file system.
none	Specifies the column(s) to exclude from the output.
tier	Statistics for MAST Gateway operations on the storage tier.

Usage

MAST Gateway Node

```
/opt/mapr/bin/guts mastgateway:all
/opt/mapr/bin/guts mastgateway:db
/opt/mapr/bin/guts mastgateway:tier
/opt/mapr/bin/guts mastgateway:mfstats
/opt/mapr/bin/guts mastgateway:none
```

file system Node

```
/opt/mapr/bin/guts fstier:all
/opt/mapr/bin/guts fstier:none
```

NOTE: These commands might show statistics for several other fields. To skip, use none with the components whose fields you do not wish to retrieve. For example, to retrieve statistics for only the mastgateway tier, run the following command:

```
/opt/mapr/bin/guts allocator:none btree:none cache:none cleaner:none
client:none cpu:none db:none dbrepl:none disk:none fs:none fstier:none
gateway:none io:none kv:none log:none mastgateway:tier net:none
nfs:none rpc:none ssd:none streams:none time:none vcd:none
```

Output

mastgateway:tier

objP	Number of objects (whose maximum size is 8MB for cold-tier or whose size is computed based on the erasure coding scheme for warm-tier) that were offloaded to the storage tier.
objG	Number of objects (whose size is up to 1 MB for cold-tier and whose size is computed based on the erasure coding scheme for warm-tier) that were recalled from the storage tier.
objD	Number of deletions on the tier.

objPM	Amount of data (in MB) offloaded per second to the storage tier.
objGM	Amount of data (in MB) recalled per second from the storage tier.

mastgateway:db

tdbP	Number of <i>puts</i> on HPE Data Fabric Database tables.
tdbG	Number of <i>gets</i> on HPE Data Fabric Database tables.
tdbD	Number of <i>deletes</i> on HPE Data Fabric Database tables.

mastgateway:mfsops

moR	Number of <i>read</i> requests from client to the MAST Gateway service to read from cache volumes.
mp	Number of file system <i>purge</i> requests sent by the MAST Gateway service.
mrw	Number of file system <i>reads</i> from the MAST Gateway service to perform modify/write operation.
moRM	Amount of file system <i>reads</i> (in MB) sent by the MAST Gateway service to read offloaded data.
mrwM	Amount of <i>recall writes</i> (in MB) sent by the MAST Gateway service.

fstier:all

tp	Number of blocks (of 64KB) <i>purged</i> during an offload operation.
trw	Number of blocks (of 64KB) <i>written</i> during recall of offloaded data.
trr	Number of blocks (of 64KB) <i>read</i> during read of offloaded data.
twr	Number of blocks (of 64KB) <i>recalled</i> for partial overwrites.

Related reference

[guts](#) on page 3257

guts is a tool to measure/analyse performance. In the default mode, it prints one line every second, and counts the number of operations or bytes-processed in one second intervals. guts is an internal utility, and is subject to change without notice.

[cldbguts](#) on page 3218

Monitors the activity of the Container Location Database (CLDB). This utility prints information about the CLDB service that is running on the node from which you run the utility.

Moving back end Volume from the Command Line

This section contains information on migrating the following volumes to a different topology:

- Metadata volume, which stores the DB tables for the metadata associated with the tier.
- Erasure-coded volume, which stores the erasure-coded data.

Moving Metadata Volume to Another Topology

By default, the volume, which stores the DB tables for the metadata associated with the tier, is created in `/var/mapr/tier/mapr.internal.tier.<volName>` and is in the /data topology. However, you can move the metadata volume to another topology using the [volume move](#) on page 3039 command. For example:

CLI

```
/opt/mapr/bin/maprcli
volume move -name
<metadataVolName> -topology <newTopo>
```

REST

```
curl -k -X POST 'https://<host>:8443/
volume/move?
name=<metadataVolName>&topology=<newTo
po>' --user mapr:mapr
```

Moving Erasure-Coded Volume to Another Topology

The erasure-coded volume is by default created in the same topology as the front-end volume. You can specify a different topology for the erasure-coded volume when creating a front-end volume. You can also move the erasure coded volume to a different topology using the [volume move](#) on page 3039 command. For example:

CLI

```
/opt/mapr/bin/maprcli volume
move -name <volName> -ectopology
<newTopo>
```

REST

```
curl -k -X POST 'https://<host>:8443/
volume/move?
name=<volName>&ectopology=<newTopo>'
--user mapr:mapr
```

Here, the name parameter takes the name of the front-end volume and the ectopology parameter takes the topology to which to move the erasure-coded volume associated with the front-end volume. For more information, see [volume move](#) on page 3039.

Inline Erasure Coding

Explains inline erasure coding.

Inline erasure coding is an erasure coding mechanism to write data to the backup volume at the earliest possible time, rather than waiting for scheduled or manual offloads to happen on the volume. Inline erasure coding reduces the amount of storage that needs to be provisioned for front-end volumes. Inline erasure coding is referred to as instant tiering.

Inline erasure coding is a process where the data on the tiered front-end volume is continuously erasure-coded and written to the backend erasure-coded (EC) volume.

Data Fabric supports inline erasure coding for S3 bucket volumes only.

Objects ingested in s3 bucket are stored in a S3 bucket volume configured for erasure coding. Subsequently, data from the S3 bucket volume is erasure coded and stored in the corresponding EC back-end volume, thereby freeing up space from S3 bucket volume.

Inline erasure coding can be configured at two levels:

- Cluster level. When you enable inline erasure coding at the cluster/fabric level, inline erasure coding is enabled for every bucket created afterward. If inline erasure feature is enabled and `ec_scheme storage_class label` is attached to the S3 account, all the buckets created tagged to the corresponding S3 account are created as inline EC S3 buckets.
- cluster level

See [Non-inline Erasure Coding Vs Inline Erasure Coding](#) on page 1530 for a comparison between erasure coding and inline

Non-inline Erasure Coding Vs Inline Erasure Coding

Comparison between non-inline erasure coding/scheduled tiering and inline erasure coding/instant tiering.

Non-inline erasure coding refers to the erasure coding that exists pre-8.1. Non-inline erasure coding is called scheduled tiering.

Inline erasure coding is called instant tiering.

The following table compares non-inline erasure coding and inline erasure coding.

Table

Behavior/operation	Non-inline erasure coding	Inline erasure coding
Data replication	3x until offloaded	~1.5x because of continuous offloads
Data Offload to backend volume	scheduled or manually initiated	automatic and continuously running
Availability from Data Fabric version	6.2	8.1
Advantages	Control over offload scheduling	Efficient storage utilization
Disadvantages	Requires more storage for front end volume until offloaded.	Marginal higher resource consumption
Support for S3 buckets (object store)	Yes	Yes
Support for files	Yes	No
Task status as seen on command line	The task state, status, progress, offload start, offload end times	The task state is always running, last inline erasure coding (IEC) offload attempt, last IEC success timestamps

Using Volume Links for Read and Write Operations

When you mirror a volume, read requests to the source volume can be served by any of its mirrors on the same cluster via a volume link of type `mirror`. A volume link is similar to a normal volume mount point, except that you can specify whether it points to the source volume or its mirrors.

- To write to (and read from) the source volume, mount the source volume normally.

As long as the source volume is mounted below a non-mirrored volume, you can read and write to the volume normally via its direct mount path. You can also use a volume link of type `writable` to write directly to the source volume regardless of its mount point.

- To read from the mirrors, use the `volume link create` command to make a volume link (of type `mirror`) to the source volume.

Any read requests from the volume link are distributed among the volume's mirrors. Since the volume link provides access to the mirror volumes, you do not need to mount the mirror volumes.

Managing Snapshots

This section provide information about managing snapshots.

A snapshot is a read-only image of a volume at a specific point in time. On clusters with an Enterprise Edition or higher license, you can create a snapshot manually or automate the process with a schedule. Snapshots are useful any time you need to be able to roll back to a known good data set at a specific point in time. For example, before performing a risky operation on a volume, you can create a snapshot to enable rollback capability for the entire volume.

A snapshot takes no time to create, and initially uses no disk space, because it stores only the incremental changes needed to roll the volume back to the state at the time the snapshot was created. The storage used by a volume's snapshots does not count against the volume's quota. When you view the list of volumes on your cluster in the Control System, the value of the Snap Size column is the disk space used by all of the snapshots for that volume.

NOTE: Snapshot volumes inherit the auditing configurations of their original read-write volumes. For details about auditing, see [Auditing](#).

You can perform the following tasks using the Control System and the CLI.

Creating Volume Snapshots

Describes how to create snapshots of volumes using the Control System and the CLI.

About this task

You can create a snapshot manually using the Control System and the CLI, or use a schedule to automate snapshot creation.

NOTE: The maximum number of snapshots that you can create for each volume is 4092. Exceeding this limit raises the snapshot failure alarm with an appropriate entry in the CLDB logs.

Creating Snapshots of Multiple Volumes Using the Control System

About this task

To create snapshots of multiple (standard and/or mirror) volumes manually:

Procedure

1. Log in to the Control System and go to the **Summary** tab in the **Data > Volumes** page.

NOTE: When running on a Kubernetes cluster, the **Summary** tab is on the **Volumes** page.

2. Select the volume(s) for which you need to create the snapshots.
3. Click **Snapshot Volume** from the **Actions** drop-down menu.
The **Snapshot Volume(s)** confirmation dialog displays.

4. Verify the list of volumes and enter a unique name for the snapshot in the **New Snapshot Name** field.
5. Click **Snapshot Volumes**.

Creating a Snapshot of a Volume Using the Control System

About this task

You can create a snapshot manually or use a schedule to automate snapshot creation. To create a snapshot of a volume manually:

Procedure

1. Log in to the Control System and go to the **Snapshots** tab in the [volume information page](#).
2. Click **Create Snapshot** to display the **Create Snapshot** window.
3. Enter a unique name for the snapshot in the **New Snapshot Name** field.
4. Click **Create Snapshot** to create a snapshot of the volume.
By default, manually created snapshots do not have an expiration date.

Creating Volume Snapshots Using the CLI or REST API

About this task

The basic command to create a snapshot is:

```
maprcli volume snapshot create -snapshotname <snapshot> -volume <volume>
```

For complete reference information, see [volume snapshot create](#) on page 3047.

Viewing the list of Snapshots

Describes how to view the list of snapshots that are present on a cluster, using the Control System or the CLI.

About this task

You can view the snapshots on the cluster using the Control System or the CLI.

Viewing All the Snapshots Using the Control System

Procedure

- The **Snapshots** tab under the **Data > Volumes** page displays all the snapshots on the cluster.

NOTE: When running on a Kubernetes cluster, the **Snapshots** tab is under the **Volumes** page that is under the **Volumes** menu.

For each snapshot, you can view the following:

Column Name	Column Description
Snapshot Name	The name of the snapshot.
Volume	The volume with which the snapshot is associated.
Created On	The date when the snapshot was created.
Expires On	The date when the snapshot expires.
Reclaim Size	Disk space (in MB) used/owned by the snapshot

You can select one or more snapshots to:

- [Preserve](#)
- [Remove](#)

Viewing the Snapshots Associated with a Volume Using the Control System

Procedure

- Log in to the Control System and go to the **Snapshots** tab in the [volume information page](#).
The list of snapshots associated with the volume displays in this tab. For each snapshot, the pane displays the following:

Column Name	Column Description
Snapshot Name	The name of the snapshot.
Volume	The volume with which the snapshot is associated.
Created On	The date when the snapshot was created.
Expires On	The date when the snapshot expires.
Reclaim Size	Disk space (in MB) used/owned by the snapshot

You can [create a snapshot](#) of the volume or select one or more snapshots to:

- [Preserve](#)
- [Remove](#)

Viewing Snapshots Using the CLI or REST API

About this task

The basic command to retrieve a list of snapshots is:

```
maprcli volume snapshot list
```

For complete reference information, see [volume snapshot list](#) on page 3049.

Filtering the List of Snapshots

Describes how to filter the list of snapshots using the Control System or the CLI.

About this task

The filter in the **Snapshots** tab on the **Data > Volumes** page lets you build search expressions to provide sophisticated filtering capabilities for locating specific data on views that display a large number of volumes. Expressions are implicitly connected by the AND operator.

NOTE: When running on a Kubernetes cluster, the filter is present in the **Snapshots** tab on the **Volumes** page under the **Volumes** menu.

Filtering the List of Snapshots Using the Control System

Procedure

1. Log in to the Control System and click **Data > Volumes > Snapshots** to filter list of snapshots in the **Snapshots** page.

NOTE: When running on a Kubernetes cluster, click **Volumes > Snapshots** to filter list of snapshots in the **Snapshots** page.

2. Click and select one of the following from the **Add Filter** drop down menu:
 - Snapshot Name — to filter the list by snapshot name
 - Volume — to filter the list by volume name
 - Created on — to filter the list by snapshot creation date range
 - Expires on — to filter the list by snapshot expiration date range
3. Specify the value in the drop-down field for the selected filter (on which to filter the list of snapshots) and click **Filter**.

As you make selections and specify the filtering criteria, the pane displays only the snapshots that match the specified filtering criteria.

4. Click:
 - **Add Filter** to add another filtering criteria.
 - to remove a filtering criteria.
 - to clear all filter settings.

Filtering the List of Snapshots Using the CLI and REST API

About this task

CLI

The [volume snapshot list](#) on page 3049 command can be used with the `-filter` option, which let you specify large numbers of snapshots by matching specified values in specified fields rather than by typing each name explicitly. For example, you can display all snapshots associated with the volume `test` as follows:

```
maprcli volume snapshot list -filter
[vn=="test"] -json
```

REST

Send a request of type GET. For example, to display all snapshots associated with the volume `test`, send a request similar to the following:

```
curl -k -X GET 'https://
<hostname>:8443/rest/volume/snapshot/
list?
filter=%5Bvn%3D%3D%22test%22%5D' --use
r <username>:<pwd>
```

For more information, see [volume snapshot list](#) on page 3049.

Viewing the Contents of a Snapshot from the Command Line

Describes how to view the contents of the `.snapshot` directory from the CLI.

At the top level of each volume is a directory named `.snapshot` containing all the snapshots for the volume. You can view the directory with `hadoop fs -ls` commands or by mounting the cluster with NFS. To prevent recursion problems, `ls` and `hadoop fs -ls` do not show the `.snapshot` directory when you list the contents of the top-level volume directory. You must navigate explicitly to the `.snapshot` directory to view and list the snapshots for the volume.

Example:

```
hadoop fs -ls /myvol/.snapshot
Found 1 items
drwxrwxrwx - root root          1 2011-06-01 09:57 /myvol/.snapshot/
2011-06-01.09-57-49
```

In the preceding example, `/myvol` is the mount point of the volume for which the snapshot named `2011-06-01.09-57-49` was created and stored in the `.snapshot` directory.

Preserving one or more Snapshots

Describes how to preserve a snapshot using the `volume snapshot preserve` command, or using the Control System.

Preserving Snapshots Using the Control System

About this task

You can preserve a snapshot to prevent it from expiring. To preserve one or more snapshots, in the **Snapshots** tab (under **Data > Volumes**):

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

Procedure

1. Select the snapshot(s) you want to preserve.
2. Click **Preserve Snapshot** to preserve the snapshot(s).
The **Preserve Snapshot(s)** confirmation dialog displays.
3. Verify the list of snapshots to preserve and click **Preserve Snapshots**.
The **Expires On** column for the selected snapshots will show **No Expiration**. You *cannot* set an expiration date for a preserved snapshot; instead, if necessary, remove the preserved snapshot.

Preserving Snapshots Associated with a Volume Using the Control System

About this task

You can preserve a snapshot to prevent it from expiring. To preserve one or more snapshots (and prevent them from expiring) associated with a volume:

Procedure

1. Log in to the Control System and go to the **Snapshots** tab in the [volume information page](#).
The list of snapshots associated with the volume displays.
2. Select the snapshots to preserve and click **Preserve Snapshot**.
The **Preserve Snapshot(s)** confirmation dialog displays.

3. Verify the list of snapshots to preserve and click **Preserve Snapshots**.

The **Expires On** column for the selected snapshots will show **No Expiration**. You *cannot* set an expiration date for a preserved snapshot; instead, if necessary, remove the preserved snapshot.

Preserving Snapshots Using the CLI or the REST API

About this task

The basic command to preserve the snapshots is:

```
maprcli volume snapshot preserve
```

For complete reference information, see [volume snapshot preserve](#) on page 3051.

Removing one or more Snapshots

Explains how to remove a snapshot using the [volume snapshot remove](#) command or using the Control System.

About this task

Each snapshot has a date and time at which it expires. You can remove a snapshot manually before its expiration, or you can [preserve](#) a snapshot to prevent it from expiring.

Removing Snapshots Using the Control System

About this task

To remove one or more snapshots, in the **Snapshots** tab under **Data > Volumes**:

NOTE: The **Volumes** page is under the **Volumes** in the Kubernetes version of the Control System.

Procedure

1. Select the snapshots to remove.
2. Click **Remove Snapshot**.
The **Remove Snapshots** confirmation dialog displays.
3. Verify the list of snapshots to remove and click **Remove Snapshots**.
When you remove a snapshot, the snapshot is removed from the system and cannot be restored.

Removing Snapshots Associated with a Volume Using the Control System

About this task

To remove one or more snapshots associated with a volume:

Procedure

1. Log in to the Control System and go to the **Snapshots** tab in the [volume information page](#).
The list of snapshots associated with the volume displays.
2. Select the snapshots to remove and click **Remove Snapshot**.
The **Remove Snapshots** confirmation dialog displays.
3. Verify the list of snapshots to remove and click **Remove Snapshots**.
When you remove a snapshot, the snapshot is removed from the system and cannot be restored.

Removing Snapshots Using the CLI or REST API

About this task

The basic command to remove a snapshot is:

```
maprcli volume snapshot remove
```

For complete reference information, see [volume snapshot remove](#) on page 3053.

Restoring Volume Snapshots Using the Control System

Describes how to restore snapshots of volumes using the Control System.

About this task

You can restore snapshots using the Control System.

For an overview on the Snapshot Restore functionality, refer to [Restoring a Volume From a Snapshot](#) on page 593.

To restore a snapshot, using the CLI, use the [volume snapshot restore](#) on page 3071 command.

To check the progress of a snapshot restore operation, use the [volume snapshot restorestatus](#) on page 3073 command.

Restoring Snapshots Using the Control System

About this task

To restore either a single or multiple snapshots of a single or multiple (standard and/or mirror) volumes:

Procedure

1. Log in to the Control System and go to the **Snapshots** tab on the **Data > Volumes** page.

NOTE: When running on a Kubernetes cluster, the **Snapshots** tab is on the **Volumes** page under the **Volumes** menu .

2. Select a snapshot or multiple snapshots to restore.
3. Click **Restore Snapshot** from the menu.
4. Verify the list of snapshots, read through the information displayed, and click **Restore Snapshot**.

TIP: The Control System displays notifications that show the status of the Snapshot Restore operation.

Related concepts

[Restoring a Volume From a Snapshot](#) on page 593

Provides a synopsis of restoring a volume from a snapshot. Describes the implications, and the prerequisites.

Related reference

[volume snapshot restore](#) on page 3071

Restores a volume from a snapshot using the CLI.

[volume snapshot restorestatus](#) on page 3073

Displays the progress of the snapshot restore operation, in terms of percentage.

Copying From a Snapshot Using the CLI

Describes how to create a volume by copying data from a snapshot

 **NOTE:** A snapshot must be restored into a volume to access the database tables or streams contained in the snapshot. Copying of data from tables or streams contained in a snapshot with Linux commands is not supported.

Copying data from a snapshot involves a simple copy operation from the `.snapshot` directory to the destination, as in the following example. User input is marked in **bold**:

 **NOTE:** This example assumes that the file system is mounted on `/mapr` using FUSE as explained in [Mounting the Filesystem](#).

```
[user@host]$ maprcli volume snapshot create -snapshotname
uservolsnap -volume users
[user@host]$ maprcli volume snapshot list
snapshotid sharedSize volumename ownername cumulativeReclaimSizeMB
numSizeUpdates snapshotname enforcementMode ownedsize
sizeUpdateRequestedAt ownertype numSizeUpdatesDesired volumeid
creationtime volumepath volumeSnapshotAces

Managing User Disk Usage

The **User Disk Usage** tab in the **Data > Volumes** page displays information about disk usage by cluster users. You can perform the following tasks to manage disk quotas using the Control System and the CLI.

Viewing User Disk Usage Information

Explains how to view user disk usage information using either the Control System or the CLI.

Viewing User Disk Usage Information Using the Control System

About this task

To view information about disk usage by cluster users:

Procedure

- Log in to the Control System and go to the **User Disk Usage** tab under **Data > Volumes**.

 **NOTE:** The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

The disk usage information for all the users displays. For each user, the **Accountable Entities** pane displays the following:

Column Name	Column Description
Type	The type of accountable entity (AE) . Value can be User or Group.
Accountable Entity	The user or group responsible for the volume.
Disk Usage	The total disk space used by the user.
Volume Count	The number of volumes.
Hard Quota	The user's hard quota.
Advisory Quota	The user's advisory quota.
Email	The email address of the user.

Selecting the checkbox beside an accountable entity makes the **Edit Properties** button available. You can modify the quotas for the selected entities by clicking [Edit Properties](#). Alternatively, you can click on an entity or associated  to [modify](#) the email address and quotas for the entity.

Viewing User Disk Usage Information Using the CLI or REST API

About this task

The basic command to view user disk usage information is:

```
maprcli entity info -name <entity name> -type <type>
```

For complete reference information, see [entity info](#) on page 2478.

Set or Modify Quotas for Users and/or Groups

Explains how to set or modify quotas for one or more entities using either the Control System or the CLI.

Set or Modify Quotas for Multiple Users and/or Groups Using the Control System

About this task

To edit the quota, which limits the space used by all the volumes owned by a user or group, for one or more users, in the **User Disk Usage** tab under **Data > Volumes**:

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

Procedure

1. Select the users/groups from the list of users/groups in the **Accountable Entities** pane.
2. Click **Edit Properties**.
The **Edit Properties** dialog displays.
3. Verify the list of users/groups and modify or set the following for the users/groups:
 - a) Hard quota, which raises an alarm when the limit is reached and prevents further writes.
 - b) Advisory quota, which raises an alarm when the threshold is reached, but does not prevent further writes.

NOTE: Both, advisory and hard, quotas can be expressed in megabytes (MB), which is the default, gigabytes (GB), or terabytes (TB).

4. Click **Save Changes** for the changes to take effect.

Set or Modify Quotas for an Entity Using the Control System

About this task

To edit the quota, which limits the space used by all the volumes owned by a user or group, for a user, in the **User Disk Usage** tab under **Data > Volumes**:

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

Procedure

1. Click the user/group from the list of users/groups or the  associated with the user/group in the **Accountable Entities** pane to display the **Edit Properties** window.
2. Modify or set the following for the user or group:
 - a) Enter the email address of the user/group.
 - b) Hard quota, which raises an alarm when the limit is reached and prevents further writes.
 - c) Advisory quota, which raises an alarm when the threshold is reached, but does not prevent further writes.
The advisory quota must be less than the hard quota.

NOTE: Both, advisory and hard, quotas can be expressed in megabytes (MB), which is the default, gigabytes (GB), terabytes (TB), petabytes (PB), exabytes (EB), and zettabytes (ZB).

3. Click **Save Changes** for the changes to take effect.

Set or Modify Quotas for Users and/or Groups Using the CLI or the REST API

About this task

The basic command to set or modify quotas for multiple entities is:

```
maprcli entity modify
  -entities <entities>
  -advisoryquota <advisory quota>
  -quota <quota>
```

The basic command to set or modify quotas for an entity is:

```
maprcli entity modify
  -name <entityname>
  -type <type>
  -advisoryquota <advisory quota>
  -quota <quota>
```

For complete reference information, see [entity modify](#) on page 2481.

[accounting entity \(AE\)](#) on page 8498

[accountable entity \(AE\)](#) on page 8498

Managing Schedules

A schedule is a group of rules that specify recurring points in time at which certain actions are determined to occur. You can use schedules to automate the creation of snapshots and mirrors and the offload of

volume data to a storage tier; after you create a schedule, it appears as a choice in the scheduling menu when you are [creating](#) or [editing](#) a volume.

When you specify a *snapshot* schedule on a mirror volume, it specifies how often to take a snapshot of the mirror volume. This snapshot schedule is distinct from the snapshot schedule for the standard volume. A snapshot schedule for a promotable mirror volume has two purposes:

- It specifies how often to take a snapshot of the mirror volume for the purpose of preserving the state of the mirror before a subsequent mirror operation. This way, if corrupt data is copied from the source volume's snapshot into the mirror volume, the mirror contents can be rolled back to the snapshot.
- If the promotable mirror volume is promoted to a read-write volume, the snapshot schedule specified for the mirror is used for the promoted read-write volume. Once a mirror volume is promoted to a read-write volume, the mirror schedule is disabled.

A *mirror* schedule specifies how frequently the mirror volume is synchronized with the source volume. In case of a disaster (or any type of data loss on a read-write source volume), the data can be recovered from the mirror volume, but any data written to the source volume since the last successful mirror operation will not be on the mirror volume. Therefore, you should set the mirror schedule such that it meets your RPO (Recovery Point Objective).

A *tier offload* schedule specifies how frequently data in the volume on the cluster is offloaded to the tiered storage. The MAST Gateway uses this setting to automatically offload data to the storage tier.

Schedules require the Enterprise Edition license.

Viewing the List of Schedules

Explains how to view all the schedules using the Control System or the CLI.

Viewing the List of Schedules Using the Control System

About this task

To view all the schedules:

Procedure

Log in to the Control System and go to the **Schedules** tab under **Data > Volumes**.

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

The page displays all the schedules. For each schedule, the page displays the following:

Column Name	Column Description
Schedule Name	The name of the schedule.
ID	The schedule ID.
In Use	Checkmark (✓) indicates the schedule is currently being used.
Detail	The schedule details such as the recurring points in time when the associated actions occur and how long the data is preserved.

Selecting the checkbox associated with a schedule makes the **Remove Schedule** button available. You can:

- [Create](#) a new schedule by clicking **Create Schedule**
- [Remove](#) a schedule by selecting the checkbox beside the schedule (to remove) and then by clicking **Remove Schedule**

- [Edit](#) a schedule by clicking the schedule name

Retrieving the List of Schedules Using the CLI or REST API

About this task

The basic command to retrieve a list of schedules is:

```
maprcli schedule list
```

For complete reference information, see [schedule list](#) on page 2617.

Creating a Schedule

Explains how to create a schedule using the Control System or the CLI.

Creating a Schedule Using the Control System

About this task

A schedule is a group of rules that specify recurring points in time at which certain actions are determined to occur. You can use schedules to automate the creation of snapshots and mirrors. To create a new schedule:

Procedure

1. Log in to the Control System and go to the **Schedules** tab in the **Data > Volumes** page.

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Click **Create Schedule**.

The **Create Schedule** dialog displays.

3. Enter a name for the schedule in the **Schedule Name** text field.

4. Specify the schedule rules with the following components:

Frequency	Specify frequency (Once, Yearly, Monthly, Weekly, Daily, Hourly, Every X minutes).
Time	Specify the point of time within the specified frequency to perform the scheduled action. For example, if you selected Monthly from the first drop-down menu, select the day of the month from the second drop-down menu. Continue with each drop-down menu, proceeding to the right, to specify the time at which the scheduled action is to occur. NOTE: This is available only if the selected frequency is Once, Yearly, Monthly, Weekly, or Daily.
Retain for	Specify how long the data should be preserved. For example, if the schedule is attached to a volume for creating snapshots, the Retain for specifies how far after creation the snapshot expiration date is set.

If necessary, click **Add Another** to add another rule to the schedule or to remove a rule.

5. Click **Create Schedule** to create the schedule.

After the schedule is created, it appears as a choice in the scheduling menu when you are creating a new volume or editing a volume.

Creating a Schedule Using the CLI or REST API

About this task

The basic command to create a schedule is:

```
maprcli schedule create -schedule <JSON>
```

For complete reference information, see [schedule create](#) on page 2616.

Guidelines for Setting Mirror Schedules

Although Data Fabric allows mirroring frequencies up to once per minute, setting a schedule at this frequency is not practical nor advisable. When you choose the mirror schedule, consider the amount of data on the volume and the load on the cluster. Remember that the mirroring frequency must allow enough time to complete one mirror operation before the next scheduled mirror operation starts. In addition, if you have a cascaded mirror setup (where A mirrors to B which mirrors to C), you cannot set a mirror schedule for C that starts before B finishes mirroring from A.

 **WARNING:** In general, you should not set a mirror schedule for more often than every 30 minutes.

If you set a mirror schedule to start mirroring before the previous mirror operation finishes, you will see an error message similar to this:

```
WARN Alarms [pool-2-thread-1]: Alarm raised: VOLUME_ALARM_MIRROR_FAILURE;
Cluster: Cluster1; Volume: ; Message: Cannot start new scheduled mirror
because existing mirror is in progress
```

Modifying a Schedule

Explains how to modify a schedule using either the Control System or the CLI.

Modifying a Schedule Using the Control System

About this task

When you modify a schedule, the new set of rules replaces any existing rules for the schedule. To edit a schedule, in the **Schedules** tab under **Data > Volumes**:

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

Procedure

1. Click the schedule name of the schedule to edit.
The **Edit Schedule** dialog displays.
2. Modify the schedule as desired:
 - a) Change the schedule name in the **Schedule Name** field.
 - b) Add, modify, or remove rules in the **SCHEDULE RULE** section.
Here:

Frequency	Specifies the frequency (Once, Yearly, Monthly, Weekly, Daily, Hourly, Every X minutes).
Time	Specifies the point of time within the specified frequency to perform the scheduled action. This is available only if the selected frequency is Once, Yearly, Monthly, Weekly, or Daily.
Retain for	Specifies how long the data should be preserved.

To add another rule, click **Add Another** and to remove a rule, click .

3. Click **Save Changes** for the changes to take effect.

Modifying a Schedule Using the CLI or REST API

About this task

The basic command to modify a schedule is:

```
maprcli schedule modify -id <schedule ID> -rules <JSON>
```

For complete reference information, see [schedule modify](#) on page 2621.

Selecting an Existing Schedule to Associate with a Volume

Explains how to associate an existing schedule with a volume using the Control System, the CLI, or the REST API.

Selecting an Existing Schedule Using the Control System

Procedure

1. Log in to the Control System and go to **Summary** tab in the [volume details](#) page.
2. Click the  (associated with the type of schedule in the **Schedules** pane) to display the **Edit Schedules** window.
3. Review the name and detail of each schedule and select a schedule from the list.
4. Click **Save Changes** to associate the schedule with the volume.

Selecting an Existing Schedule Using the CLI and REST API

About this task

CLI

You can associate a schedule with a volume using the `schedule` parameter when creating or editing a volume. For example:

```
maprcli volume create -name
<volName> -path <mountPath> -schedule
<scheduleID>
```

```
maprcli volume modify -name
<volName> -schedule <scheduleID>
```

REST

You can associate a schedule with a volume using the `schedule` parameter when creating or editing a volume. Send a request of type POST. For example:

```
curl -X POST 'https://<hostname>:8443/
rest/volume/create?
name=<volName>&path=<volPath>&schedule
=<scheduleID>' --user
<username>:<password>
```

```
curl -X POST 'https://<hostname>:8443/
rest/volume/modify?
name=<volName>&schedule=<scheduleID>'
--user <username>:<password>
```

For the complete list of all required and optional parameters, see [volume create](#) on page 2929 and [volume modify](#) on page 3018.

Removing one or more Schedules

Describes how to remove schedules not associated with any volumes using either the Control System or the CLI.

About this task

You can remove a schedule only if it is not associated with any volumes.

Removing one or more Schedules Using the Control System

About this task

To remove one or more schedules, in the **Schedules** tab under **Data > Volumes**:

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

Procedure

1. Select the schedule(s) to remove from the list of schedules.
2. Click **Remove Schedule** to display the **Remove Schedule** confirmation dialog.
3. Verify the list of schedules to remove click **Remove Schedule** to remove the schedules.
When you remove a schedule, the schedule is removed from the system and cannot be restored.

Removing one or more Schedules Using the CLI or the REST API

About this task

The basic command to remove a schedule by ID is:

```
maprcli schedule remove -id <schedule ID>
```

For complete reference information, see [schedule remove](#) on page 2622.

Managing Tiers

About this task

You can create, modify, and remove tiers using the Control System and the CLI.

Enabling Tiering

Describes how to enable data tiering using both the Control System and the CLI.

For a primer on Data Tiering, see [Data Tiering](#) on page 575.

On all new installations, the data tiering functionality is enabled and available for all new volumes. If you are upgrading, you must enable data tiering; see [Step 4: Enable New Features](#) on page 492 for more information. If the data tiering functionality is enabled, you can then selectively enable tiering for a volume at the time of volume creation using the Control system and the CLI.

Data tiering is only available for new volumes; you cannot enable data tiering for existing volumes. Enable tiering for new volumes where read/write latency is not the dominant concern. You can decide later whether you want to do local (or warm) or remote (or cold) tiering. Data tiering cannot be disabled after it is enabled for a volume.

Enabling Tiering Using the Control System

1. Move the **Data Tier** slider to **Yes** (to enable tiering) in the **Create New Volume** page in the Control System.

Proceed to the next step only if you wish to select a tier type for the volume. You can create a tiering-enabled volume without selecting a tier type and select a tier type later by editing the volume.

NOTE: You cannot disable tiering for a volume after it is enabled.

2. (Optional) Select **Erasure Coding** (for warm tiering) or **Remote Archiving** (for cold tiering) from the **Tiering Type** drop-down menu.

You:

- Can enable a volume for either warm or cold tiering, but not for both.
- Cannot modify the tier type after the volume is created.

3. Specify all other required and optional properties for creating the volume and click **Create Volume**.
For information on required and optional properties, see [Creating a Volume](#) on page 1437.

Enabling Tiering Using the CLI

- Run the following command to enable tiering:

```
maprccli volume create -name <vol-name> -path <mount-path> -tieringenable true
```

For more information, see [volume create](#) on page 2929.

Introduction to Parallel Offload

The [MAST Gateway](#) uses parallel threads to rapidly offload tiering-enabled volumes to either cold or warm tiers.

Prior to HPE Data Fabric version 6.2, for any given volume, by default, only one MAST Gateway is used to offload the data. All tiering tasks such as offloads, recall, and compaction are scheduled only on that one assigned gateway. This causes multiple tasks to contend for limited threads on that assigned node, resulting in slowdowns. EC encoding performance is limited because of a single gateway. S3 offload throughput is limited as well. MAST Gateway utilization is skewed as some nodes may be idle, while others may be over utilized. When the assigned gateway goes offline, the volume is assigned a new gateway and the tasks are restarted.

To mitigate these issues with a single gateway, when a new cluster is setup with version 6.2 software, multiple MAST Gateways are used in parallel to offload the data of a single volume.

Parallel Offload uses one primary MAST Gateway and multiple secondary MAST Gateways per volume. The primary gateway coordinates tasks across secondary gateways and reports their final status to CLDB.

Only volume level offload tasks are sharded. File level tasks and all non-offload volume tasks are run on the primary gateway itself.

Advantages of Parallel Offload

Multiple MAST Gateways provide the following advantages:

- Increased per-volume throughput
- Leverage idle/unused cluster nodes
- Increased per-gateway efficiency

- Efficient usage of network bandwidth
- Leverage local reads to improve offload efficiency
- Only a subset of tasks need to be rescheduled if a gateway goes offline
- Resilient to failures
- Efficient volume and tasks level load balancing

Resiliency with Parallel Offload

Parallel Offload is resilient to the following scenarios:

Restart of the Primary Gateway

- Secondary gateways continue to run assigned tasks while the primary gateway is down or restarting.
- CLDB reassigns the volume to another primary gateway.
- CLDB restarts the tasks on the new primary gateway.
- The primary gateway polls/reschedules the ongoing secondary gateway tasks.

Restart of the Secondary Gateway

- The primary gateway detects the failure of secondary gateway tasks when it polls the secondary gateway.
- The primary gateway reschedules tasks that were terminated when the secondary gateway restarted.

Restart/Switchover of CLDB

- Reassign volume to the same primary gateway.
- Reschedule pending volume task on the same primary gateway.

Load Balancing with Parallel Offload

Load Balancing involves:

Volume Level

- CLDB assigns each volume to a gateway with the least number of volumes.
- Gateway Balancer reassigns volumes across gateways.

Task Level

CLDB balances tasks across MFS nodes.

Enabling Parallel Offload on an Upgraded Cluster

When the cluster is upgraded to version 6.2 from a previous release, only one MAST Gateway is used to offload the data of a single volume. To use multiple MAST Gateways, to offload a volume's data in parallel, you have to enable parallel offloads feature:

```
maprcli cluster feature enable -name mfs.feature.container.sharding.support
```

To check whether parallel offloads are enabled, run:

```
maprcli config load -json | grep -i shard
```

A value of 0 indicates that parallel offloads are enabled. For example:

```
"mastgateway.disable.sharding": "0"
```

Creating a Storage Tier

Describes how to create a storage tier using the Control System and the CLI.

About this task

For a primer on Data Tiering, see [Data Tiering](#) on page 575.

You can create a tier using the Control System and the CLI.

When you create a tier, file system creates a volume, whose mount point is `/var/mapr/tier/mapr.internal.tier.<tiername>`, for the tier. For warm tier volumes automatically created using the `ecenable` parameter or the Control System, by default, a corresponding tier volume named `mapr.internal.tier.autoec.<volName>.<creationTime>` is created in the `/var/mapr/autoectier` path. The tier volume is visible and stores all the metadata tables and information on all the jobs running on the tier. Do not modify, move, or remove this volume.

NOTE: If the number of cluster nodes is more than five, by default, HPE Data Fabric (through the `enforceminreplicationforio` parameter) requires minimum number of copies of the tier volume for writes to succeed. If the number of cluster nodes is less than five, HPE Data Fabric does not enforce minimum number of copies for writes to succeed.

Creating a Warm Tier Using the Control System

About this task

When you create a volume enabled for erasure coding, the control system automatically creates a warm tier and associates the volume with that tier. See [Creating a Volume](#) on page 1437 for more information. You cannot create a warm tier separately using the Control System.

Creating a Cold Tier Using the Control System

About this task

To create a cold tier:

Procedure

1. Log in to the Control System, click **Data > Volumes**, and then do one of the following:
 - Go to the **Remote Targets** tab if you wish to create a remote target that is not (yet) associated with a volume.
 - Click **Create Volume** if you wish to create a remote target for a volume when you are creating the volume.

NOTE: You must enable data tiering and select **Remote Archiving (Cold)** from the **Tiering Type** drop-down list to create the remote target.

- Click **Edit Volume** in the [volume information page](#) if you want to create a remote target for the volume when you are editing the volume settings.

NOTE: You can create a remote target only if a remote target is already not associated with the volume.

2. Click one of the following to display the **Create Remote Target** window.

- **Create Target** if you are in the **Remote Targets** tab.
- **Create** link associated with the **Remote Target** field if you are in the **Create New Volume** page.
- **Create** link associated with the **Remote Target** field if you are in the **Edit Volume** page.

3. Specify a name for the tier in the **Remote Target Name** field.

4. Select a topology for the metadata volume associated with the tier from the list of topologies in the **Lookup Topology** drop-down menu.

The volume stores all the metadata tables and information on all the jobs running on the tier. If many volumes share the same tier (and thus the same lookup topology), the lookups might have an adverse affect by inadvertently adding background load to nodes in that topology. This property allows you to setup the lookups on other nodes.

5. Specify the following properties.

Vendor	<p>The vendor from the Vendor drop-down list.</p> <p> NOTE: For cold tiering, HPE Data Fabric supports the following vendors:</p> <ul style="list-style-type: none"> • AWS (Amazon AWS) • GCS (Google Cloud Platform) • HDS (Hitachi HCP) • IBM (IBM Cleversafe) • Azure Blob (Microsoft Azure) • Others (such as Minio) <p>See Specifying the Vendor/Object Store for a Cold Tier on page 1554 for more information on the supported vendors.</p>
URL	<p>The URL to use to connect to the tier in the following format:</p> <pre><protocol>://<IP hostname>.<domain></pre> <p>If the protocol is <code>https</code>, the MAST Gateway uses HTTPS to upload data to the cold-tier. If the cold-tier storage does not support HTTPS, all tier related operations will fail. If the cold tier does not support HTTPS, set the protocol to <code>http</code>.</p> <p>See Specifying the Vendor/Object Store for a Cold Tier on page 1554 for more information on the tier endpoint URLs and supported authentication protocols.</p>
Bucket Name	<p>The name of the bucket on the tier. This cannot be modified once associated with a tier. If the bucket does not already exist on the tier, HPE Data Fabric will attempt to create the bucket.</p> <p> NOTE: For Azure, the bucket/container is created in the region that is specified in the parent storage account.</p>

Region	The S3 region to create the bucket on. This cannot be modified once configured (explicitly or using the default) and associated with a tier. See region on page 1552 for more information.
---------------	--

6. Enter the credentials for accessing the tier in the **Access Key** and **Secret Key** fields.

TIP: For Azure Blobs, the storage account name is the access key.

7. Click **Create Target** to create the cold tier that you can associate with a volume.

Creating a Tier Using the CLI and the REST API

About this task

CLI

Run the following command to create a tier:

- Cold tier:

```
$maprcli tier create -name
<tier_name> -type cold -url
<tier_url> -credential
<credentials_file_path>
```

For using the `-credential` option, you must have the credential file already set up as described in [Setting up a Credentials File for Connecting to a Cold Tier Using the CLI or REST API](#) on page 1551. On the other hand, if you do not have the file already set up, use the `-credential_str` option as follows:

```
$maprcli tier create -name
<tier_name> -type cold -url
<tier_url> -credential_str
'<credential_string>'
```

- Warm tier with default values:

```
$maprcli tier create -name
<tier_name> -type ectier
```

NOTE: You can associate the same tier with multiple volumes with different erasure coding scheme.

REST

Send a request of type POST. For example:

- Cold Tier:

```
# curl -X POST 'https://
server.sj.us:8443/rest/tier/create?
name=egColdTier&type=cold&url=s3.am
azonaws.com&credential=credentials.
txt' --user <username>:<password>
{"timestamp":1525724933919,"timeofd
ay":"2018-05-07 01:28:53.919
GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully
created tier: 'egColdTier'"]}
```

- Warm tier:

```
# curl -X POST 'https://
server.sj.us:8443/rest/tier/create?
name=egWarmTier&type=ectier' --user
<username>:<password>
{"timestamp":1525725105206,"timeofd
ay":"2018-05-07 01:31:45.206
GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully
created tier: 'egWarmTier'"]}
```

NOTE: You can associate the same tier with multiple volumes with different erasure coding scheme.

For more information, see [tier create](#) on page 2867.

Setting up a Credentials File for Connecting to a Cold Tier Using the CLI or REST API

Describes how to create a credential file, with examples for AWS and Microsoft Azure.

Set up a credentials file on the host you plan to use for creating the cold tier if you are planning on using the `credential` option (and not pass the credentials on the command-line using the `credential_str` option).

For example, your `credentials.txt` file for AWS should look similar to the following sample file:

```
{
  "bucketName" : "defaultbucket3",
  "region": "us-east-1",
  "credentials" : {
    "accessKey" : "AB956CDE8F2G07H9I4J2",
    "secretKey" : "5K1LmN92e65oPQRsTUV0fSbURxyEtYl2MmAocGi"
  }
}
```

The sample for Microsoft Azure is as follows:

```
maprcli tier create -name tier_azure_1 -type cold -url https://
myobjectpools1.blob.core.windows.net -credential ~/creds_azure.txt
$ cat creds_azure.txt
{
  "bucketName" : "bucket4",
  "credentials" : {
    "accessKey" : "myobjectpools1",
    "secretKey" :
```

```
"N6GKkDPttqNc6rfTzhb2JNKwvdr9EraN89Mg8WaodrvPBeINBTZwhQu+Q3vX4ENew+RQN42f+P8
nXN0YasZWNA=="
}
```

The credentials file (.txt file) contains the following properties in JSON format:

bucketName

The name of the bucket on the tier. If the bucket does not already exist on the tier, the command to create the tier attempts to create the bucket using the credentials in the credentials file. You can modify the name of the bucket only by using the -force option with the [tier modify](#) on page 2875 command

region

The S3 region to create the bucket on. Use the information in the following table to specify region information.

Vendor	Default Value	Notes
AWS	us-east-1	<p>Specify region information as defined here.</p> <p>On AWS, each region can have a different URL. The URL must be provided with the <code>mapcli tier create</code> command.</p> <p> NOTE: Because bucket names are unique across regions, make sure you specify the correct region for a given bucket in the credentials file. For example, suppose a bucket called <code>myBucket3</code> in <code>us-east-1</code>; you cannot offload data to <code>myBucket3</code> by specifying <code>us-west-1</code> as the region in the credentials file.</p>
GCS	us-east-1	Specify region information as described here .
HDP	N/A	Not required. If specified, Data Fabric ignores the value.

Vendor	Default Value	Notes
IBM	us-east-region	Not required. If specified, Data Fabric ignores the value.
Azure-Blobs	N/A	Not required. The region of the storage account is determined from the URL and data is offloaded into that region.
Minio	us-east-1	If you specify region, export the MINIO_REGION environment variable on the minio server as described in the Configuration Guide .
Scality	us-east-region	Not required. If specified, Data Fabric ignores the value.

You can modify the region only by using the `-force` option with the `tier modify` on page 2875 command.

accessKey and secretKey

The credentials for accessing the tier.

TIP: For Azure Blobs, the storage account name is the access key.

NOTE: Once the tier is created, Data Fabric does not require this file because CLDB stores the bucket, region, and credentials information.

Specifying the Vendor/Object Store for a Cold Tier

Specify the vendor or object store where you plan to offload the (cold) data. The following table lists the supported vendors, URL of the tier endpoint, and authentication protocol supported by Data Fabric:

Supported Vendor/Object Store	Tier URL/Endpoint	Supported Authentication Protocol
AWS (Amazon AWS)	<p>The URL varies based on the region. For:</p> <ul style="list-style-type: none"> us-east-1: https://s3.amazonaws.com us-east-2: https://s3.us-east-2.amazonaws.com us-west-1: https://s3-us-west-1.amazonaws.com us-west-2: https://s3-us-west-2.amazonaws.com ap-south-1: https://s3.ap-south-1.amazonaws.com ap-southeast-1: https://s3-ap-southeast-1.amazonaws.com ap-southeast-2: https://s3-ap-southeast-2.amazonaws.com ap-northeast-1: https://s3-ap-northeast-1.amazonaws.com ap-northeast-2: https://s3.ap-northeast-2.amazonaws.com ap-northeast-3: https://s3.ap-northeast-3.amazonaws.com ca-central-1: https://s3.ca-central-1.amazonaws.com cn-north-1: https://s3.cn-north-1.amazonaws.com cn-northwest-1: https://s3.cn-northwest-1.amazonaws.com eu-central-1: https://s3.eu-central-1.amazonaws.com eu-west-1: https://s3-eu-west-1.amazonaws.com eu-west-2: https://s3.eu-west-2.amazonaws.com eu-west-3: https://s3-eu-west-3.amazonaws.com 	<ul style="list-style-type: none"> HTTP HTTPS

Supported Vendor/Object Store	Tier URL/Endpoint	Supported Authentication Protocol
GCS (Google Cloud Platform)	https://storage.googleapis.com	<ul style="list-style-type: none"> • HTTP • HTTPS
HDS (Hitachi HCP)	http://<hcptenant>.<hcphostname> https://<hcptenant>.<hcphostname>	<ul style="list-style-type: none"> • HTTP • HTTPS
IBM (IBM Cleversafe)	http://lb1.aib.cleversafelabs.com	HTTP
Azure Blob (Microsoft Azure)	https://<azureaccount>.blob.core.windows.net	<ul style="list-style-type: none"> • HTTP • HTTPS
Minio	http://10.10.88.198:9000	HTTP
Scality	https://<scality-instance-hostname>:8000	HTTP

Viewing the List of Tiers

Describes how to view the list of tiers using the Control System, the CLI, and the REST API.

About this task

For a primer on Data Tiering, see [Data Tiering](#).

In the Control System, you can only see the list of cold tiers (referred to as remote targets). Use the CLI or REST API to retrieve the list of both cold and warm tiers.

Viewing the List of Remote Targets Using the Control System

Procedure

- Log in to the Control System and click **Data > Volumes > Remote Targets**.

The page displays the following for each remote target:

Column Name	Column Description
Remote Target Name	The name of the remote target.
External Storage Vendor	The name of the third-party storage vendor.
Bucket	The name of the bucket.
Region	The region where the bucket resides.
URL	The URL of the remote target.

You can:

- [Create a remote target](#)
- [Remove a remote target](#)

Viewing the List of Tiers Using the CLI and REST API

About this task

CLI

Run the following command to retrieve the list of (warm and cold) tiers:

```
/opt/mapr/bin/maprcli tier list
```

REST

Send a request of type GET. For example:

```
# curl -X GET 'https://
10.10.82.24:8443/rest/tier/
list' --user <username>:<password>
{"timestamp":1525725765483,"timeofday"
:"2018-05-07 01:42:45.483 GMT-0700
PM","status":"OK","total":0,"data":
[{"tierid":"79082078","tiername":"egwa
rmTier","tiertype":"ectier","volume":"
mapr.internal.tier.egWarmTier","topolo
gy":"/data"},
{"tierid":"120198852","tiername":"egCo
ldTier","tiertype":"cold","url":"s3.am
azonaws.com","bucketname":"ksekhar-tes
t","region":"us-east-1","volume":"mapr
.internal.tier.egColdTier","topology":
"/data","objectstoretype":"S3_AWS"},
{"tierid":"158778422","tiername":"auto
ec.vol_tiered.1525463214","tiertype":"
ectier","volume":"mapr.internal.tier.a
utoec.vol_tiered.1525463214","topology
":"/data"}]}
```

For more information, see [tier list](#) on page 2873.

Editing a Tier

Describes how to modify a cold tier using the Control System, the CLI and the REST API.

About this task

For a primer on Data Tiering, see [Data Tiering](#) on page 575.

You cannot modify a warm tier. You can modify a cold tier (referred to as Remote Target in the Control System) using the Control System, the CLI, and REST API.

Modifying a Remote Target Using the Control System

Procedure

1. Log in to the Control System and go to the **Remote Target** tab under **Data > Volumes**.
2. Click the name of the remote target (cold tier) to display the **Edit Remote Target** window.
3. Make necessary changes to the **CREDENTIALS**.
4. Click **Save Changes** to save the changes.

Modifying a Cold Tier Using the CLI and REST API

About this task

CLI

Run the following command to modify a cold tier:

```
$maprcli tier
modify -name <tier_name> -credential
<credentials_file_path>
```

REST

Send a request of type POST. For example:

```
curl -X POST 'https://abc.sj.us:8443/
rest/tier/modify?
name=<tier_name>&credential_str=<JSON>
' --user <username>:<password>
```

For more information, see [tier modify](#) on page 2875.

Specifying a Tier

Describes how to associate a tier with a tiering-enabled volume using the Control System and the CLI.

About this task

NOTE:

For a primer on Data Tiering, see [Data Tiering](#) on page 575.

Using the Control System, you can only associate an existing tier (referred to as **Remote Target** in the Control System) with a volume enabled for Remote Archiving (or cold-tier). You cannot associate an existing tier with a volume enabled for Erasure Coding (or warm-tier) because the Control System allows a new tier to be automatically created when you enable a volume for erasure coding. If you want to associate an existing tier with a volume enabled for erasure coding, use the CLI or REST API to create the volume.

Specifying a Remote Target Using the Control System

About this task

You can associate a remote target with a cold-tier enabled volume when you are:

- Creating the volume by clicking **Create Volume** button in the **Data > Volumes** page.
- Editing the volume by clicking **Edit Volume** button in the [volume information page](#).

To associate a remote target with the volume, in the **Create Volume** or **Edit Volume** page:

Procedure

1. Click the **Browse** link associated with the **Remote Target** field to display the **Browse Remote Target** window.
2. Review the name, vendor, bucket, region, and URL for each remote target and choose a remote target from the list.
3. Click **Select** to associate the remote target with the volume.
4. Complete the steps for [creating](#) or [editing](#) the volume.

Specifying a Tier Using the CLI and REST API

About this task

You can associate an existing tier with a volume when you are creating the tiering-enabled volume. You can associate an existing tier with a tiering-enabled volume when you are editing the volume only if the volume does not already have a tier associated with it. To associate an existing tier, you must specify the `tiername` parameter with the command.

CLI

Run a command similar to the following to associate a tier when:

- Creating a volume:

```
maprcli volume create -name
<volName> -path
<mountPath> -tieringenable
true -tiername <tierName> -json
```

For the list of all other required and optional parameters, see [volume create](#) on page 2929.

- Editing the volume:

```
maprcli volume modify -name
<volName> -tiername
<tierName> -json
```

For the list of all other required and optional parameters, see [volume modify](#) on page 3018.

REST

Send a request of type POST. For example, to associate a tier when:

- Creating a volume:

```
curl -X POST 'https://<host>:8443/
rest/volume/create?
name=<volName>&path=<mountPath>&tie
ringenable=true&tiername=<tierName>
&tieringrule=<ruleName>' --user
<username>:<password>
```

For the list of all other required and optional parameters, see [volume create](#) on page 2929.

- Editing the volume:

```
curl -X POST 'https://<host>:8443/
rest/volume/modify?
name=<volName>&tieringrule=<ruleNam
e>' --user <username>:<password>
```

For the list of all other required and optional parameters, see [volume modify](#) on page 3018.

Moving a Tier

Describes how to move a tier to a different database topology using both the Control System and the CLI. The operation is applicable to cold tiers only.

About this task

You can move a tier from the existing database topology to a different database topology in the same cluster by using the Control System and the CLI. A tier can be moved when the database topology for the tier gets bloated, and is required to be moved to a quieter part of the cluster.

Procedure

1. Log in to the Control System and navigate to **Data > Volumes**
 2. Click the **Remote Targets** tab.
-  **NOTE:** Cold tiers are referred to as remote targets.
3. Click **Change Topology**
 4. Select a new topology from the list of existing topologies seen under **The new value** drop-down.
 5. Click **Save Changes**.

Moving a Tier Using the CLI and the REST API

About this task

Explains moving a tier to a different database topology by using the CLI and REST API.

CLI

Run the following command to move a tier from one database topology to another:

```
$ maprcli tier move
[-cluster <cluster_name> ] -name
<tier_name> -dbtopology <path>
```

REST

Send a request of type POST by using the following syntax:

```
# curl -k -X POST 'https://
<host>:<port>/rest/tier/move?
name=<tier_name>&dbtopology=<rack_path
_of_destination_db_volume_topology>'
```

For more information, see [tier move](#) on page 2878.

Removing a Tier

Describes how to remove a tier that is not associated with a tier, using the Control System, the CLI and the REST API.

About this task

For a primer on Data Tiering, see [Data Tiering](#) on page 575.

You can remove a tier that is not associated with a volume, using the Control System, the CLI, and REST API. In the Control System, a cold tier is referred to as remote target and you can only remove remote targets (or cold tiers) using the Control System. Use the CLI or REST API to remove cold and warm tiers.

Removing a Remote Target Using the Control System

Procedure

1. Log in to the Control System and click **Data > Volumes > Remote Targets** to display the list of remote targets.
2. Select the checkbox associated with the tier to delete.
Selecting the checkbox associated with a tier makes the **Remove Target** button available.
3. Click **Remote Target** to display the **Remove Remote Target** confirmation dialog.
4. Verify the list of remote targets to remove and click **Remove**.

Removing a Tier Using the CLI and REST API

About this task

CLI

Run the following command to remove a tier:

```
/opt/mapr/bin/maprcli tier
remove -name <tier-name>
```

You cannot remove a tier associated with a volume. If you run the command to remove a tier that is associated with a volume, the command returns an error (shown in **bold**) similar to the following:

```
{
  "timestamp":1516771078126,
  "timeofday":"2018-01-23
09:17:58.126 GMT-0800",
  "status":"ERROR",
  "errors":[{"
    "id":10003,
    "desc":"Cannot remove tier,
as some volumes are still using it."
  }]}
}
```

REST API

Send a request of type POST to remove a tier. For example:

```
curl -X
POST 'https://abc.sj.us:8443/rest/
tier/remove?name=ksTestTier' --user
<username>:<password>
```

You cannot remove a tier associated with a volume. If you send a request to remove a tier that is associated with a volume, an error (shown in **bold**) similar to the following is returned:

```
# curl -X POST 'https://
server.sj.us:8443/rest/tier/remove?
name=ksTestTier' --user
<username>:<password>
{"timestamp":1524675381333,"timeofday"
:"2018-04-25 09:56:21.333 GMT-0700
AM","status":"ERROR","errors":
```

```
[{"id":10003,"desc":"Can not remove tier, as some volumes are still using it."}]}
```

For more information, see [tier remove](#) on page 2879.

Managing Storage Policies

About this task

Data offload is driven by rules, which are configured per volume. Data offload rule can be based on size of file (s), owner (u, g, or p) of the file, and/or file modification timestamp (m). You can apply one rule per volume.

When a rule is associated with a volume, the rule is first applied on the files in the tiering-enabled volume. When applied on the files in the tiering-enabled volume, the offload is triggered for all files in the snapshot chain as well when the criteria in the rule is met. If the file does not exist in the tiering-enabled volume, rule is applied on the latest state of the file in the snapshot chain. If the file exists in the tiering-enabled volume but has no latest state or if the file was deleted in the tiering-enabled volume, offload does not happen.

Rules can be defined using a combination of the following:

u	Username or user ID, as configured in the OS registry (such as /etc/passwd file, LDAP, etc.), of a specific user. Usage: u:<username or user ID>
g	Group name or group ID, as configured in the OS registry (such as /etc/group file, LDAP, etc.), of a specific group. Usage: g:<groupname or group ID>

a	<p>(<i>atime</i>) Time (in seconds or days) since the files were last accessed. The number of seconds can be specified by appending <i>s</i> to value and the number of days can be specified by appending <i>d</i> to the value.</p> <p>Usage:</p> <ul style="list-style-type: none"> • "<i>a</i>:<value><i>s</i>" — specifies <i>atime</i> in seconds • "<i>a</i>:<value><i>d</i>" — specifies <i>atime</i> in days <p> NOTE: If the system time on CLDB and file server nodes are different, the <i>atime</i> rule for offloading data may not work as intended.</p> <p>This tier rule is matched and files are offloaded, when all of the following conditions are met:</p> <ol style="list-style-type: none"> 1. <i>atime</i> tracking is enabled at volume level 2. Time since <i>atime</i> that is configured on the volume is more than the time specified in the rule 3. Duration since the file was last accessed is more than the time specified in the rule <p>Assume that the <i>atime</i> feature is enabled on the volume and that the time in the rule is set to a:300s. Based on this rule, all files that are not accessed since 300s, are offloaded. However, this rule is valid only if time since <i>atime</i> tracking is enabled, is more than 300s. The volume level parameter <i>atimeTrackingStartTime</i> denotes the start time of <i>atime</i>.</p> <p>For more information, see Tuning Last Access Time on page 599.</p>
m	<p>(<i>mtime</i>) Time (in seconds or days) since the files were last modified. The number of seconds can be specified by appending <i>s</i> to value and the number of days can be specified by appending <i>d</i> to the value.</p> <p>Usage:</p> <ul style="list-style-type: none"> • "<i>m</i>:<value><i>s</i>" — specifies <i>mtime</i> in seconds • "<i>m</i>:<value><i>d</i>" — specifies <i>mtime</i> in days <p>All files that are not modified since the specified amount of time, are offloaded.</p> <p> NOTE: If the system time on CLDB and file server nodes are different, the <i>mtime</i> rule for offloading data may not work as intended.</p>

s	<p>The size of the file in bytes, kilobytes, megabytes, or gigabytes. The size of the file can be specified by appending one of the following to the value: b for bytes, k for kilobytes, m for megabytes, or g for gigabytes.</p> <p>Usage</p> <ul style="list-style-type: none"> "s:<value>b" — specifies file size in bytes "s:<value>k" — specifies file size in KB "s:<value>m" — specifies file size in MB "s:<value>g" — specifies file size in GB <p>All files whose size exceeds the specified size are offloaded.</p>
---	--

Or, use the following:

p	(Default) Specifies all files. Specifies that this operation is applicable to all the files without restriction. This cannot be combined with any other operator.
" "	Indicates none of the files. Specifies that this operation cannot be performed on any of the files.

Use the following to string multiple criteria for offload:

&	AND operation to combine multiple expressions as the criteria for the rule.
	OR operation to indicate either of the expressions as the criteria for the rule.
()	Delimiters for subexpressions.

For volumes configured for erasure coding, a default storage policy, `default.ectier.rule` (ID 1 and expression p), is applied if one is not specified.

You can create, associate, and remove rules using the Control System, the CLI, and REST API.

Creating a Storage Tier Policy

Explains how to create a tiering policy for storage using either the Control System, the CLI, or the REST API.

Creating a Storage Tier Policy Using the Control System

About this task

To create a storage tier policy (or rule) using the Control System:

Procedure

1. Log in to the Control System, click **Data > Volumes**, and then do one of the following:

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

- Go to the **Storage Policies** tab if you wish to create a storage policy that is not (yet) associated with a volume.

- Click **Create Volume** if you wish to create a storage policy for a volume when you are creating the volume.

NOTE: You must enable data tiering to create the storage policy.

- Click **Edit Volume** in the [volume information page](#) if you wish to create a storage policy for a volume when you are editing the volume settings.
- Click one of the following to display the **Create Storage Policy** dialog.
 - Create Policy** if you are in the **Storage Policies** tab.
 - Create** link associated with the **Storage Policy** field if you are in the **Create New Volume** page.
 - Create** link associated with the **Storage Policy** field if you are in the **Edit Volume** page.
 - Enter a name for the storage policy in the **Storage Policy Name** text field.
 - Choose **Build rule** or **Rule expression** radio button to define the criteria for offloading data. Use the **Build rule** option to build simple rules. Click **Add Condition** to add one of the following entities:
 - Group
 - User
 - File size
 - Time since the file was modified
 - Time since the file was accessed

Use a condition group, to add AND and OR conditions.

Click **Add condition group** to add AND and OR conditions. You can toggle the AND and OR conditions as needed.

Use the **Rule expression** option to create advanced rules that comprise a combination of the following expressions:

u	Username or user ID, as configured in the OS registry (such as /etc/passwd file, LDAP, etc.), of a specific user. Usage: u:<username or user ID>
g	Group name or group ID, as configured in the OS registry (such as /etc/group file, LDAP, etc.), of a specific group. Usage: g:<groupname or group ID>

a	<p>(<i>atime</i>) Time (in seconds or days) since the files were last accessed. The number of seconds can be specified by appending <i>s</i> to value and the number of days can be specified by appending <i>d</i> to the value.</p> <p>Usage:</p> <ul style="list-style-type: none"> • "<i>a</i>:<value><i>s</i>" — specifies <i>atime</i> in seconds • "<i>a</i>:<value><i>d</i>" — specifies <i>atime</i> in days <p> NOTE: If the system time on CLDB and file server nodes are different, the <i>atime</i> rule for offloading data may not work as intended.</p> <p>This tier rule is matched and files are offloaded, when all of the following conditions are met:</p> <ol style="list-style-type: none"> <i>atime</i> tracking is enabled at volume level Time since <i>atime</i> that is configured on the volume is more than the time specified in the rule Duration since the file was last accessed is more than the time specified in the rule <p>Assume that the <i>atime</i> feature is enabled on the volume and that the time in the rule is set to a:300s. Based on this rule, all files that are not accessed since 300s, are offloaded. However, this rule is valid only if time since <i>atime</i> tracking is enabled, is more than 300s. The volume level parameter <i>atimeTrackingStartTime</i> denotes the start time of <i>atime</i>.</p> <p>For more information, see Tuning Last Access Time on page 599.</p>
m	<p>(<i>mtime</i>) Time (in seconds or days) since the files were last modified. The number of seconds can be specified by appending <i>s</i> to value and the number of days can be specified by appending <i>d</i> to the value.</p> <p>Usage:</p> <ul style="list-style-type: none"> • "<i>m</i>:<value><i>s</i>" — specifies <i>mtime</i> in seconds • "<i>m</i>:<value><i>d</i>" — specifies <i>mtime</i> in days <p>All files that are not modified since the specified amount of time, are offloaded.</p> <p> NOTE: If the system time on CLDB and file server nodes are different, the <i>mtime</i> rule for offloading data may not work as intended.</p>

s	<p>The size of the file in bytes, kilobytes, megabytes, or gigabytes. The size of the file can be specified by appending one of the following to the value: b for bytes, k for kilobytes, m for megabytes, or g for gigabytes.</p> <p>Usage</p> <ul style="list-style-type: none"> "s:<value>b" — specifies file size in bytes "s:<value>k" — specifies file size in KB "s:<value>m" — specifies file size in MB "s:<value>g" — specifies file size in GB <p>All files whose size exceeds the specified size are offloaded.</p>
---	--

Or, use the following:

p	(Default) Specifies all files. Specifies that this operation is applicable to all the files without restriction. This cannot be combined with any other operator.
""	Indicates none of the files. Specifies that this operation cannot be performed on any of the files.

Use the following to string multiple criteria for offload:

&	AND operation to combine multiple expressions as the criteria for the rule.
	OR operation to indicate either of the expressions as the criteria for the rule.
()	Delimiters for subexpressions.

If a rule is not defined, the default rule, which is all files (p), is associated with the storage policy.

5. Click **Create Policy** to create the storage policy.

Creating a Rule Using the CLI and REST API

About this task

CLI

Run the following command to create a rule:

```
$ maprcli tier rule create -name
<rule_name> -expr <expressions>
```

REST

Send a request of type POST. For example:

```
# curl -X POST 'https://
abc.sj.us:8443/rest/tier/rule/create?
name=rule1&expr=m:365d' --user
<username>:<password>
{"timestamp":1519681475025,"timeofday"
:"2018-02-26 01:44:35.025 GMT-0800
PM","status":"OK","total":0,"data":
[],"messages":["Successfully created
rule: 'rule1'"]}
```

For more information, see [tier rule create](#) on page 2880.

Viewing the List of Storage Tier Policies

Explains how to view tiering policies for storage using either the Control System, the CLI, or the REST API.

Viewing the List of Storage Tier Policies Using the Control System

Procedure

- Log in to the Control System and click **Data > Volumes > Storage Policies**.

NOTE: The **Storage Policies** tab is under the **Volumes** menu in the Kubernetes version of the Control System.

The list of storage policies displays. For each storage policy, the page displays the following:

Column Name	Column Description
Policy Name	The name of the policy.
Detail	The policy details.

You can:

- [Create a Policy](#)
- [Edit a Policy](#)
- [Remove a Policy](#)

Viewing the List of Storage Tier Policies Using the CLI and REST API

About this task

CLI

Run the following command to retrieve the list of tiers:

```
# maprccli tier rule list
```

REST

Send a request of type GET. For example:

```
# curl -X GET 'https://server.sj.us:8443/rest/tier/rule/list' --user <username>:<password>
{"timestamp":1525728727729,"timeofday":"2018-05-07 02:32:07.729 GMT-0700 PM","status":"OK","total":6,"data":[{"ruleid":"1","rulename":"default.ectier.rule","expression":"m:1d"}, {"ruleid":"2","rulename":"rule2","expression":"s:5g"}, {"ruleid":"3","rulename":"rule1","expression":"m:365d"}, {"ruleid":"4","rulename":"rule3","expression":"u:m7user1"}, {"ruleid":"5","rulename":"rule4","expression":"p"}, {"ruleid":"6","rulename":"testRule","expression":"u:m7user1 | (u:mapr & (s:5g | m:365d))"}]}
```

For more information, see [tier rule list](#) on page 2887.

Modifying a Storage Tier Policy

Explains how to modify a storage tier policy using either the Control System, CLI, or the REST API.

About this task

If you modify a rule that is currently in use, the changes in the rule are only applied on future offloads; data offloaded using existing rule is not impacted by the change in the rule.

Modifying a Rule Using the Control System

Procedure

- 1. Log in to the Control System and go to **Storage Policies** tab in the **Data > Volumes** page.

NOTE: The **Storage Policies** tab is under the **Volumes** menu in the Kubernetes version of the Control System.

The list of storage policies displays.

- 2. Click the storage policy name to display the **Edit Storage Policy** window.

- 3. Make changes to the rule:

You can modify the basic rule to:

- Add (+) or remove (-) users and/or groups.
- Change the name of the users and/or groups.
- Change the number of days since the file was last modified for users and/or groups.

If you switch from a basic rule to an advanced rule, all expressions from the basic rule are carried over to the advanced rule. You can modify an advanced rule using a combination of the following expressions:

u	Username or user ID, as configured in the OS registry (such as /etc/passwd file, LDAP, etc.), of a specific user. Usage: u:<username or user ID>
g	Group name or group ID, as configured in the OS registry (such as /etc/group file, LDAP, etc.), of a specific group. Usage: g:<groupname or group ID>

a	<p>(<i>atime</i>) Time (in seconds or days) since the files were last accessed. The number of seconds can be specified by appending <i>s</i> to value and the number of days can be specified by appending <i>d</i> to the value.</p> <p>Usage:</p> <ul style="list-style-type: none"> • "<i>a</i>:<value><i>s</i>" — specifies <i>atime</i> in seconds • "<i>a</i>:<value><i>d</i>" — specifies <i>atime</i> in days <p> NOTE: If the system time on CLDB and file server nodes are different, the <i>atime</i> rule for offloading data may not work as intended.</p> <p>This tier rule is matched and files are offloaded, when all of the following conditions are met:</p> <ol style="list-style-type: none"> <i>atime</i> tracking is enabled at volume level Time since <i>atime</i> that is configured on the volume is more than the time specified in the rule Duration since the file was last accessed is more than the time specified in the rule <p>Assume that the <i>atime</i> feature is enabled on the volume and that the time in the rule is set to a:300s. Based on this rule, all files that are not accessed since 300s, are offloaded. However, this rule is valid only if time since <i>atime</i> tracking is enabled, is more than 300s. The volume level parameter <i>atimeTrackingStartTime</i> denotes the start time of <i>atime</i>.</p> <p>For more information, see Tuning Last Access Time on page 599.</p>
m	<p>(<i>mtime</i>) Time (in seconds or days) since the files were last modified. The number of seconds can be specified by appending <i>s</i> to value and the number of days can be specified by appending <i>d</i> to the value.</p> <p>Usage:</p> <ul style="list-style-type: none"> • "<i>m</i>:<value><i>s</i>" — specifies <i>mtime</i> in seconds • "<i>m</i>:<value><i>d</i>" — specifies <i>mtime</i> in days <p>All files that are not modified since the specified amount of time, are offloaded.</p> <p> NOTE: If the system time on CLDB and file server nodes are different, the <i>mtime</i> rule for offloading data may not work as intended.</p>

s	<p>The size of the file in bytes, kilobytes, megabytes, or gigabytes. The size of the file can be specified by appending one of the following to the value: b for bytes, k for kilobytes, m for megabytes, or g for gigabytes.</p> <p>Usage</p> <ul style="list-style-type: none"> "s:<value>b" — specifies file size in bytes "s:<value>k" — specifies file size in KB "s:<value>m" — specifies file size in MB "s:<value>g" — specifies file size in GB <p>All files whose size exceeds the specified size are offloaded.</p>
---	--

Or, use the following:

p	(Default) Specifies all files. Specifies that this operation is applicable to all the files without restriction. This cannot be combined with any other operator.
""	Indicates none of the files. Specifies that this operation cannot be performed on any of the files.

Use the following to string multiple criteria for offload:

&	AND operation to combine multiple expressions as the criteria for the rule.
	OR operation to indicate either of the expressions as the criteria for the rule.
()	Delimiters for subexpressions.

You cannot switch from an advanced rule that includes the following to a basic rule because the following are not supported in a basic rule:

- p — All the files
- s — The size of the file
- & — The AND operation used for specifying multiple users (u), groups (g), or criteria
- | — The OR operation used with s or m
- "" — None of the files.
- () — Subexpressions

NOTE: The basic rule must contain mtime (m). It can also include one or more users or groups separated by the OR operation (|).

4. Click **Save Changes** to save the storage policy changes.

Modifying a Rule Using the CLI and the REST API

About this task

CLI

Run the following command to modify a storage policy:

```
$ maprcli tier rule modify -name
<rule_name> -json
```

REST API

Send a request of type POST. For example:

```
# curl -X POST 'https://
server.sj.us:8443/rest/tier/rule/
modify?
name=sampleRule&expr=m:3d' --user
<username>:<password>
{"timestamp":1523587392465,"timeofday"
:"2018-04-12 07:43:12.465 GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully updated
rule: 'sampleRule'"]}
```

For more information, see [tier rule modify](#) on page 2888.

Specifying a Storage Tier Policy

Explains how to associate a storage tier policy with a tiering-enabled volume using either the Control System or the CLI.

Specifying a Storage Tier Policy Using the Control System

About this task

You can associate a storage policy with a tiering-enabled volume when you are:

- Creating a volume by clicking **Create Volume** in the **Data > Volumes** page.

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

- Editing the tiering-enabled volume by clicking **Edit Volume** button in the [volume information page](#).

To associate a storage policy with the volume, in the **Create Volume** or **Edit Volume** page:

Procedure

1. Click the **Browse** link associated with the **Storage Policy** field to display the **Browse Storage Policies** window.
2. Review the name and detail of each storage policy and choose a storage policy from the list.
3. Click **Select** to associate the storage policy with the volume.
4. Complete the steps for [creating](#) or [editing](#) the volume.

Specifying a Storage Tier Policy Using the CLI and REST API

About this task

You can associate a rule with a tiering-enabled volume by specifying the `tieringrule` parameter with the [volume create](#) on page 2929 or [volume modify](#) on page 3018 command.

CLI

Run a command similar to the following to associate a rule when:

- Creating a volume:

```
maprcli volume create -name
<volName> -path
<mountPath> -tieringenable
true -tiername
<tierName> -tieringrule
<ruleName> -json
```

For the list of all other required and optional parameters, see [volume create](#) on page 2929.

- Editing the volume:

```
maprcli volume modify -name
<volName> -tieringrule
<ruleName> -json
```

For the list of all other required and optional parameters, see [volume modify](#) on page 3018.

REST

Send a request of type POST. For example, to associate a rule when:

- Creating a volume:

```
curl -X POST 'https://<host>:8443/
rest/volume/create?
name=<volName>&path=<mountPath>&tie
ringenable=true&tiername=<tierName>
&tieringrule=<ruleName>' --user
<username>:<password>
```

For the list of all other required and optional parameters, see [volume create](#) on page 2929.

- Editing the volume:

```
curl -k -X POST 'https://
<host>:8443/rest/volume/modify?
name=<volName>&tieringrule=<ruleNam
e>' --user mapr:mapr
```

For the list of all other required and optional parameters, see [volume modify](#) on page 3018.

Removing a Storage Policy

Explains how to remove tiering policies for storage using either the Control System, the CLI, or the REST API.

About this task

WARNING: You cannot remove a storage policy that is associated with a volume.

Removing a Rule Using the Control System

Procedure

1. Log in to the Control System and go to **Storage Policies** tab under **Data > Volumes**.

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

The list of storage policies displays.

2. Select the checkbox associated with the storage policy to remove and click **Remove Policy**.
The **Remove Policy** confirmation window displays.
3. Review the list of policies to remove and click **Remove**.

Removing a Rule Using the CLI and the REST API

About this task

CLI

Run the following command to remove a storage policy that is not associated with a volume:

```
# maprcli tier rule remove -name
<rule_name>
```

If you try to remove a rule associated with a volume, the command returns an error (shown in bold) similar to the following:

```
# maprcli tier rule remove -name
rule1 -json
{
  "timestamp":1516771655669,
  "timeofday":"2018-01-23
09:27:35.669 GMT-0800",
  "status":"ERROR",
  "errors":[{"
    "id":10003,
    "desc":"Cannot remove rule, as
some volumes are still using it."
  }]
}
```

REST

Send a request of type POST. For example:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/rule/remove?
name=sampleRule' --user mapr:mapr
{"timestamp":1523571783113,"timeofday"
:"2018-04-12 03:23:03.113 GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully deleted
rule: 'sampleRule'"]}
```

If you try to remove a storage policy associated with a volume, the response contains an error (shown in bold) similar to the following:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/rule/remove?
name=sampleRule' --user mapr:mapr
{"timestamp":1523571741636,"timeofday"
:"2018-04-12 03:22:21.636 GMT-0700
PM","status":"ERROR","errors":
[{"id":10003,"desc":"Can not remove
rule, as some volumes are still using
it."}]}
```

For more information, see [tier rule remove](#) on page 2890.

Using Storage Labels

Describes the Storage Labels feature.

Synopsis of the Storage Labels Feature

Different applications have different requirements such as low latency, high throughput, and low variance in response times. Storage devices with various characteristics, for example SSD over SATA or SSD over NVME, are available as off-the-shelf storage. Therefore, it is now possible to cater exactly to the storage requirements of each application.

The Storage Label feature allows you to store particular kinds of data on particular classes of devices. For example, you could place data that needs to be fetched with lower latency on Solid State Drives (SSD), while placing data that can afford to be fetched with higher latency on Hard Disk Drives (HDD). Both classes of devices can be on the same node.

Use Cases for Storage Labels

Example use cases include:

- Latency-sensitive data can be placed on SSD, while data that is very rarely read can be placed on HDD.
- Active (warm) data can be placed on SSD while rarely used (cold) and archived data can be placed on HDD.
- Local volumes for Map Reduce tasks can be placed on SSD.
- Data can be securely segregated. For example, all finance data can be placed on volumes marked *finance*, engineering data on volumes marked *engineering*, and HR on volumes marked *HR*.

Components of the Storage Labels Feature

Storage Labels help you confine volumes to specific storage pools, to meet your desired objectives (such as low latency).

The Storage Labels feature has three main components: Labels, Storage Pools and Volumes.

What is a Label?

The Label acts as the bridge between a Storage Pool and a Volume.

The Label is a tag that associates a Volume with a Storage Pool. For example, a volume marked SSD will always be placed on a Storage Pool marked with the name SSD.

Labels have the following characteristics:

- Are a string of printable ASCII characters that should begin with a letter or a number in most cases, except when they represent device classes. For a device class, the label may contain properties that are enforced when the label is assigned to a Storage Pool or a Volume. For example, label **SSD** could have the following properties:

```
{
  num_disks_per_instance; #used in partitioning disks among multiple
  instances of a file server
                           on the same node.
  max_active_io_per_disk; # Number of concurrent IO operations to be used
  on the disk.
}
```

- Are case-insensitive.
- Have a internal numeric value attached to each of them.
- Have to be registered with the CLDB before use.

What is a Storage Pool?

In the HPE Data Fabric platform, a storage pool (SP) constitutes a logical storage device. A SP can be composed of SSDs, while another SP can be composed of HDDs. A heterogeneous SP that is made up of different classes of devices is not permitted.

However, multiple classes of SPs can reside on the same node.

You can assign a single label to each SP to identify it. A SP that has not been labeled, automatically assumes the **default** label (with an internal numeric value of 0).

What is a Volume?

In the HPE Data Fabric platform, a volume is the logical unit for a class of data. Therefore, storing various types of data on various classes of devices is essentially placing particular volumes on the appropriate classes of devices.

Each volume can have only one label. Volumes that do not have a label, assume the **default** label with a numeric value of 0.

The CLDB servers are responsible for keeping track of these labels and moving volumes across storage pools based on these labels.

A volume is placed only on the SP matching its label. A volume labelled **SSD** is placed only on a SP with the label **SSD**. Similarly, a volume with the **default** label, will only be placed on a SP with the **default** label.

To override this matching placement, use the special label **anywhere** for a volume. A volume with the **anywhere** label is placed on any SP irrespective of its label. Use this label frugally as you might inadvertently end up storing a volume on your expensive disks where it is not needed to be stored.

The Disk Balancer takes care of moving volumes to appropriate SPs as needed. For example, assume that a volume with a label marked **anywhere** is stored on a SP with a label **SSD**. Now a request comes in to place volumes that are explicitly labelled as **SSD** but there are no more SPs labelled as **SSD**. The Disk Balancer will then move the volume marked **anywhere** off the SP labelled as **SSD** on to any other SP, and accommodate the volumes explicitly labelled as **SSD**.

You might assign a label to a namespace container of a volume. If a label is not assigned, the namespace container inherits the label of its data container. The namespace label is NOT changed when moving a volume from one label to another. The namespace inherits the data container label at the time of volume creation if you do not specify a label to a namespace container explicitly.

However, if you assign a label to a namespace container but not to a data container, the data container is assigned the **default** label.

Once the data container and the namespace container are labelled, their labels are independent of each other.

At the time of Volume creation, the system chooses the SPs with matching labels. If the volume or its namespace container is associated with a label, creation fails if there are insufficient nodes with SPs having the same label.

If only one matching SP is present for a 2/3-way replicated volume, only a single replica is created for that volume.

When creating containers, the system checks for nodes/storage pools with matching labels in the topology requested. Container creation fails if there are no nodes/storage pools with matching labels in the topology requested, even if there are such nodes/storage pools in other topologies.

When the label of a volume is changed, replicas cannot be migrated within the file server, from one SP with the old label to another SP with the desired label. If there are no other SPs, all old copies will not be fully migrated to the new desired label.

ATTENTION: CLDB volumes are an exception. CLDB volumes can be created on any storage pool. Labels do not apply to CLDB volumes.

Enable the Storage Labels Feature on an Upgraded Cluster

The Storage Labels feature is already enabled on a new HPE Data Fabric version 6.2 cluster.

On a cluster upgraded to version 6.2, enable the Storage Labels feature with the command:

```
maprcli cluster feature enable -name cldb.lbs.support
```

This feature takes effect immediately without the need to fail over CLDB. This feature cannot be disabled once it is enabled.

Usage Sequence

You must perform label creation and assignment in the following sequence:

1. [Register a label](#) - Ensures that random labels are not assigned to SPs and Volumes. A label once registered cannot be deleted or prevented from being used.
2. [Assign a label to a Storage Pool](#) - Select any disk in the SP to assign a label. You can [create a storage pool](#), and [simultaneously set its label as well](#).
3. [Assign a label to a volume](#). You can assign a label at volume creation using the [volume create](#) on page 2929 command.

Override Topology and Storage Pool Adherences

You can override topology and SP adherences for critically under-replicated containers. The Storage Labels feature contains the following two settings.

- `honor.topology.for.critical.replication` - default value is `1` (true). When set to `0` (false), critically under-replicated containers are replicated outside their topology, if space is not available within their topology.

```
/opt/mapr/bin/maprcli config save -values
'{"honor.topology.for.critical.replication":"0"}'
```

- `honor.label.for.critical.replication` - default value is `1` (true). When set to `0` (false), critically under-replicated containers are replicated on other SPs, even if their labels do not match the labels of the SPs.

```
/opt/mapr/bin/maprccli config save -values
'{"honor.label.for.critical.replication":"0"}'
```

Storage Label Commands

Use the [label add](#) on page 2551 command to register a label.

Use the [disk add](#) on page 2418 or the [disk setlabel](#) on page 2420 command to label an SP.

Use the [volume create](#) on page 2929 or the [volume move](#) on page 3039 command to label a volume.

Use the [label list](#) on page 2555 command to list all registered labels.

Use the [node list](#) on page 2570 command to list all labels associated with a node.

Use the [dashboard info](#) on page 2401 command to view the list of registered labels and the number of associated volumes and storage pools.

Use the [mrconfig sp list](#) command to view all storage pool information, including the labels associated with the storage pools.

Use the [disk list](#) command to view the labels associated with disks.

Returns information about volumes and the associated containers. For JSON formatted output, use the `-json` option from the command line.

[configure.sh](#) on page 3186

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Data Fabric client nodes, and configuring services for a node.

Administering Files and Directories

The following sections provide configuration information that you can use to set chunk size and compression in file system, as well as information on hard links, extended attributes, and core files:

Using Global File System Checking

Describes how to use the `gfsck` command to check and repair file system errors.

About this task

You can use the [gfsck](#) on page 3241 (global file system check) command to perform a consistency check and repair operation on a volume or volume snapshot, including the following entities:

- All cross-container links (for example, from file to [filelet](#), or from table to tablets)
- The tabletmap key range
- The attributes of [filelet](#) (uid/gid/mode)

This command identifies the unreachable files, directories, and tables in the volume, and moves them to `/lost+found` to be repaired. It also identifies and fixes any unreachable DB inodes or dangling pointers to lost inodes.

The following table describes how the [gfsck](#) on page 3241 utility handles the objects based on the object size.

Table

Object Size	How gfsck handles the Object
Tiny objects	<code>gfsck</code> cannot re-construct tiny objects. <code>gfsck</code> cannot repair tiny objects.
Small objects	<code>gfsck</code> can re-construct small objects. The re-constructed object file name has the same name as that of the original object file name.
Large objects	<code>gfsck</code> can re-construct large objects. The re-constructed object file name differs from the original object file name. The filename of the re-constructed large object is <code>large_objs_reconstruct_<fid></code> , where <code>fid</code> denotes the file ID of the original object.
Jumbo objects	<code>gfsck</code> can re-construct jumbo objects. The re-constructed object file name differs from the original object file name. The filename of the re-constructed jumbo object is <code>jumbo_objs_reconstruct_<fid></code> , where <code>fid</code> denotes file ID of the original object.

Procedure

1. Take the affected storage pools offline by running the [mrconfig sp offline](#) on page 3333 command. For example:

```
/opt/mapr/server/mrconfig sp offline /dev/sdc
```

2. Execute the [fsck](#) on page 3239 command on the storage pools or disks.

3. Bring the storage pools back online by running the `mrconfig sp online` on page 3334 command.

For example:

```
mrconfig sp online /dev/sdc
```

4. Run the `gfsck` command on the affected volumes, or snapshots, with the appropriate options. If there are alarms, such as `DataUnavailableAlarm` or `DataUnderReplicatedAlarm`, do not run the `gfsck` command with the `-r` (`--repair`) option. Running the `gfsck` command with the `-r` (`--repair`) option, might result in data loss. If necessary, first run `gfsck` without the `-r` (`--repair`) option, and attempt to repair only after analyzing the command output.

Troubleshooting

While running the `gfsck` command with the `--use-aux-memory` option, you might encounter the following error in the `gfsck.log` file, when the `auxDBTables` directory is missing or has been removed accidentally:

```
ERROR com.mapr.fs.globalfsck.GlobalFsk createLargeObjectTable [main]:
AuxDb volume mapr.gfsck does not exist.
```

Cause: The `/var/mapr/auxDBTables` directory is missing.

Resolution: Restart the warden service. Restarting the warden service creates the `auxDBTables` directory in the `/var/mapr` directory.

Related reference

[gfsck](#) on page 3241

Describes how you can use the `gfsck` command, under the supervision of HPE Data Fabric Support or Engineering, to perform consistency checks and appropriate repairs on a volume, or a volume snapshot.

Setting file system Permissions

The Data Fabric file system permissions are similar to the POSIX permissions model. Each file and directory is associated with a user (the *owner*) and a group. You can set read, write, and execute permissions separately for:

- the owner of the file or directory.
- members of the group associated with the file or directory.
- all other users.

The permissions for a file or directory are called its *mode*. The mode of a file or directory can be expressed in two ways:

- Text - a string that indicates the presence of the read (r), write (w), and execute (x) permission or their absence (-) for the owner, group, and other users respectively. Example: `rwxr-xr-x`
- Octal - three octal digits (for the owner, group, and other users), that use individual bits to represent the three permissions. Example: `755`

Both `rwxr-xr-x` and `755` represent the same mode; the owner has all permissions, and the group and other users have read and execute permissions only.

When you [access the file system layer over NFS](#), the file-level permissions are controlled through the Linux interface by using the `chmod` (change mode) command or the `chown` (change owner) command, as well as the `hadoop fs -chmod` and `hadoop fs -chown` equivalents. For example:

```
chown jsmith /mapr/my.cluster.com/jsmith/fileA
hadoop -fs chown jsmith /mapr/my.cluster.com/jsmith/fileA
chmod 744 /mapr/my.cluster.com/jsmith/fileA
hadoop -fs chmod 744 /mapr/my.cluster.com/jsmith/fileA
```

These commands grant a user whose username is `jsmith` the read, write, and execute privileges on `fileA`.

Once you set file permissions, authorization checks are performed when a file is opened, *and* on every file access.

NOTE: To further protect your data, the Data Fabric file system data cache is never included in a file server core dump.

Text Modes

String modes are constructed from the characters in the following table:

Text	Description
u	The file's owner.
g	The group associated with the file or directory.
o	Other users (users that are not the owner, and not in the group).
a	All (owner, group and others).
=	Assigns the permissions Example: "a=rw" sets read and write permissions and disables execution for all.
-	Removes a specific permission. Example: "a-x" revokes execution permission from all users without changing read and write permissions.
+	Adds a specific permission. Example: "a+x" grants execution permission to all users without changing read and write permissions.
r	Read permission
w	Write permission
x	Execute permission

Octal Modes

To construct each octal digit, add the value of each permission that you want to grant:

- Read: 4
- Write: 2
- Execute: 1

For example, 7 which provides read, write, and execute permissions because $4+2+1=7$.

Syntax

You can change the modes of directories and files in the Data Fabric storage using either the `hadoop fs -chmod` command with the `-chmod` option, or using the `chmod` command via NFS. The syntax for both commands is similar:

- `hadoop fs -chmod [-R] <MODE>[,<MODE>]... | <OCTALMODE> <URI> [<URI> ...]`
- `chmod [-R] <MODE>[,<MODE>]... | <OCTALMODE> <URI> [<URI> ...]`

Parameters and Options

The following table provides the command parameters and options with their descriptions:

Parameter/Option	Description
-R	If specified, this option applies the new mode recursively throughout the directory structure.
MODE	A string that specifies a mode.
OCTALMODE	A three-digit octal number that specifies the new mode for the file or directory.
URI	A relative or absolute path to the file or directory for which to change the mode.

Examples

The following examples are all equivalent:

- `chmod 755 script.sh`
- `chmod u=rwx,g=rx,o=rx script.sh`
- `chmod u=rwx,go=rx script.sh`

Managing File and Directory ACEs

Describes the implications of setting access control expressions (ACEs) on files and directories.

A file [ACE](#) allows you to define access (allowlist and denylist) to files and directories for a combination of users, groups, and roles. If ACEs are not set, POSIX mode bits for the file or directory are used to grant or deny access to the file or directory.

When you set ACEs, Data Fabric software sets or resets the corresponding POSIX mode bits to match the permissions granted through ACEs. For more information, see [Setting/Modifying File and Directory ACEs](#).

- If both ACEs and POSIX mode bits are set, access is granted if access is allowed through ACEs or POSIX mode bits.
- If ACEs are not set, POSIX mode bits are used to grant access.
- If neither ACEs nor POSIX mode bits is set, access is denied.

The owner of the file or directory (and `mapr` and `root` users) can set, modify, and remove ACEs for that file or directory using `hadoop mfs` commands.

File ACEs

You can set and modify permissions to read, write, and execute files by using the `hadoop mfs` command or the [FileACE Java APIs](#) on page 2136 and [FileACE C APIs](#) on page 2136. Specifically, the following access types are supported:

Access Type		Description
Command Line	Java API (Enum)	
<code>-readfile</code>	READFILE	Read a file.
<code>-writefile</code>	WRITEFILE	Write to a file.
<code>-executefile</code>	EXECUTEFILE	Execute a file.

For more information, see [hadoop mfs](#), [FileACE Java APIs](#) on page 2136, and [FileACE C APIs](#) on page 2136.

Directory ACEs

You can set the same ACEs on directories that you set on files. In addition, directory ACEs support permissions to list, add child, delete child, and lookup directories using the `hadoop mfs` command. Specifically, the following access types are supported:

Access Type		Description
Command Line	Java API (Enum)	
<code>-readfile</code>	READFILE	Read a file.
<code>-writefile</code>	WRITEFILE	Write to a file.
<code>-executefile</code>	EXECUTEFILE	Execute a file.
<code>-readdir</code>	READDIR	List the contents of a directory. This access is required to write and/or execute files in the directory.
<code>-lookupdir</code>	LOOKUPDIR	Lookup a file in a directory. This access is required to find, read, write, and/or execute files in the directory.
<code>-addchild</code>	ADDCHILD	Add a file or subdirectory.
<code>-deletechild</code>	DELETECHILD	Delete a file or subdirectory.

Although you can set both file and directory ACEs on directories, only the directory ACEs are used for determining access to the directory. The file ACE on the directory is used as the default ACE setting for new files under that directory.

By default, when you set ACEs on a parent directory:

- Permissions for existing files and subdirectories under that parent remain unchanged.
- New files under that parent inherit the file ACEs and corresponding POSIX mode bits of the parent directory, if available. Otherwise, new files get the default ACE, the empty string (""), which indicates that no one has permissions to read, write, or execute the file. POSIX mode bits are set on the file in the traditional way.
- New subdirectories under the parent inherit both the directory and file ACEs and corresponding POSIX mode bits from the parent directory.

NOTE: When accessing files and directories, the ACEs on files have no effect on accessing the parent directory.

Workaround for Execute Operation when ACEs are set on an executable file

When ACEs are set on any file, mode bits are cleared. For a binary to execute, the kernel checks whether the execute bit is set or not, and restricts execution if it is not set. To run an executable file with ACEs set on it, use one of the following workarounds:

1. Set owner mode exec bit on binaries/shell scripts.
2. Set group mode exec bit on binaries/shell scripts.
3. Change owning group for the files to the group used in MapRAces, and set the executable group mode bit.

Setting File and Directory ACEs

Describes how to set ACEs for files and directories.

For files and directories, run the `hadoop mfs` command to set [ACEs](#). After [ACEs](#) are set, by default, the corresponding POSIX mode bits are also set. POSIX mode bits for owner and owning group are deduced by evaluating the corresponding [ACEs](#). POSIX mode bits for others is set only if "p" is given as the value for an [ACE](#).

The following table lists POSIX mode bits and corresponding access types.

	ACE	POSIX Mode Bits
File	readfile	r
	writefile	w
	executefile	x
Directory	readdir	r
	addchild	w
	deletechild	w
	lookupdir	x

The POSIX mode bit that grants write (w) access to a directory is set only if the user, role, or group is granted permission for both access types (addchild and deletechild).

The `hadoop` command, by default, sets the POSIX mode bits that correspond to the given [ACEs](#), and:

- Overwrites existing [ACE](#) values with new values, if specified, for access types that were previously set.
- Sets [ACE](#) values for access types that have not yet been set, if specified.
- Does not modify access types that are not specified with the command, regardless of how they were previously set.

WARNING: Changing the POSIX mode bits using `chmod` does not change the corresponding [ACE](#) setting and may result in different, conflicting permissions to files and directories.

File ACE Example

Illustrates setting access control expressions for files.

Suppose the following sequence of file [ACE](#) settings and corresponding POSIX mode bits are set for user u1.

As shown in the preceding illustration, in:

Step 1:

User u1 is granted permissions to read a file, sampleFile.

After the command runs, user u1 has permissions to (only) read the file. The POSIX mode bit for reading the file is set to u1 for owner/users.

There is no change in [ACEs](#) or POSIX mode bits for all other (write and execute) access types.

Step 2:

User u1 is granted permissions to write to the same file.

After the command runs, user u1 has permissions to write to the file. The POSIX mode bit for writing to the file is set to u1 for owner/users.

There is no change in [ACEs](#) or POSIX mode bits for all other (read and execute) access types.

Step 3:

User u1's permissions are modified to remove write permission (using the empty string) and to grant access to execute file.

After the command runs, user u1 has permissions to execute the file, but user u1 can no longer write to the file. The POSIX mode bit for:

- Writing to the file is set to 0 for owner/users, groups, and others.
- Executing the file is set to u1 for owner/users.

NOTE: When the empty string ("") is used to deny a specific type of file access, that type of file access is denied to all users, groups, and roles. To deny access to specific users only, use the negation operator (!).

There is no change in [ACEs](#) or POSIX mode bits for all other (read) access types.

Directory ACEs Example

Explains how to set access control expressions for directories.

For example, suppose the following diagram depicts the (command-line) sequence of directory [ACE](#) settings for user u2:

As shown in the preceding illustration, in:

Step 1:

User u2 is granted access to read directory and sampleDir, while all other directory/file [ACEs](#) are not specified.

After the command runs, user u2 has permissions to list the contents of the directory. The POSIX mode bits for listing the contents of the directory (r) is set to u2 for owner/users.

There is no change in [ACEs](#) or POSIX mode bits for all other (file- and directory-level) access types.

Step 2:

User u2 is granted permission only to add and delete child directories, while all other directory/file [ACEs](#) are not specified.

After the command runs, user u2 has permissions to create and delete child directories. The POSIX mode bit for writing (w) to the directory for owner/user is set to u2 because user u2 is granted access for both (addchild and deletechild) access types.

If user u2 creates child directories, by default, they inherit the [ACE](#) settings of the parent directory.

There is no change in [ACEs](#) or POSIX mode bits for all other (file- and directory-level) access types.

Step 3:

User u2's permissions are modified to grant access to read and write to files in the directory. User u2's permissions for adding and deleting child directories are removed (using the negation operator). All other directory/file [ACEs](#) are not specified.

After the command runs, user u2 can read and write to files in the directory, but user u2 can no longer add and delete child directories. The POSIX mode bits for directory write access (w) is set to 0 for owner/user.

Although at the directory level, user u2 has permissions to read and write to files in the directory for existing files, the file level [ACEs](#) or the POSIX mode bits for the file are used to determine access. By default, user u2 gets read and write permissions to all new files created under the directory. If user u2 creates new files under the directory, the files inherit the file [ACEs](#) from the parent directory by default, and

the POSIX mode bits for read (r) and write (w) access are set to u2 for owner/user.

There is no change in [ACEs](#) or POSIX mode bits for all other (lookupdir and executefile) access types.

Deleting File and Directory ACEs

Describes how to delete file and directory ACEs using the CLI.

You can remove all [ACE](#) associated with a file or directory using the `hadoop mfs -delace` command. After you delete all the [ACEs](#), the system sets the [ACE](#) for the file or directory to the default value, which is the empty string (""). The POSIX mode bits are not reset; if necessary, run the `chmod` command to reset POSIX mode bits.

You cannot remove specific access types that have been set. Use the empty string to deny specific types of access. After the empty string (") is used to deny a specific type of access, that type of access is denied to all users, groups, and roles. To deny access to specific users only, use the negation operator (!). If you use the empty string (") or the negation operation (!) to deny a specific type of access, the corresponding POSIX mode bit are also reset to match the [ACE](#) setting.

Managing Chunk Size

Describes the considerations for managing the chunk size for map tasks.

Files in the HPE Data Fabric filesystem are split into *chunks* (similar to Hadoop *blocks*) that are normally 256 MB by default. Any multiple of 65,536 bytes is a valid chunk size, but tuning the size correctly is important:

- Smaller chunk sizes result in larger numbers of map tasks, which can result in lower performance due to task scheduling overhead.
- Larger chunk sizes require more memory to sort the map task output, which can crash the JVM or add significant garbage collection overhead. HPE Data Fabric can deliver a single stream at upwards of 300 MB per second, making it possible to use larger chunks than in the stock Hadoop implementation. Generally, it is wise to set the chunk size between 64 MB and 256 MB.

Chunk size is set at the directory level. Files inherit the chunk size settings of the directory that contains them, as do subdirectories on which chunk size has not been explicitly set. Any files written by a Hadoop application, whether using the file APIs or over NFS for the HPE Data Fabric, use chunk size specified by the settings for the directory where the file is written. If you change a directory's chunk size settings after writing a file, the file will keep the old chunk size settings. Further writes to the file will use the file's current chunk size.

NOTE: If chunk size is zero (0), when an application makes a request for block size, HPE Data Fabric will return 1073741824 (1GB); however, `hadoop mfs` on page 7489 commands will continue to display 0 for chunk size.

Configuring Chunk Size

Chunk size also affects parallel processing and random disk I/O during MapReduce applications. A higher chunk size means less parallel processing because there are fewer map inputs, and therefore fewer mappers. A lower chunk size improves parallelism, but results in higher random disk I/O during shuffle because there are more map outputs. Set the `io.sort.mb` parameter to a value between 120% and 150% of the chunk size.

Here are the general guidelines for chunk size:

- For most purposes, set the chunk size to the default 256 MB and set the value of the `io.sort.mb` parameter to the default 380 MB.

- On very small clusters or nodes with not much RAM, set the chunk size to 128 MB and set the value of the `io.sort.mb` parameter to 190 MB.
- If application-level compression is in use, the `io.sort.mb` parameter should be at least 380 MB.

NOTE: If you have Drill running in the cluster, change the `store.parquet.block-size` parameter in Drill so that the Parquet block size is the same as the chunk size in the HPE Data Fabric filesystem. See [Configuring the Parquet Block Size](#) for more information.

Setting Chunk Size

You can set the chunk size for a given directory in two ways:

- Change the `ChunkSize` attribute in the `.dfs_attributes` file at the top level of the directory
- Use the command `hadoop mfs -setchunksize <size> <directory>`

For example, if the volume `test` is NFS-mounted at `/mapr/my.cluster.com/projects/test` you can set the chunk size to 268,435,456 bytes by editing the file `/mapr/my.cluster.com/projects/test/.dfs_attributes` and setting `ChunkSize=268435456`. To accomplish the same thing from the `hadoop` shell, use the following command:

```
hadoop mfs -setchunksize 268435456 /mapr/my.cluster.com/projects/test
```

Managing Compression

Lists the advantages of using compression.

Data Fabric provides compression for files stored in the cluster. Compression is applied automatically to uncompressed files unless you turn compression off. The advantages of compression are:

- Compressed data uses less bandwidth on the network than uncompressed data.
- Compressed data uses less disk space.

Choosing a Compression Setting

Lists the compression algorithms supported by Data Fabric.

Data Fabric supports three different compression algorithms:

- lz4 (default)
- lzf
- zlib

Compression algorithms can be evaluated for compression ratio (higher compression means less disk space used), compression speed and decompression speed. The following table gives a comparison for the three supported algorithms. The data is based on a single-thread, Core 2 Duo at 3 GHz.

Compression Type	Compression Ratio	Compression Speed	Decompression Speed
lz4	2.084	330 MB/s	915 MB/s
lzf	2.076	197 MB/s	465 MB/s
zlib	3.095	14 MB/s	210 MB/s

Note that compression speed depends on various factors including:

- block size (the smaller the block size, the faster the compression speed)
- single-thread vs. multi-thread system
- single-core vs. multi-core system
- the type of codec used

Setting Compression on Files

Compression is set at the directory level. Any files written by a Hadoop application, whether via the file APIs or over NFS, are compressed according to the settings for the directory where the file is written. Sub-directories on which compression has not been explicitly set inherit the compression settings of the directory that contains them.

If you change a directory's compression settings after writing a file, the file will keep the old compression settings—that is, if you write a file in an uncompressed directory and then turn compression on, the file does not automatically end up compressed, and vice versa. Further writes to the file will use the file's existing compression setting.

WARNING: Only the owner of a directory can change its compression settings or other attributes. Write permission is not sufficient.

File Extensions of Compressed Files

Lists extensions of compressed files.

By default, HPE Data Fabric does not compress files whose filename extensions indicate they are already compressed. The default list of filename extensions is as follows:

- bz2
- gz
- lzo
- snappy
- tgz
- tbz2
- zip
- z
- Z
- mp3
- jpg
- jpeg
- mpg
- mpeg
- avi

- gif
- png
- jar

The list of filename extensions not to compress is stored as comma-separated values in the `mapr.fs.nocompression` configuration parameter and can be modified with the `config save` command. For example, you can add `parquet` to the default list:

```
maprcli config save -values
'{"mapr.fs.nocompression":"bz2,gz,lzo,snappy,tgz,tbz2,zip,z,Z,mp3, \
jpg,jpeg,mpg,mpeg,avi,gif,png,parquet"}'
```

The list can be viewed with the `config load` command. Example:

```
maprcli config load -keys mapr.fs.nocompression
```

NOTE: The filename extensions given in the default list of filename extensions are case-sensitive. For example, Data Fabric compresses a file with the extension `.JPG`, even if `.jpg` files are not to be compressed, by default. If you do not want the files in the file system with the `.JPG` extension to be compressed, add `JPG` to the list of filename extensions for the `mapr.fs.nocompression` configuration parameter.

Turning Compression On or Off on Directories Using the CLI

Explains how to turn off or turn on compression and optionally specify an algorithm, using the command line.

You can turn compression on or off for a given directory in two ways:

- Set the value of the Compression attribute in the `.dfs_attributes` file at the top level of the directory.
 - Set `Compression=lzf|lz4|zlib` to turn compression *on* for a directory.
 - Set `Compression=false` to turn compression *off* for a directory.
- Use the command `hadoop mfs -setcompression on|off|lzf|lz4|zlib <dir|table>`.

If you choose `-setcompression on` without specifying an algorithm, `lz4` is used by default. This algorithm has improved compression speeds for HPE Data Fabric's block size of 64 KB.

The symbols for the various compression settings are explained here:

Symbol	Compression Setting
Z	lz4
z	zlib
L	lzf
U	Uncompressed, or previously compressed by another algorithm

Example

Suppose the volume `test` is NFS-mounted at `/mapr/my.cluster.com/projects/test`. You can turn off compression by editing the file `/mapr/my.cluster.com/projects/test/.dfs_attributes` and

setting `Compression=false`. To accomplish the same thing from the hadoop shell, use the following command:

```
hadoop mfs -setcompression off /projects/test
```

You can view the compression settings for directories using the `hadoop mfs -ls` command. For example,

```

```

Suppose three directories `abc`, `klm`, and `xyz`. You can turn on compression and set different compression algorithm for the directories by running the following commands:

```
hadoop mfs -setcompression on /ksTestVol1/abc
hadoop mfs -setcompression lzf /ksTestVol1/klm
hadoop mfs -setcompression zlib /ksTestVol1/xyz
```

You can then view the compression settings for the directories using the `hadoop mfs -ls` command. For example:

```
hadoop mfs -ls /ksTestVol1/
Found 3 items
drwxr-xr-x  Z U U    - root root          0 2017-12-11 08:41 268435456 /

```

Setting Compression During Shuffle

By default, MapReduce uses compression during the Shuffle phase. You can use the `-Dmapreduce.maprfs.use.compression` switch to turn compression *off* during the Shuffle phase of a MapReduce job. For example:

```
hadoop jar xxx.jar -Dmapreduce.maprfs.use.compression=false
```

Managing Hard Links

Explains what hard links are, and their limitations.

A hard link is a directory entry that associates a name with a file (or physical data) on the filesystem. Hard links allow multiple names to be associated with the same data (and associated inode) from within or outside of a directory. Every time a hard link is created, a directory entry is created and the inode (associated with the directory entry) remains the same across all hard links associated with that data. That is, all names associated with the data point to the same inode.

The following diagram illustrates the hard link semantics. Here, directory entries in dirA, dirB, and dirC for file names name1, name2, and name3 respectively all point to the inode 12345, which contains metadata including the text in the file and a count of the number of hard links to the file (or physical data).

In contrast, when a symbolic link is created, a new inode is created and the text part of the inode (associated with the symlink file) contains the path to the actual file. The following diagram illustrates the symbolic link semantics. Here, the directory entry in dirA for file name, name1, is associated with inode 12345, which contains the text in the file. The directory entry in dirB for symbolic link file, name2, is associated with inode 13579, which contains the path to file in dirA (`/dirA/name1`). Deleting the file, name1, in dirA will result in the symlink file in dirB, name2, pointing to stale content, which in turn will return errors when accessed.

Hard links can be created on regular files, symlink files, device files, and tables.

Limitations

- Hard links cannot be created on directories.
- Hard links cannot be created across volumes or clusters. Instead, use symbolic link to link to a file on a different volume.
- Hard links within a volume are carried over to mirror volumes and volume snapshots. During cross-mirroring, there will be an error if support for hardlinks is not enabled on both the clusters.
- The `hadoop distcp` command cannot be used for creating and preserving copies of hard links.
- The maximum number of hard links is constrained by the integer width (32 bits), which means the maximum number possible for a file is 2^{32} .

Usage

Any user with access to the directory can create a hard link to any file under that directory. To create hard links, the user must have write permissions on the directory and execute permissions (to do the lookup for the path) on the target file. To read or modify the file, the user must have read or write permissions respectively on the file.

Errors

For information on the type of failures and errors, refer to the [man page](#). In addition, please note that the EXDEV error is returned if command is run to create cross-volume or cross-cluster hard links.

Enabling Hard Links

By default, this feature is enabled on all new installation. If you upgrade, you must enable this feature. To enable this feature, run the following command:

```
maprcli cluster feature enable -name mfs.feature.hardlinks.support
```

Setting a Hard Link

Explains how to create a hardlink to a file.

To set a hard link using:

- POSIX loopbacknfs client or NFS client, run the following command:

```
ln <sourcefile> <newfile>
```

where <sourcefile> is the name of the file to link to and <newfile> is the name of the hard link, which must *not* already be present.

- Hadoop, run the following command:

```
hadoop mfs -lnh <sourcefile> <newfile>
```

where <sourcefile> is the name of the file (including full path) to link to and <newfile> is the name of the hard link (including the full path). When running this command, specify the full path to both files.

Retrieving the Number of Hard Links

Explains how to retrieve the number of hard links to a file.

To retrieve the number of hard links associated with a file, run the following command:

```
ls -l
```

The command, `ls -l`, will print the number of hardlinks in the second column. For example, your output will look similar to the following:

```
ls -l sample-link
-rw-r--r- 2 root root 0 Apr 21 11:09 sample-link
```

To retrieve the list of the hard links associated with a file, run the following command:

```
find <dirpath> -samefile <sourcefile>
```

where <dirpath> is the path to the source file and <sourcefile> is the source file for the hard link. For example, your output will look similar to the following:

```
find . -samefile file8
./file8-link2
./file8-link100
./file8-link101
./file8
./file8-link
```

For POSIX (loopback NFS for the HPE Data Fabric) clients, the number of hardlinks to a file can be retrieved using the `stat64` system call. For example, your output will look similar to the following:

```
stat samplefile
File: 'samplefile'
Size: 0          Blocks: 0          IO Block: 131072 regular empty
file
Device: 14h/20d Inode: 853785146  Links: 4
Access: (0644/-rw-r--r--)  Uid: (  0/   root)   Gid: (  0/   root)
Access: 2016-05-12 13:06:21.000000000 -0700
Modify: 2016-05-12 13:06:30.002560000 -0700
Change: 2016-05-12 13:06:30.002560000 -0700
```

If you are not using NFS for the HPE Data Fabric or the POSIX clients, to retrieve the number of hard links, you can run the `hadoop` command to retrieve the `fid` and then run the `maprccli` command to retrieve the number of hard links as follows. The `nlink` variable will print the number of links.

```
hadoop mfs -ls /p1
Found 1 items
-rw-r--r--  Z U U   3 root root          3054 2016-05-05 13:49  268435456 /p1
p 2049.40.262550  node-31.lab:5660

maprccli fid stat -fid 2049.40.262550
  xattrInum  uid  atime          nblocks  deleteFlags      mtime
parent      nlink type          version  size  mode  networkencryption
subtype    gid  compression
  0          0      1462481255    1          DeleteTypeNone  1462481376

FSTInval   0      lz4
```

Removing Hard Links

To remove a hard link using:

- Linux, run the following command:

```
rm -f <hard link>
```

- Hadoop, run the following command:

```
hadoop fs -rm <path to hard link>
```

Example

For example, suppose there are 4 hard links to file `cite75_99.txt`.

```
$ ls -l
total 1289433
-rwxr-xr-x 5 root root 264075431 Jul 28 13:46 cite75_99.txt
-rwxr-xr-x 5 root root 264075431 Jul 28 13:46 cite-link1
-rwxr-xr-x 5 root root 264075431 Jul 28 13:46 cite-link2
-rwxr-xr-x 5 root root 264075431 Jul 28 13:46 cite-link3
-rwxr-xr-x 5 root root 264075431 Jul 28 13:46 cite-link4

$ maprccli fid stat -fid 2142.34.131274
parent      deleteFlags  atime          gid  nlink  type          mtime
version  mode  uid  xattrInum  size          subtype  networkencryption
nblocks  compression
2142.16.2  DeleteTypeNone  1469738740  0      5      FTRegular    1469738771
1048600   755   0      0          264075431  FSTInval   false
8          lz4
```

To remove a hard link using:

- Linux, run the following command:

```
rm -f cite-link1
```

To verify that the command ran successfully, run the following command:

```
$ ls -l
total 1031546
-rwxr-xr-x 4 root root 264075431 Jul 28 13:46 cite75_99.txt
-rwxr-xr-x 4 root root 264075431 Jul 28 13:46 cite-link2
-rwxr-xr-x 4 root root 264075431 Jul 28 13:46 cite-link3
-rwxr-xr-x 4 root root 264075431 Jul 28 13:46 cite-link4
```

- Hadoop, run the following command:

```
$ hadoop fs -rm /test-hl/cite-link2
16/07/28 13:52:00 INFO Configuration.deprecation: io.bytes.per.checksum
is deprecated. Instead, use dfs.bytes-per-checksum
16/07/28 13:52:00 INFO fs.TrashPolicyDefault: Namenode trash
configuration: Deletion interval = 0 minutes, Emptier interval = 0
minutes.
Deleted /test-hl/cite-link2
```

To verify that the command ran successfully, run the following command:

```
$ maprcli fid stat -fid 2142.34.131274
parent deleteFlags atime gid nlink type mtime
version mode uid xattrInum size subtype networkencryption

Managing Extended Attributes

Describes what extended attributes are, and the POSIX permissions that you need to manage them.

Extended attributes (referred to as `xattr`s) allow user applications to associate additional metadata with a regular file or directory. Unlike system-level inode metadata, such as file permissions or modification time, extended attributes are not interpreted by the system but are instead used by applications to store additional information about an inode. Multiple extended attributes can be associated with a single inode. The maximum size allowed for an extended attribute is 64 KB.

An extended attribute is a name-value pair, with a string name and binary value. The extended attribute names are prefixed with a namespace. For example, an `xattr` named `myXattr` in the user namespace would be specified as `user.myXattr`.

Limitations

- For the five valid namespaces supported by HDFS, HPE Data Fabric supports the following:

Namespace	HPE Data Fabric Functionality
user	Commonly used by client applications. Access to these extended attributes in the user namespace is controlled by corresponding file/directory permissions. For more information, see Permissions for Extended Attributes .

Namespace	HPE Data Fabric Functionality
trusted	Available to superusers only. Access is denied for all other users. The extended attribute is not available through userspace methods.

NOTE: HPE Data Fabric does not support the raw namespace.

- Extended attributes cannot be associated with symbolic links. If extended attributes are used on symbolic links, they are instead applied to the symbolic link target file.
- The preserve options of commands like `cp -px` and `distcp -px` will work on extended attributes only in the following cases:
 - With Hadoop commands such as `hadoop fs`.
 - On FUSE mounted file paths.

NOTE: Extended attributes are not supported on NFS for the HPE Data Fabric file paths.

Permissions for Extended Attributes

The following table lists the permissions (POSIX mode bits or [ACEs](#)) you will need to set, retrieve, or modify extended attributes.

To...	For directories, you need...	For files, you need...
Set extended attributes	Mode bits: write (OR) ACE : addchild	Mode bits: write (OR) ACE : writefile
Remove extended attributes	Mode bits: write (OR) ACE : deletechild	Mode bits: write (OR) ACE : writefile
Retrieve extended attributes	Mode bits: read (OR) ACE : readdir	Mode bits: read (OR) ACE : readfile

Enabling Extended Attributes

Extended attributes are enabled by default on all new installation. If you are upgrading, this feature must be explicitly enabled. To enable, run the following command:

```
maprcli cluster feature enable -name mfs.feature.fileace.support
```

Setting, Retrieving, and Removing Extended Attributes

You can set and retrieve extended attributes on files, directories, and FUSE mounted file path using [Hadoop](#) commands, [Linux](#) commands, and [Java APIs](#).

Hadoop Commands for Extended Attributes

Lists the Hadoop commands to set, retrieve, and remove extended attributes on files, directories and FUSE mounted paths.

You can set, retrieve, and remove extended attributes on files, directories, and FUSE mounted file path using the [hadoop fs](#) command. When setting an extended attribute:

- The name must be prefixed with a namespace.
- The extended attribute value must be encoded as one of the following:

text	The given string must be enclosed in double quotes to be treated as text.
hex	The given string must begin with 0x or 0X to be treated as hexadecimal number.
base64	The given string must begin with 0s or 0S to be treated as base64 encoding.

NOTE: You must have the right permissions to set, retrieve, and/or remove extended attributes.

Set Extended Attributes

To set an extended attribute name and value for a file or directory, run the following command:

```
hadoop fs -setfattr -n name [-v value] <path>
```

For example:

```
hadoop fs -setfattr -n system.name -v system-hadoopfs /volforsnap/
smallfile.txt
hadoop fs -setfattr -n user.name -v user-hadoopfs /volforsnap/smallfile.txt
hadoop fs -setfattr -n security.name -v security-hadoopfs /volforsnap/
smallfile.txt
hadoop fs -setfattr -n trusted.name -v trusted-hadoopfs /volforsnap/
smallfile.txt
```

Retrieve Extended Attributes

To retrieve the extended attributes associated with a file or directory, run the following command:

```
hadoop fs -getfattr [-R] -n name | -d [-e en] <path>
```

For example:

```
hadoop fs -getfattr -d /volforsnap/smallfile.txt
SLF4J: Class path contains multiple SLF4J bindings.
SLF4J: Found binding
in [jar:file:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/common/lib/
slf4j-log4j12-1.7.10.jar!/org/slf4j/impl/StaticLoggerBinder.class]
SLF4J: Found binding in [jar:file:/opt/mapr/lib/
slf4j-log4j12-1.7.12.jar!/org/slf4j/impl/StaticLoggerBinder.class]
SLF4J: See http://www.slf4j.org/codes.html#multiple_bindings for an
explanation.
SLF4J: Actual binding is of type [org.slf4j.impl.Log4jLoggerFactory]
# file: /volforsnap/smallfile.txt
system.name="system-hadoopfs"
trusted.name="trusted-hadoopfs"
security.name="security-hadoopfs"
user.name="user-hadoopfs"
```

Remove Extended Attributes

To remove an extended attribute by name, run the following command:

```
hadoop fs -setfattr -x name <path>
```

For example:

```
hadoop fs -setfattr -x user.key1 /xattrs/m7user1/dir1
```

Linux Commands for Extended Attributes

You can set, retrieve, restore, and remove extended attributes on files, directories, and FUSE mounted file paths using Linux commands. For more information, refer to the respective Linux man page.

To use extended attributes on files on a MapR cluster with a FUSE client mounted path, see [Configuring the HPE Data Fabric FUSE-Based POSIX Client](#) on page 1876 to enable extended attributes through FUSE client.

Set Extended Attributes

To set an extended attribute name and value on a file/directory and/or a FUSE mounted file path, run the following command:

```
setfattr [-h] -n name [-v value] pathname...
```

For example:

```
setfattr -n system.name -v system /mapr_fuse/testcluster/volforsnap/
smallfile.txt
setfattr -n security.name -v test /mapr_fuse/testcluster/volforsnap/
smallfile.txt
setfattr -n trusted.name -v trusted /mapr_fuse/testcluster/volforsnap/
smallfile.txt
setfattr -n user.name -v user /mapr_fuse/testcluster/volforsnap/
smallfile.txt
```

For more information, refer to the Linux [man page](#).

Retrieve Extended Attributes

To retrieve extended attributes, run one of the following commands:

```
getfattr [-hRLP] -n name [-e en] pathname...
getfattr [-hRLP] -d [-e en] [-m pattern] pathname...
```

For example:

```
getfattr -d -m - /mapr_fuse/testcluster/volforsnap/smallfile.txt
getfattr: Removing leading '/' from absolute path names
file: mapr_fuse/testcluster/volforsnap/smallfile.txt
security.name="test"
system.name="system"
trusted.name="trusted"
user.name="user"
```

For more information, refer to the Linux [man page](#).

Remove Extended Attributes

To remove an extended attribute by name, run the following command:

```
setfattr [-h] -x name pathname...
```

For example:

```
setfattr -x user.test test2
```

For more information, refer to the Linux [man page](#).

Restore Extended Attributes

To restore extended attributes from a file, which must be in the format generated by the `getfattr` command with the `--dump` option, run the following command:

```
setfattr [-h] --restore=file...
```

For example:

```
setfattr --restore=testout
getfattr -d test2
file: test2
user.test="test"
```

For more information, refer to the Linux [man page](#).

Java APIs for Extended Attributes

Java APIs to manage extended attributes

You can set, retrieve, and remove extended attributes on files, directories, and FUSE mounted file path using [Extended Attribute Java APIs](#).

Set Extended Attributes

To set extended attributes, use the following APIs:

```
public void setXAttr(Path path, String name, byte[] value) throws IOException
```

Set an extended attribute on a file or directory. The name must be prefixed with the namespace followed by ". ". For example, "user.attr". By default, if a given extended attribute exists, then it will be replaced with the specified attribute.

```
public void setXAttr(Path path, String name, byte[] value, Enum<SetXAttrSetFlag> flag) throws IOException
```

Set an extended attribute on a file or directory. The name must be prefixed with the namespace followed by ". ". For example, "user.attr". The `XAttrSetFlag` value can be:

- **CREATE** to create a new extended attribute. An error is returned if an extended attribute with the given name already exists.
- **REPLACE** to replace an existing extended attribute. An error is returned if the specified extended attribute does not already exist.

Retrieve Extended Attributes

To retrieve extended attributes, use the following APIs:

```
public byte[] getXAttr(Path path, String name) throws IOException
```

Get an extended attribute name and value for a file or directory. The name must be prefixed with the namespace followed by ". ". For example, "user.attr".

<code>public Map<String,byte[]> getXAttrs(Path path) throws IOException</code>	Get all the extended attribute name/value pairs for a file or directory. Only those extended attributes that the logged-in user has permissions to view, are returned.
<code>public Map<String,byte[]> getXAttrs(Path path, List<String> names) throws IOException</code>	Get the extended attributes specified by the given list of names. Only those extended attributes that the logged-in user has permissions to view, are returned.
<code>public List<String> listXAttrs(Path path) throws IOException</code>	Get all the extended attribute names for a file or directory. Only those extended attribute names that the logged-in user has permissions to view, are returned.

Remove Extended Attributes

To remove an extended attribute associated with a file or directory, use the following API:

<code>public void removeXAttr(Path path, String name) throws IOException</code>	Remove an extended attribute of a file or directory. The name must be prefixed with the namespace followed by ".". For example, "user.attr".
--	--

Managing Core Files

Describes how to set the location for core files.

The Linux `core_pattern` file (in `/proc/sys/kernel/core_pattern`) can be used to specify the location for storing core files. If any process launched by HPE Data Fabric crashes, the core files are created in the directory specified by the `core_pattern` file. A valid location in the `core_pattern` file is a full path to the directory you want to use. For example:

```
/tmp/dir1/cores/%e.core.%p.%h
```

TIP: For details about the standard Linux % specifiers that you can use to name core files, see the [core man page](#).

If the `core_pattern` file is empty, if the file does not contain a full path, or if it uses the "|" redirection feature, by default, HPE Data Fabric sets the location for core files (in the event of a core dump on a node) to `/opt/cores` directory when:

- The `configure.sh` utility is run.
- The Warden init script is run.
- The file system init script is run by Warden.

The default directory (`/opt/cores`) is also used if the `core_pattern` file contains the default HPE Data Fabric value for core files.

For HPE Data Fabric software, the directory being used to store core files should not be used for other purposes and should be empty. The `cores` directory cannot be the home directory, as it can cause problems during SSH access. The `hoststats` service monitors the directory specified in the `core_pattern` file and raises the node-level [alarm](#) if the directory contains any entry other than "." and "..". When Warden is started, sticky bit is set on the `cores` directory.

Managing Tiered Files from the Command-line

After creating a tiered volume and associating a tier with the volume, you can manually trigger offload and recall of individual files in the volume using the CLI. This section describes how to offload file to and recall file from the tier, retrieve status of a file-level tiering operation, and how to perform certain tiering operations when `hadoop` and `maprccli` are not available on the host you wish to use for triggering the tiering operation.

Offloading a File to a Tier Using the CLI and REST API

Describes how to offload files to a tier using the CLI and the REST API.

About this task

Files, in tiering-enabled volumes, can be offloaded individually using the CLI and REST API. See [Data Offload and Purge](#) on page 580 for more information. For information on offloading files using (loopbacknfs or FUSE-based) POSIX or NFS clients when `maprccli` or `hadoop` commands are not available, see [Running Tiering Commands when maprccli and hadoop Commands are not Available](#) on page 1604.

NOTE: Offloading a single file to a warm-tier might result in wasted space. See [Data Offload and Purge](#) on page 580 for more information

The user offloading the file data must have write permission (mode bit or [ACE](#)) on the file to offload data.

You can also offload all data in a tiering-enabled volume to the associated tier. see [Offloading a Volume to a Tier](#) on page 1515 for more information.

CLI

Run one of the following commands to offload file data to a tier:

- `hadoop mfs -offload <file-path>`

For more information, see [hadoop mfs](#) on page 7489.

- `/opt/mapr/bin/maprccli file offload -name <file>`

For more information, see [file offload](#) on page 2492.

REST API

Send a request of type POST. For example:

```
curl -k -X
POST 'https://abc.sj.us:8443/rest/
file/offload?name=fileName' --user
mapr:mapr
```

If the manual offload succeeds, the command returns nothing. If the offload fails, the command returns an error code. For more information on the codes, see [Retrying Failed Operation](#) on page 1521.

Recalling a File to file system Using the CLI and REST API

About this task

You can recall individual files from a storage tier. When you recall a file, the MAST Gateway fetches a copy of the data to the cluster. Based on the expiration time setting on the volume, recalled data is automatically:

- Offloaded again based on the storage policy (rules) if there are changes to the recalled data.
- Purged when the compactor runs if there are no changes to the recalled data.

See [Data Reads, Writes, and Recalls](#) on page 587 for more information.

NOTE: You can recall all data from the tier to the volume. See [Recalling a Volume to file system](#) on page 1519 for more information.

Recalling a File Manually Using the CLI

Procedure

- Run one of the following commands to recall a file:

- `hadoop mfs -recall <pathToFile>`

For more information, see [hadoop mfs](#) on page 7489.

- `maprccli file recall -name <pathToFile>`

For more information, see [file recall](#) on page 2493.

NOTE: For information on recalling files using (loopbacknfs or FUSE-based) POSIX or NFS clients when maprccli or hadoop commands are not available, see [Running Tiering Commands when maprccli and hadoop Commands are not Available](#) on page 1604.

Recalling a File Using the REST API

Procedure

- Send a request of type POST to the URL. For example, send a request similar to the following:

```
curl -k -X POST 'https://abc.sj.us/rest/file/recall?name=fileName' --user
mapr:mapr
```

Terminating a Running File-Level Tiering Job

Explains how to terminate file tiering jobs using the Control System and the CLI.

About this task

You can terminate an ongoing offload or recall of a file using the CLI. Terminating a running:

- Offload operation does not prevent future offloads; if a schedule is associated with the volume, data that is still on the cluster is automatically offloaded based on the rules as per schedule. You can also manually offload data again at any time by running the [file offload](#) on page 2492 or [hadoop mfs](#) on page 7489 command.
- Recall operation does not prevent future recalls; you can run the recall command again to recall the remaining data on the tier. Based on the expiry time set on the volume (associated with the recalled data), recalled data is offloaded if there are changes or purged if there are no changes. See [Recalling a Volume to file system](#) on page 1519 for more information.

For information on terminating a running offload or recall operation using (loopbacknfs or FUSE-based) POSIX or NFS clients when maprccli or hadoop commands are not available, see [Running Tiering Commands when maprccli and hadoop Commands are not Available](#) on page 1604. For information on terminating a running volume-level job, see [Terminating a Running Volume-Level Tiering Job](#) on page 1520.

Terminating a Running File-Level Offload or Recall Operation Using the CLI and REST API

About this task

CLI

Run the following command to terminate a currently running file-level offload or recall operation:

```
maprccli file tierjobterminate -name <filePath>
```

For more information, see [file tierjobterminate](#) on page 2494.

REST API

Send a request of type POST. For example:

```
curl -X POST 'https://<host>:8443/rest/file/tierjobterminate?name=<filePath>' --user <username>:<password>
```

Running Tiering Commands when maprccli and hadoop Commands are not Available

You can offload and/or recall a file with NFS, loopbacknfs, and FUSE-based POSIX clients even if [maprccli](#) or [hadoop](#) commands are not available. To perform file-level data tiering operations like offload and/or recall using NFS, loopbacknfs, and FUSE-based POSIX clients when [maprccli](#) or [hadoop](#) commands are not available, after mounting, provide the tiering command such as offload, recall, tierjobstatus, and/or tierjobabort as described below. When you run the command, the command creates a hidden .tier_attributes file (similar to .dfs_attributes file) that is purged immediately after the operation is submitted to the server.

 **NOTE:** When you run the command, the tiering command is triggered immediately and storage policy (or rule), if any, at the volume-level is ignored.

Usage

```
/bin/echo "<command> <file-name>" > .tier_attributes
```

 **NOTE:** Do not use echo in the terminal; instead, use /bin/echo.

Options

Option	Description
command	The tiering related command to run. The following commands are supported: <ul style="list-style-type: none">• offload• recall• tierjobstatus• tierjobabort
file-name	The name of the file.

Return Values

On success, the command returns nothing. Otherwise, the command returns one of the following `/bin/echo` return codes, which are displayed as write errors:

Code	Message	Description
EEXIST	File exists	Indicates tier job is queued or is already in progress.
ENOTEMPTY	Directory not empty	Indicates that tier job queue is full.
ENOENT	No such file or directory	Indicates that the specified file or job ID does not exist.
EIO	I/O error	Indicates that the job could not be submitted. Run the <code>tierjobstatus</code> command to determine the reason for this error.
EINVAL	Invalid argument	Indicates that the given command is invalid or not available. See Options on page 1604 for the list of supported commands.

Examples

Offload file named test

```
# /bin/echo "offload test"
> .tier_attributes
/bin/echo: write error: File exists
```

Recall a file named test

```
# /bin/echo "recall test"
> .tier_attributes
/bin/echo: write error: File exists
```

Check the status of a running job for a file

```
# /bin/echo "tierjobstatus test"
> .tier_attributes
```

Abort a running job

```
# /bin/echo "tierjobabort test"
> .tier_attributes
/bin/echo: write error: No such file
or directory
```

Retrieving Status of File-level Tiering Operation and File Data

About this task

You can retrieve the status of a file-level tiering operation using the CLI and REST API. For information on volume-level tiering operation, see [Retrieving the Status of a Volume-level Tiering Operation](#) on page 1525.

Retrieving the Status of a Running Tiering Operation

Procedure

- Run the `maprcli` command or send a request of type GET to check the status of an active or completed offload, abort, and/or recall operation.
See [file tierjobstatus](#) on page 2496 for more information. For example:

CLI

```
maprcli file tierjobstatus -name
<file_name> -json
```

REST

```
curl -X
GET 'https://<host>:8443/rest/file/
tierstatus?name<file_name>' --user
<username>:<password>
```

See [Output](#) on page 2496 for more information.

Retrieving Status of File Data**Procedure**

- Run the maprcli command or send a request of type GET to determine the status of file data. See [file tierstatus](#) on page 2509 for more information. For example:

CLI

```
maprcli file tierstatus -name
<file_name>
```

REST

```
curl -X
GET 'https://<host>:8443/rest/file/
tierstatus?name=<file_name>' --user
<username>:<password>
```

See [Output](#) on page 2510 for more information.

Administering Tables

Administration of the HPE Data Fabric Database is done primarily via the command line (maprcli) or with the Managed Control System (MCS). Regardless of whether the HPE Data Fabric Database table is used for binary files or JSON documents, the same types of commands are used with slightly different parameter options. HPE Data Fabric Database administration is associated with tables, columns and column families, and table regions.

Why use HPE Data Fabric Database?

From an administrator's point-of-view, HPE Data Fabric Database provides the following capabilities:

- Minimal administration:** Single namespace for files, tables and streams, flexible schema that allows built-in data management and protection, automatic splits and merges as data grows and shrinks, and easy bulk data loading.
- Self-healing from HW and SW failures:** Replicated state and data for instant recovery and automated re-replication of data.
- Global low-latency replication:** Multi-master (that is, active to active) replication which is important for disaster recovery. Includes reduced risk of data loss, application failover, and faster data access.
- High performance and low latency:** Integrated system with fewer software layers, single hop to data, and no compactions with low I/O amplification.

- **Fine-grained security:** Access permissions can be granted to tables (as well as files and streams) at a granular level using [Access Control Expressions \(ACEs\)](#), which are designed for flexibility and ease-of-use.

How Do I Get Started?

The following graphic shows the basics steps (with hotspot links) for getting started.

1. [Install MapR](#)
2. [Creating a table for bulkloading data involves specifying the table type \(JSON or binary\) and setting the bulkload flag.](#)
3. [Bulkloading can be done either as a full or incremental bulkload. Different utilities are used for the bulk load depending on what you are trying to accomplish.](#)
4. [Both full and incremental bulkloads can be performed for HPE Data Fabric Database JSON tables. This topic describes the three command-line utilities available for loading documents into JSON tables.](#)
5. [Administration of tables describes how to create, read, update, and delete tables as well as other tasks such as managing permissions and auditing.](#)
6. [This section cover the administration of column families including how to create column families, alter them, delete them, set permissions on them, and set and display parameter values.](#)
7. [This topic describes administrative tasks associated with table regions including how to set autosplitting.](#)

Useful Administrator Resources

Links to Resources	Descriptions
maprccli and REST API Syntax on page 2266	Command line reference for Data Fabric operations. For HPE Data Fabric Database, the commands particularly applicable are associate with the <code>maprccli table</code> on page 2753 command. These commands include not only table CRUD operations but also table column family, table region, and table replication operations.
Utilities for HPE Data Fabric Database JSON Tables on page 7428	Utilities for HPE Data Fabric Database JSON tables. These utilities are used form managing JSON tables including importing and exporting data to and from JSON tables. Particularly useful are: <ul style="list-style-type: none"> • HPE Data Fabric Database JSON ImportJSON on page 7438 utility with imports JSON documents into a HPE Data Fabric Database JSON table. • HPE Data Fabric Database Shell (JSON Tables) on page 7401utility which performs CRUD operations on JSON documents and tables.

Links to Resources	Descriptions
Utilities for HPE Data Fabric Database Binary Tables on page 7446	Utilities for HPE Data Fabric Database binary tables. These utilities are used for managing binary tables. Particularly useful is HPE Data Fabric Database Binary CopyTable on page 7446 which is used to copy data from one HPE Data Fabric Database binary table to another.  NOTE: To import HFile or Result files in a HPE Data Fabric Database binary table, the hbase command can be used. See Loading Data into Binary Tables on page 1650.
Configuring Security on page 2044	Information on security tasks for configuring Data Fabric security, managing secure clusters, and administering auditing.
Hadoop and Big Data Security	Data Fabric information on Security and Big Data Governance that identified key unique advantages including authentication, authorization, auditing, and encryption.
Provisioning Secure Access Controls in HPE Data Fabric Database	Blog discussing Data Fabric's boolean Access Control Expressions (ACEs) which provide granular-level permissions including topics and examples of best practices.

Managing Tables

HPE Data Fabric Database supports two types of table: binary tables and JSON tables. This section covers how to create, edit, and delete tables, as well as how to set parameter values, display parameter values, grant permissions and access, replicate tables, and more using the Control System and the CLI.

After you log in to the Control System and click **Data > Table**, the **Tables** page displays the following in the various panes:

- **Active Alarms** — The active table (replication) alarms
- **Recently Viewed Tables** — The tables that were most recently accessed from the Control System
- List of volumes that you have access to and a search field to retrieve a table by table path

Click **Create Table** button to create a new binary or JSON table.

Creating a New Table

Explains how to create both binary tables and JSON tables using either the Control System, the CLI, or the REST API.

About this task

Different methods can be used to create HPE Data Fabric Database tables, such as maprccli, hbase shell, mapr dbshell commands, and the Control System. The following procedures describe how to create tables using these methods.

Creating a Table Using the Control System

Procedure

1. Log into the Control System using your login credentials. The Control System **Overview** page appears.

NOTE: This option is not available on the Kubernetes version of the Control System.

2. Click **Data > Tables** from the top of the page. The **Tables** page appears.

3. Click **Create Table**. The **Create New Table** page appears.

4. From the **Properties** pane of the **Create New Table** page, choose the table type:

- JSON

NOTE: You must select **JSON** for the table type to enable dynamic data masking.

- Binary

5. Specify values for fields displayed under **Properties** pane of the **Create New Table** page, as appropriate:

a) Enter the path to or location for the table in the **Table Path** field.

Tables are stored in the Data Fabric file system. When providing the path to a table, use these conventions:

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` in `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customer`

b) Select the interval of time to apply for logging table metrics in the **Metric Interval** field.

You can choose to log metrics every 10 seconds, 1 minute (default), or 10 minutes. For more information on visualizing the metrics, see *Visualizing Table Metrics in the Control System*.

c) Enable (**Yes**) or disable (**No**) auto-splitting of table.

If enabled, the table is split automatically into regions as the table grows. If disabled, the table can be split manually into regions. By default, this option is enabled.

d) Choose whether to complete a full bulk load or incremental bulk load of the table.

For more information, see [Loading Documents into JSON Tables](#) on page 1647. The default value is incremental bulkload.

6. (Optional) Configure the following **Security** settings:

a) Click **Security** on the **Create New Table** page to open and display security options (if not already displayed). Fields and options for the **Security Policy**, **Audit**, and **Default Data Access Control for Column Families** appear.

b) Enter the name or the first few characters of an existing security policy in the **Search for security policy** field until the needed policy appears below the search box. The selected security policy is associated with the current table being created.

NOTE: The **Search for security policy** field under the **Security** pane appears only if security policies have been previously created. If the **Search for security policy** field does not appear under the **Security** pane, then, using the appropriate privileges, go to the **Security** screen, and set up necessary security policies.

c) Click the checkbox next to the name of the listed security policy you intend to use for this table.

d) Click **Add**. The name of the security policy that you selected appears above the search box. The security policy selected (along with its current data masking setting) is then associated with this table.

7. For the **Enable Auditing** field, either enable (**Yes**) or disable (**No**) auditing to audit table operations. If auditing is enabled at the cluster and volume levels, it causes auditing to start for the table operations.

8. Define **Default Data Access Control for Column Family** settings:

- a) Select either **Basic** or **Advanced**:

NOTE: If you switch from **Basic** to **Advanced**, the basic settings, if any, are carried over to the advanced settings. If you switch from **Advanced** to **Basic**, all the settings are lost because the subexpressions and AND (&) and negation (!) operations that are supported by advanced settings are not supported in the basic settings.

- If you select **Basic** from the **Security** pane of the **Create New Table** page, then select a user type, enter a name in the **Name** field, and check associated permissions for the settings, as needed.

NOTE: You *cannot* specify **User**, **Group**, or **Role** individually if access is granted to all users (**Public**).

Selected permissions become the default table permissions after creating column families under this table and are displayed under the **DEFAULT DATA ACCESS CONTROL FOR COLUMN FAMILIES** pane of the **Create New Table** page.

JSON Table Security Permission Options

Permission	Permission Description
Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.

Permission	Permission Description
Traverse Data	<p>Can pass over fields in JSON documents. For example, suppose that a JSON table contains documents of this general structure:</p> <pre> { "_id" : "ID", "a" : { "b" : "value", "c" : "value" } }</pre> <p>Suppose further that the user sjohnson has read permission on a . b, but not on a. For sjohnson to read a . b, the user needs the traverse permission on a. The user can then pass over field a to a . b. This permission is inherited by fields within the column family.</p>
Set Compression	Can set or change the compression setting for the column family.
Unmasked Data	Leaving the Unmask Data checkbox unchecked hides table column family data from the selected user. Checking the box allows the selected user to see all table data, based on and in coordination with other security and data access settings.

Binary Table Security Permission Options

Permission	Permission Description
Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.

Permission	Permission Description
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Append Data	Can do column appends. Column appends require permission both at the column-family level and at the column level.
Set Version	Can set or change the maximum and minimum number of versions of column values to keep.
Set Compression	Can set or change the compression setting for the column family.

- If you select **Advanced** from the **Security** pane of the **Create New Table** page, then specify public (p) or user (u), group (g), and/or role (r) and indicate, if required, user access options with the following boolean expressions and subexpressions:
 - ! — Negation operator.
 - & — AND operation.
 - | — OR operation.

Use (), parentheses, for subexpressions.

NOTE: You *cannot* specify **User**, **Group**, or **Role** individually if access is granted to all users (**Public**).

NOTE: By default, all table permissions are given to the user creating the table.

Alternatively, click  associated with the type of access to use the selected **Access Control Expression** window to define access for **Public** or **User**, **Group**, and/or **Role**.

b) Opt to:

- Create a copy of permission settings for a listed public, user, group, or role type by clicking , which you can then modify.
- Delete permission settings for a listed public, user, group, or role type by clicking .

9. Optionally, repeat the above [step](#) to add another user type, as needed. Otherwise, proceed to the next step.

10. Do one of the following to specify settings under the **Table Administration Control** pane of the **Create New Table** page:

- Click **Basic** under the **Table Administration Control** pane, select **Public** (to grant access to all users) or **User**, **Group**, or **Role**. Then, enter a name for the current permission set in the **Name** field, and apply table permissions as described in the table below.

Table Administration Control Permission Options for JSON Tables

Permission	Permission Description
Administration	Can view and edit the permissions for the table.
Force Pack	Can pack table regions.
Split Merge	Can take the following actions: <ul style="list-style-type: none"> Split the table into regions or merge regions of the table together. Change the size of the region.
Index	Can create index for this table.
Bulkload	Can load this table with bulk loads if the table was created with bulk load support.
Replication Access	Can set up replication either to or from a table.
Create/Rename Column Family	Can create column families for this table or rename existing column families.
Delete Column Family	Can delete column families associated with the table.

Table Administration Control Permission Options for Binary Tables

Permission	Permission Description
Administration	Can view and edit the permissions for the table.
Force Pack	Can pack table regions.
Split Merge	Can take the following actions: <ul style="list-style-type: none"> Split the table into regions or merge regions of the table together. Change the size of the region.

Permission	Permission Description
Bulkload	Can load this table with bulk loads if the table was created with bulk load support.
Replication Access	Can set up replication either to or from a table.
Create/Rename Column Family	Can create column families for this table or rename existing column families.
Delete Column Family	Can delete column families associated with the table.

- Click **Advanced**, and then apply user permissions.

Specify public (p) or user (u), group (g), and/or role (r) who have or do not have the type of access using the following boolean expressions and subexpressions:

- ! — Negation operator.
- & — AND operation.
- | — OR operation.

Use (), parentheses, for subexpressions.

NOTE: You *cannot* specify user, group, or role individually if access is granted to all users (public).

Alternatively, click  associated with the type of access to use the selected **Access Control Expression** window to define access for public or users, groups, and/or roles.

NOTE: If you switch from **Basic** to **Advanced**, the basic settings, if any, are carried over to the advanced settings. If you switch from **Advanced** to **Basic**, all the settings are lost because the subexpressions and AND (&) and negation (!) operations that are supported by advanced settings are not supported in the basic settings.

- Optionally, click **Add Another** from the **Table Administration Control** pane of the **Create New Table** page, and repeat the above [step](#) to assign security permissions for another user type. Otherwise, proceed to the next step.
- Review and update your selections, as needed.
- Click **Create Table** at the bottom of the **Create New Table** page to create the table.
- Opt to do the following:
 - [Add](#) column families to the table.
 - [View](#) the table information for the newly created table.

Creating a Table Using the CLI or the REST API

About this task

CLI

The basic command to create a binary table is:

```
maprcli table create -path <path>
```

To create a JSON table, include the `-tabletype` parameter and set it to `json`:

```
maprcli table create -path  
<path> -tabletype json
```

The `-tabletype` parameter is set to `binary` by default.

REST

Send a request of type `POST`. For example, to create a:

- Binary table:

```
curl -X POST 'https://  
<hostname>:8443/rest/table/create?  
path=<path>' --user  
<username>:<password>
```

- JSON table:

```
curl -X POST 'https://  
<hostname>:8443/rest/table/create?  
path=<path>&tabletype=json' --user  
<username>:<password>
```

The format of the value of the `-path` parameter depends on whether you are creating a table on a local cluster or a remote cluster:

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customer`

NOTE: You cannot use the following characters in the table name:

```
< > ? % \
```

To use the following characters in the table name, enclose them either in single or double quotes:

```
 ; | ( ) /
```

For example:

```
maprcli table create -path "/^=#;{}&()/" (or)  
maprcli table create -path '/^=#;{}&()/'
```

To use either the ' or the " character in the table name, enclose:

- the ' character within double quotes (")
- the " character within single quote (')

For example:

```
maprcli table create -path "'^=#;{}&()/'" (or)
maprcli table create -path '"^=#;{}&()/'"
```

If you create a table, you can set a number of properties. Refer to the `table create` command..

Creating Tables Using shell Command

About this task

JSON Tables

The HPE Data Fabric Database shell command is used on JSON tables only. To run this command, execute the following:

```
mapr dbshell
```

After starting the shell, run the `create` command.

Binary Tables

The HBase shell command is used on binary tables only. To run this command, execute the following:

```
hbase shell
```

After starting the HBase shell, run the `create` command. Type `help` to see a list of commands and their syntax.

Related tasks

[Editing Tables](#) on page 1617

Explains how to edit binary and JSON tables using either the Control System, the CLI, or the REST API.

[Removing a Table](#) on page 1623

Use either the Control System or the `maprcli table delete` command to drop a HPE Data Fabric Database table.

[Creating Column Families](#) on page 1653

Explains how to create column families using either the Control System, the CLI, or the HBase shell.

Configuring Maximum Row Sizes Using the CLI

The default maximum row size at installation is 32MB. You can configure this maximum by changing the value of the `mfs.db.max.rowsize.kb` parameter with the `maprcli config save` command.

Tables support rows up to 2 GB in size. Rows in excess of 100MB might show decreased performance.

Here is an example of changing the maximum row size:

```
maprcli config save -values {"mfs.db.max.rowsize.kb":<value in KB>}
```

The value of this parameter affects both JSON tables and binary tables.

To view the current setting of this parameter, use the `maprcli config load` command, as in this example:

```
maprcli config load -json | grep mfs.db.max.rowsize.kb
```

Editing Tables

Explains how to edit binary and JSON tables using either the Control System, the CLI, or the REST API.

About this task

You can use the Control System, the CLI, or the REST API to edit the attributes of a HPE Data Fabric Database binary or JSON table. You can also use the HBase shell to edit a binary table. To edit a table, you must have the following permissions:

- readAce and writeAce on the volume
- lookupdir on directories in the path
- adminaccessperm on the table

Editing Tables Using the Control System

Procedure

1. Log into the Control System using your login credentials. The Control System **Overview** page appears.

NOTE: This option is not available on the Kubernetes version of the Control System.

2. Click **Data > Tables** from the top of the page. The **Tables** page appears.
See [Viewing Table Information](#) on page 1630.
3. Select the table needing to be edited (under the **Recently Viewed Tables** pane or in the bottom pane) or enter the path to the needed table in the available field, and then click **Edit Table** to display the **Edit Table** page.
4. Make changes to the following **Properties**, where necessary:

Property	Property Description
Metrics Interval	Select 10 sec , 1 min or 10 min to update the interval of time for logging metrics.
Auto Split	Enable (Yes) or disable (No) auto-splitting of table. If enabled, the table is split automatically into regions as the table grows. If disabled, the table can be split manually into regions. By default, this is enabled.
Bulkload	Enable (Yes) or disable (No) full bulk load of the table.

5. Define **Default Data Access Control for Column Family** settings:

- a) Select either **Basic** or **Advanced**:

NOTE: If you switch from **Basic** to **Advanced**, the basic settings, if any, are carried over to the advanced settings. If you switch from **Advanced** to **Basic**, all the settings are lost because the subexpressions and AND (&) and negation (!) operations that are supported by advanced settings are not supported in the basic settings.

- If you select **Basic** from the **Security** pane of the **Create New Table** page, then select a user type, enter a name in the **Name** field, and check associated permissions for the settings, as needed.

NOTE: You *cannot* specify **User**, **Group**, or **Role** individually if access is granted to all users (**Public**).

Selected permissions become the default table permissions after creating column families under this table and are displayed under the **DEFAULT DATA ACCESS CONTROL FOR COLUMN FAMILIES** pane of the **Create New Table** page.

JSON Table Security Permission Options

Permission	Permission Description
Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Traverse Data	<p>Can pass over fields in JSON documents. For example, suppose that a JSON table contains documents of this general structure:</p> <pre> { "_id" : "ID"/ "a" : { "b" : "value"/ "c" : "value" } } </pre> <p>Suppose further that the user sjohnson has read permission on a . b, but not on a. For sjohnson to read a . b, the user needs the traverse permission on a. The user can then pass over field a to a . b. This permission is inherited by fields within the column family.</p>
Set Compression	Can set or change the compression setting for the column family.

Permission	Permission Description
Unmasked Data	Leaving the Unmask Data checkbox unchecked hides table column family data from the selected user. Checking the box allows the selected user to see all table data, based on and in coordination with other security and data access settings.

Binary Table Security Permission Options

Permission	Permission Description
Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Append Data	Can do column appends. Column appends require permission both at the column-family level and at the column level.
Set Version	Can set or change the maximum and minimum number of versions of column values to keep.
Set Compression	Can set or change the compression setting for the column family.

- If you select **Advanced** from the **Security** pane of the **Create New Table** page, then specify public (p) or user (u), group (g), and/or role (r) and indicate, if required, user access options with the following boolean expressions and subexpressions:
 - **!** — Negation operator.
 - **&** — AND operation.
 - **|** — OR operation.

Use (), parentheses, for subexpressions.

NOTE: You *cannot* specify **User**, **Group**, or **Role** individually if access is granted to all users (**Public**).

NOTE: By default, all table permissions are given to the user creating the table.

Alternatively, click associated with the type of access to use the selected **Access Control Expression** window to define access for **Public** or **User**, **Group**, and/or **Role**.

b) Opt to:

- Create a copy of permission settings for a listed public, user, group, or role type by clicking , which you can then modify.
- Delete permission settings for a listed public, user, group, or role type by clicking .

6. Make changes as needed to **Table Administration Control settings:**

- a) Modify the list of users, groups, and/or roles that have and/or do not have the following types of administration permissions on the table, as applicable:

JSON Table

Field	Field Description
Admin	Can view and edit the permissions for the table.
Index	Can create an index for the table.
Force Pack	Can pack table regions.
Split Merge	Can take the following actions: <ul style="list-style-type: none"> • Split the table into regions or merge regions of the table together. • Change the size of the region.
Bulkload	Can load this table with bulk loads if the table was created with bulk load support.
Replication Access	Can set up replication either to or from a table.
Create/Rename Column Family	Can create column families for this table or rename existing column families.
Delete Column Family	Can delete column families associated with the table.

Binary Table

Field	Field Description
Admin	Can view and edit the permissions for the table.
Force Pack	Can pack table regions.
Split Merge	Can take the following actions: <ul style="list-style-type: none"> Split the table into regions or merge regions of the table together. Change the size of the region.
Bulkload	Can load this table with bulk loads if the table was created with bulk load support.
Replication Access	Can set up replication either to or from a table.
Create/Rename Column Family	Can create column families for this table or rename existing column families.
Delete Column Family	Can delete column families associated with the table.

b) Opt to:

- Grant access to a new user, group, or role by clicking **Add Another**, selecting the **Type** entity, entering the **Name** entity, and selecting the permissions to grant the entity.
- Create a copy of permission settings for a listed public, user, group, or role type by clicking . You can then modify the copied settings, if necessary.
- Delete permission settings for a listed public, user, group, or role type by clicking .

7. Click **Save Changes** for the changes to take effect.

Editing Tables Using the CLI or the REST API**About this task****CLI**

The following is the command to edit a table:

```
maprcli table edit -path <path>
```

REST

Send a request of type POST. For example:

```
curl -k -X
POST 'https://<hostname>:8443/rest/
```

```
table/edit?path=<path>' --user
<username>:<pwd>
```

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customer`

NOTE: You cannot use the following characters in the table name:

```
< > ? % \
```

To use the following characters in the table name, enclose them either in single or double quotes:

```
 ; | ( ) /
```

For example:

```
maprcli table create -path "/^=#;{}&()/" (or)
maprcli table create -path '/^=#;{}&()/'
```

To use either the `'` or the `"` character in the table name, enclose:

- the `'` character within double quotes (`"`)
- the `"` character within single quote (`'`)

For example:

```
maprcli table create -path "/"'^=#;{}&()/" (or)
maprcli table create -path '/"'^=#;{}&()/'
```

When you edit a table, you can change a number of properties including:

- Enable or disable auditing, autosplitting, and bulkloading
- Set permissions on table
- Set permissions for default column families

For full reference for this command, see the `table edit` command.

Editing Binary Tables Using HBase Shell

About this task

After starting the HBase shell, run the `alter` command. Type `help` to see a list of commands and their syntax.

Related tasks

[Creating a New Table](#) on page 1608

Explains how to create both binary tables and JSON tables using either the Control System, the CLI, or the REST API.

[Removing a Table](#) on page 1623

Use either the Control System or the `maprccli table delete` command to drop a HPE Data Fabric Database table.

Removing a Table

Use either the Control System or the `maprccli table delete` command to drop a HPE Data Fabric Database table.

Removing a Table Using the Control System

About this task

To remove a table:

Procedure

1. Go to the table information page.
See [Viewing Table Information](#) on page 1630.
2. Click **Remove Table**.
The **Remove Table** confirmation window displays.
3. Click **Remove Table** to remove the table.
After the table is removed, data in the table cannot be recovered.

Removing a Table Using the CLI or REST API

About this task

Run the command `maprccli table delete -path <path> .`

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customer`

NOTE: You cannot use the following characters in the table name:

`< > ? % \`

To use the following characters in the table name, enclose them either in single or double quotes:

`; | ( ) /`

For example:

```
maprccli table create -path "/^=#;{}&()/" (or)
maprccli table create -path '/^=#;{}&()/'
```

To use either the `'` or the `"` character in the table name, enclose:

- the `'` character within double quotes (`"`)
- the `"` character within single quote (`'`)

For example:

```
maprcli table create -path "/"^=#;{}&()/" (or)
maprcli table create -path '/'^=#;{}&()/'
```

For more information, see the `table delete` command.

Defining ACEs Using the Access Control Expression Builder
Describes how to build ACEs using the Expression Builder.

About this task

To define access control expressions using the **Access Control Expression** builder in the Control System:

Procedure

- 1. Choose **All** or **Any** (from the drop-down menu) of the settings to match for access.
Here:

All	AND (&) operation	Indicates that all of the conditions must be met for public or user, group, and role to access the volume.
Any	OR () operation	Indicates that any one of the conditions must be met for public or user, group, and role to access the volume.

- 2. Click:

+	To add an expression.
()	To add a subexpression.
x	To remove an expression or subexpression.

- 3. Select **Public** or **User**, **Group**, or **Role** from the drop-down menu and:
 - a) Choose **Is** to grant or **Is not** to block access to the user, group, or role.
 - b) Enter the name of the user, group, or role.
- 4. Click **Save Changes** to create an ACE.

Setting Whole Volume ACEs Using the CLI

Setting Table ACEs Using the CLI

About this task
See [Enabling Table and Stream Authorizations with ACEs](#) on page 1625.

Setting Stream ACEs Using the CLI

About this task

See [Enabling Table and Stream Authorizations with ACEs](#) on page 1625.

Enabling Table and Stream Authorizations with ACEs

About this task

Permissions for Data Fabric tables, column families, and columns are defined by ACEs. Set permissions for tables after you create or edit tables. Set default permissions for column families when you create or edit tables, and you can override these defaults when you create column families.

For the syntax to use when creating Access Control Expressions, see [ACE Syntax](#) on page 2126.

If a user, group, or role requests to read data from, write data to, or append data to a column, HPE Data Fabric Database checks whether that user, group, or role has read or write permission for the column family AND read or write permission for the column. By default, columns allow read and write access to all users; in such cases, only the read or write permission for the column family matters.

However, suppose that a table contains columns `col1` and `col2` in column family `cf1`, and these columns grant read and write permission only to the table creator. A different user tries to write data to these columns. HPE Data Fabric Database checks whether this user has write permission on `cf1` AND `col1` AND `col2`. If the user does not have all three permissions, HPE Data Fabric Database returns an error that says access for the write is denied.

If this user were to try to read from the same two columns, HPE Data Fabric Database would simply not return the data. If the user tried to read from those two columns and additional columns on which he had read permissions, the results would contain the data for those additional columns but exclude the data for `col1` and `col2`.

NOTE: Table Permissions for Older Releases: Because Data Fabric tables are stored at the file-system level, you can also set permissions for HPE Data Fabric Database tables directly in the file system, if your version of Data Fabric does not support ACEs. Support for ACEs was introduced in version 3.1.

To set permissions directly in the filesystem, see [Performing File System Operations on HPE Data Fabric Database Tables](#) on page 1652.

Setting Table ACEs Using the CLI

About this task

You can set ACEs with the following commands:

- [table create](#) on page 2753 — Creates a new Data Fabric table.
- [table edit](#) on page 2808 — Edits a Data Fabric table.
- [table cf create](#) on page 2778 — Creates a column family for a Data Fabric table.
- [table cf edit](#) on page 2785 — Edits a column-family definition.
- [table cf colperm set](#) on page 2761 — Set Access Control Expressions (ACEs) for a specified column.

Setting Stream ACEs Using the CLI

About this task

You can set ACEs with the following commands:

- [stream create](#) on page 2708 — Creates a new Data Fabric stream.
- [stream edit](#) on page 2715 — Edits a Data Fabric stream.

Defining ACEs by using maprcli commands

You can set ACEs with the following commands:

- [table create](#) : Creates a new Data Fabric table.
- [table edit](#) : Edits a Data Fabric table.
- [table cf create](#) : Creates a column family for a Data Fabric table.
- [table cf edit](#) : Edits a column-family definition.
- [table cf colperm set](#) : Set Access Control Expressions (ACEs) for a specified column.

Defining ACEs with the MCS by using the Expression Builder

Procedure

1. To define an ACE for an existing table, click **Edit Table Permissions** from the table's pane in the MCS to display the **Permissions** pane.

Edit Table Permissions

Permissions

Force purge ▶ ?

Change Autosplit ▶ ?

Column Family Default Permissions

Set min/max versions ▶ ?

Set compression ▶ ?

Pin CF in memory ▶ ?

Read Data ▶ ?

Write Data ▶ ?

- Click the arrow at the right side of any field to display the Expression Builder for that field.

- Use the + button to add a condition to the expression. Note that you cannot mix AND and OR without using subexpressions.

You can also type expressions directly into the field. The MCS validates expressions when focus leaves the field. The field is colored yellow for a warning and red for an error. Hover the cursor on the field to display the error or warning message.

Setting Whole Volume ACEs

Describes how to set ACE expressions when creating or modifying volumes.

You can set [ACEs](#) at the time of volume creation using the [volume create](#) on page 2929 command and modify them at a later time using the [volume modify](#) on page 3018 command. When you run the command to set or modify [ACEs](#), the command does the following:

- Overwrites existing values with new values, if specified, for access types that were previously set.
- Sets values for access types that have not yet been set, if specified.
- Does not modify access types that were not specified with the command, whether they were previously set or are unset.

When you set whole volume [ACEs](#), permissions on files and tables under that volume remain unchanged. Also, new files and tables in the volume do not inherit the whole volume [ACEs](#) of that volume. Instead, whole volume [ACEs](#), if set, are used to determine volume level access to tables and files within the volume. To gain access to volume data, the user must have access at both the volume and file/table levels.

Whole Volume **ACE** Example

For example, suppose the following sequence of whole volume **ACE** settings for users u3 and u4 is as follows.

NOTE: In the following illustration, default **ACE** values are shown in red.

As shown in the illustration above, in:

Step 1:

User u3 is granted permissions to read.

User u3: User u3 has permissions to read files and tables at the volume level and by default, user u3 has write permission (shown in red) at the volume level. However, for:

- Files in the volume, file **ACE** or POSIX mode bits are used to determine read and write access for user u3.
- Tables in the volume, table **ACEs** are used to determine read and write access for user u3.

User u4: User u4 cannot read files and tables within the volume because the **ACE** for the volume does not explicitly grant access to user u4. Although user u4 has write permission by default, user u4 cannot write to files/tables in the volume because user u4 does not have read permission.

Step 2:

User u3 is granted permissions to write.

User u3: User u3's read access remains unchanged and although user u3 has permissions to write to files and tables, for:

- Files in the volume, file **ACE** or POSIX mode bits are used to determine write access for user u3.
- Tables in the volume, table **ACEs** are used to determine write access for user u3.

User u4: User u4 cannot write to files/tables in the volume.

Step 3

User u4 is granted read access.

User u3: User u3's read and write access remains unchanged.

User u4: User u4 has permissions to read files and tables at the volume-level; however, for:

- Files in the volume, file [ACE](#) or POSIX mode bits are used to determine read access for user u4.
- Tables in the volume, table [ACEs](#) are used to determine read access for user u4.

Viewing the List of Tables

Describes how to view the list of tables using either the Control System or the CLI.

Viewing the Tables in a Volume Using the Control System

Procedure

- Log in to the Control System and click **Data > Tables** to view all the volumes to which you have access.

NOTE: This option is not applicable on the Kubernetes version of the Control System.

For each volume, the pane displays the following:

Column Name	Column Description
Name	The name of the volume.
Type	The type. Value can be: <ul style="list-style-type: none"> — Volume — Directory — Table
Owner	The name of the owner.
Last Modified	The last modification date and timestamp.

- Click on the name of the volume (to browse to the path to the table) or enter the name of the volume in the text field.

The tables in the selected volume display. If necessary, click the name of the directory to browse further or to return to **All** volumes view.

Viewing a Table by Table Path Using the Control System

Procedure

- Log in to the Control System and click **Data > Tables**.

NOTE: This option is not applicable on the Kubernetes version of the Control System.

- Enter the path to the table and click **GO**.

The tables information page for the specified table displays.

Listing the Tables in a Directory From the Command-line*Method for Binary Tables Only (HBase Shell)***About this task**

After starting the HBase shell, run the `list` command. Include the directory path in the command if you want to list tables that are not in your home directory. Type `help` to see a list of commands and their syntax.

*Method for JSON Tables Only (mapr dbshell)***About this task**

After starting the shell, run the `list` command. Include the directory path in the command if you want to list tables that are not in your home directory.

Retrieving a Table by Table Path Using the CLI or the REST API**About this task**

To retrieve table details for a table by specifying the table path from the CLI, run the following command:

```
maprccli table info -path <table-path>
```

For information on this command, see the `table info` command.

Viewing Table Information

Explains how to view table information using either the Control System, the CLI or the REST API.

About this task

You can view table information including table properties, column families, regions, replicas, upstream source, indexes, and metrics. Use either the `maprccli` command, REST API, or the Control System to display all of the information that HPE Data Fabric Database stores about a particular table.

Viewing Table Information Using the Control System**Procedure**

1. Search and retrieve the table either by volume or by table path.

For information on retrieving, see:

- [Viewing the Tables in a Volume Using the Control System](#) on page 1629
- [Viewing a Table by Table Path Using the Control System](#) on page 1629

2. Click the name of the table to see the table details.

The page displays the following tabs:

- [Summary](#)
- [Column Families](#)
- [Regions](#)
- [Replication](#)
- [Change Data Capture](#)
- [Indexes](#)

- **Metrics**

On this page, you can:

- [Edit](#) the table
- [Remove](#) table

Viewing Table Information Using the CLI or REST API

About this task

CLI

The basic command to retrieve table information is the following:

```
maprccli table info -path
<tablePath> -json
```

REST

Send a request of type GET to retrieve table details. For example:

```
curl -k -X
GET 'https://<hostname>:8443/rest/
table/info?path=<tablePath>' --user
<username>:<pwd>
```

For more information, see the `table info` command.

Viewing Table Settings

Describes how to view table settings using the Control System, the CLI or the Rest API.
Viewing Table Settings Using the Control System

Procedure

- Log in to the Control System and go to the **Summary** tab in the [table information page](#) to view the following settings.

 **NOTE:** Some properties are only applicable to binary tables.

Throughput - By Op Type

This pane displays a graph for the operations on the table in the last hour. For more information, see *Monitoring Tables*.

Region Data Distribution by Node

This pane shows the distribution of the table or secondary index regions across the nodes in the cluster. For more information, see *Monitoring Tables*.

Properties

This pane shows the current value for the following table properties:

Table Path	The path to the table on the file system.
Table Type	The type of table. Value can be one of the following: <ul style="list-style-type: none">• JSON• Binary
Total Rows	The total number of rows in the table.

Region Size	The average size of the regions into which HPE Data Fabric Database tries to split the table as the table grows. The default is 4096 MB.
Total Logical Size	The estimated size (in bytes) of uncompressed data stored in table (excluding replication).
Total Physical Size	The estimated size (in bytes) of actual data stored in table (excluding replication). This includes internal metadata and reflects compressed data size when compression is enabled.
Auditing	The setting to enable or disable auditing of operations on the table.
Auto Split	The setting to automatically split the table into regions as the table grows.
Bulkload Type	The setting to allow a full bulk load of the table.
Metrics Interval	The table metrics collection interval, in seconds.

Security

This pane shows the following security settings on the table:

Security Policy	<p>The security policies associated with this table including:</p> <ul style="list-style-type: none">• Name of the security policy• Status of the security policy. Lists the path of the table location, name of table column families, and name of associated fields, if any. Click a listed security policy or + (plus sign) to add an additional security policy, or drill down through the listing under Name column, where the Add Field is displayed and add another data field to the table. Remove a security policy by clicking the security policy name to be deleted and then click - (minus sign) from the subsequent screen. <div>NOTE: No warning confirmation screen is displayed whenever you opt to delete a security policy from the Security pane of the table information page.</div> <ul style="list-style-type: none">• Access control expression in the security policy
Audit	Whether or not auditing is enabled for table operations.

Table Admin Control

This pane shows the entities (users, groups, and/or roles) that have and/or do not have one or more of the following types of permissions to administer the table:

Admin (Access Control)	Can view and edit the permissions for the table.
Force Pack	Can pack table regions.

Split Merge	Can take the following actions: <ul style="list-style-type: none"> Split the table into regions or merge regions of the table together. Change the size of the region.
Index	Can create index for this table. This permission is for JSON tables only.
Bulkload	Can load this table with bulk loads if the table was created with bulk load support.
Replication Access	Can set up replication either to or from a table.
Create/Rename Column Family	Can create column families for this table or rename existing column families.
Delete Column Family	Can delete column families associated with the table.

Viewing Table Settings Using the CLI and REST API

About this task

CLI

The basic command to retrieve table information is the following:

```
/opt/mapr/bin/maprccli table
info -path <tablePath> -json
```

REST

Send a request of type GET to retrieve table details. For example:

```
curl -X
GET 'https://<hostname>:8443/rest/
table/info?path=<tablePath>' --user
<username>:<pwd>
```

For more information on the settings, see the `table info` command.

Listing Column Families

Explains how to view the column families for a table using either the Control System or the CLI.

Viewing Table Column Families Using the Control System

About this task

To view the column families for a table:

Procedure

1. Go to the table information page.
See [Viewing Table Information](#) on page 1630.

2. Click the **Column Families** tab.

The page displays the default permissions for the column families in the **Default Column Family Authorization** pane, and for each column family, the **All** pane displays:

Column Name	Column Description
Column Family Name	The name of the column family.
JSON Path	The JSON path for the column in the JSON file in dotted notation.
Compression	The compression scheme used for the column family.
Time-to-Live	The amount of time to keep the data in the column family.
In Memory	Whether or not this column value resides in memory.

Selecting the checkbox associated with the column family makes the **Remove Column Family** button available. You can:

- [Add](#) a column family to the table
- [Remove](#) a column family associated with the table

Viewing Table Column Families Using the CLI or REST API

About this task

The command to list the column families that are in a table is:

```
maprcli table cf list -path <path> -cfname <name_of_column_family>
```

The format of the value of the `-path` parameter depends on whether you are viewing a table on a local cluster or a remote cluster:

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customer`

NOTE: You cannot use the following characters in the table name:

```
< > ? % \
```

To use the following characters in the table name, enclose them either in single or double quotes:

```
; | ( ) /
```

For example:

```
maprcli table create -path "/^=#;{}&()/" (or)
maprcli table create -path '/^=#;{}&()/'
```

To use either the ' or the " character in the table name, enclose:

- the ' character within double quotes (")
- the " character within single quote (')

For example:

```
maprcli table create -path "'^=#;{}&()/'" (or)
maprcli table create -path '"^=#;{}&()/'
```

To run this command, your user ID must have the following permissions:

- readAce on the volume
- lookupdir on directories in the paths
- adminaccessperm on the table

For complete reference, see the `table cf list` command.

Viewing Table Regions

Use either the Control System or the CLI to list the regions in which a table's data is located.

About this task

HPE Data Fabric Database tables are split into regions on an ongoing basis. Administrators and developers do not need to manage these regions or restructure data on disk when data is added and deleted. These operations happen automatically. You can view region information for tables to get a sense of the size and location of table data on the Data Fabric cluster.

Displaying the Regions Using the Control System

About this task

To display the regions of a table:

Procedure

1. Go to the table information page.
See [Viewing Table Information](#) on page 1630.
2. Do one of the following:
 - Click **Regions** to view the list of regions for the table.
 - Click the name of the index in the **Indexes** tab to view the regions for the index.

For each region, the **Regions** pane displays the following:

Column Name	Column Description
Start Key	Value of the start key for this region. For the first region in a table, this value is exclusive. For all other regions, it is inclusive.
End Key	Value of the end key for this region. This value is always exclusive.
Physical Size	The physical size of the region with data compression (excluding replication).

Column Name	Column Description
Logical Size	The logical size of the region without data compression (excluding replication).
No of Rows	Number of rows in the region.
Primary Node	The host name and port of the primary node for this region.
Secondary Node	The host names and ports of the secondary nodes where this region is replicated.
Last HB	The time since last heartbeat from the region's primary node.
Region Identifier	The region's FID.

Displaying Region Information Using the CLI or the REST API

About this task

The basic command to retrieve the list of regions that make up the table is:

```
maprcli table region list -path <path>
```

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named test under a volume with a mount point at /volume1, specify the following path: /volume1/test
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named customer under volume1 in the sanfrancisco cluster, specify the following path: /mapr/sanfrancisco/volume1/customer

NOTE: You cannot use the following characters in the table name:

```
< > ? % \
```

To use the following characters in the table name, enclose them either in single or double quotes:

```
; | ( ) /
```

For example:

```
maprcli table create -path "/^=#;{}&()/" (or)
maprcli table create -path '/^=#;{}&()/'
```

To use either the ' or the " character in the table name, enclose:

- the ' character within double quotes (")
- the " character within single quote (')

For example:

```
maprcli table create -path "'^=#;{}&()/" (or)
maprcli table create -path '"^=#;{}&()/'
```

The json parameter displays the output as a JSON document.

To run this command, your user ID must have the following permissions:

- readAce on the volume
- lookupdir on directories in the path

See [table region list](#) on page 2833.

Displaying the List of Table Replicas

Describes how to view information on the table replicas using the Control System or the CLI.

Displaying the List of Table Replicas Using the Control System

About this task

To view table replicas:

Procedure

1. Log in to the Control System and go to the [table information page](#).
2. Click **Replication**.

The page displays all the replicas and for each replica, the pane displays the following statistics:

Column Name	Column Description
Paused	Whether replication is paused.
Destination Cluster	The cluster on which the replica resides.
Destination Path	The path to the destination.
Status	<p>The status of the replica. Replicas can be in one of the following states:</p> <ul style="list-style-type: none"> • In-Synch — indicates replica is in synch with the source table and there are no more bytes to be sent from the source. • Pending — indicates replica is waiting for some bytes to be sent from the source. You can hover over the status to determine the number of bytes, puts, and buckets pending. • Broken — indicates there was an error during replication. If necessary, remove and re-create the replica.
Earliest	The epoch time in milliseconds of the oldest operation that is yet to be replicated to the replica.
Latest	The epoch time in milliseconds of the newest operation that is yet to be replicated to the replica.
Errors	Error () information, if any.
Compression Type	The type of on-wire compression.
Synchronous	Whether replication is synchronous or asynchronous.
Throttled	Whether replication is throttled.
Encrypted	Whether replication is encrypted.

*Retrieving List of Table Replicas Using the CLI or the REST API***About this task**

To view table replicas and associated replica statistics for a table, run the following command:

```
maprcli table replica list -path <table-path>
```

For more information, see [table replica list](#) on page 2853

Viewing the List of Change Logs

Explains how to view the list of change logs using the Control System or the CLI.

Viewing the List of Change Logs Using the Control System

Procedure

- Log in to the Control System and go to the **Change Data Capture** tab in the [table information page](#).
For each change log, the page displays the following:

Column Name	Column Description
Edit Change Log	Shortcut to the Edit Change Log window for editing a change log.
Paused	Specifies whether the change propagation is paused for the associated change log.
Destination Cluster	Specifies the destination cluster on which the stream exists.
Destination Stream Topic Name	Specifies the name of the stream associated with the change log.
Up to Date	Specifies whether (Yes) or not (No) the change log is up to date. If value is No , hover the cursor over the value to see the number of pending bytes, puts, and buckets.
Errors	Indicates whether there were any errors during change propagation.
Compression Type	The type of compression for data transfer between file system and gateway for the associated change data log instance
Synchronous	Specifies whether client writes to the table should be acknowledged before the CDC gateway receives the data.
Throttle	Specifies whether data transfer to the stream for the associated change data log is throttled.
Encrypted	Specifies whether the data transfer between file system and gateway for the associated change data log is encrypted.
Field Path	Specifies whether only specific field paths are being published to the stream topic.

*Retrieving the List of Change Logs Using the CLI or REST API***About this task**

The basic command to retrieve the list of change data logs is:

```
maprcli table changelog list
```

For complete reference, see [table changelog list](#) on page 2802.

Listing Secondary Indexes

Describes how to list information about the secondary indexes created on HPE Data Fabric Database JSON tables.

About this task

You can view secondary indexes using the Control System or the `maprc li table index` commands. You need the following permissions.

- `readAce` on the volume
- `lookupdir` on directories in the table path

NOTE: The `mapr` user is not treated as a superuser. HPE Data Fabric Database does not allow the `mapr` user to perform this operation unless that user is given the relevant permission or permissions with access-control expressions.

Listing Indexes in the Control System

Procedure

- Log in to the Control System and go to the **Indexes** tab in the [table information page](#).

The list of indexes displays in the **All indexes** pane and for each index, the page displays the following:

Column Name	Column Description
Index Name	The name of the index
Fields Indexed	The number of fields on the JSON table that are indexed and used for ordering
Fields Covered	The number of fields on the JSON table that are indexed, but not used for ordering
State	The replication state of the index
Up to Date	Whether the index is up to date
Hashed	Whether the index is hashed
Size	The size of the index

What to do next

To view more details on individual indexes, see [Viewing Secondary Index Details](#) on page 1735.

Listing Indexes Using the CLI

About this task

The following is basic command for listing secondary indexes.

```
maprc li table index list
    -path <path>
    -refreshnow < true | false >
```

See [table index list](#) on page 2821 for more information.

Viewing Table Metrics in the Control System

Explains how to view primary and secondary table index metrics using the Control System.

A subset of the following primary table and secondary index metrics are available as charts and lists in the Control System. For information on how to:

- View these metrics in the Control System, see [Monitoring Tables](#) on page 1940.
- Customize the charts you see on the page, see [Creating a Custom Board for the Charts](#) on page 1927.
- Customize columns you see on the page, see [Adding and Removing Columns from the List View](#) on page 1928.

Chart/Column Name	Metric	Description
Table Bytes Read Per Node	Throughput - bytes read	The number of bytes read from the primary table per node for all RPC types.
Table and Index Bytes Read		The number of bytes read across a primary table and its secondary indexes for all RPC types.
Table Bytes Written Per Node	Throughput - bytes written	The number of bytes written to the primary table per node for all RPC types.
Table and Index Bytes Written		The number of bytes written across a primary table and its secondary indexes for all RPC types.
Table Rows Read Per Node	Throughput - rowCount read	The number of rows read from the primary table per node for all RPC types.
Table and Index Rows Read		The number of rows read across a primary table and its secondary indexes for all RPC types. This is displayed in the default list view for a node.
Table Rows Written Per Node	Throughput - rowCount written	The number of rows written to the primary table per node for all RPC types.
Table and Index Rows Written		The number of rows written across a primary table and its secondary indexes for all RPC types.
All Tables Written Rows Throughput		Number of rows written by RPC operation type.
Table Rows Responded Per Node	Throughput - rowCount returned	The number of rows returned from the primary table per node for all RPC types.
Table and Index Rows Responded		The number of rows returned across a primary table and its secondary indexes for all RPC types. This is displayed in the default list view for a node.
Scan Throughput		Compares the scan throughput for rows read versus rows returned. This is displayed in the default chart view for a node and for a table.

Chart/Column Name	Metric	Description
All Tables Throughput	Throughput - rpcCount/second	Number of RPC operations by type for all tables in the cluster. This is displayed in the default chart view for all the tables.
Throughput by Rpc Type		The combined RPC load for the primary table and its indexes.
All Tables RPC Byte Throughput		The number of bytes processed by RPC operation type.
All Tables Read Rows Throughput		Number of rows processed by RPC operation type.
All Tables Returned Rows Throughput		Number of rows returned by RPC operation type.
Put and Append Operation Throughput		Number of put and append RPC operations for the table, including its indexes.
Table Check and Put Ops Per Node		The number of check and put operations completed for a primary table and for a node.
Table Update and Get Ops Per Node		The number of update and get operations completed for a primary table and for a node.
Table Get and Index Scans		The number of get and index scans completed for a primary table and for a node.
Table Write and Index Maintenance Activity		The number of table writes (puts, appends, increments, check and puts, update and gets) that require puts to the index.
Table Get Ops Per Node		The number of get operations completed for a primary table and for a node. This is displayed in the default list view for a node and for a table.
Table Get Throughput Per Node		The number of get operations completed per second for a table, excluding its secondary indexes, per node. This is displayed in the default chart view for a node and for a table.
Table Increment Ops Per Node		The number of increment operations completed for a primary table and for a node.
Table Put Ops Per Node		The number of put operations completed for a primary table and for a node. This is displayed in the default list view for a node and for a table.
Table Scan Ops Per Node		The number of scan operations completed for a primary table and for a node.
Table Append Ops Per Node		The number of append operations completed for a primary table and for a node.
Table Write Throughput Per Node		The number of put and append operations per second completed for

Chart/Column Name	Metric	Description
Table and Index Scan Latency	Latency	The 99th percentile latency of all scan operations across the primary table and its secondary indexes. A bad ratio between rows read and responded with high scan latency may indicate a poorly configured index.
Table and Index Scan Latency Per node		The 99th percentile latency of scan operations completed across the primary table and secondary index per node. Large scans may hit the disks and result in poor performance, or a degrading disk may spike the latency.
Table Append Latency Per Node		The 99th percentile latency of append operations on the primary table per node.
Table Increment Latency Per Node		The 99th percentile latency of increment operations on the primary table per node.
Table Put Latency Per Node		The 99th percentile latency of put operations on the primary table per node. This is displayed in the default list view for a node and for a table.
Table Get Latency Per Node		The 99th percentile latency of get operations on the primary table per node. This is displayed in the default list view for a node and for a table.
Table Scan Latency Per Node		The 99th percentile latency of scan operations on the primary table per node.
Table Get Latency Percentiles*		The get operation latency by percentile for the primary table and its secondary indexes.
Primary Table Put & Append Latency Percentiles*		The pure write operation latency by percentile for the primary table and its secondary indexes.
Table Write Throughput Latency Percentiles		The 99th percentile latency of put operations on the primary table per node. This is displayed in the default chart view for a node and for a table.
Table Get Throughput Latency Percentiles		The 99th percentile latency of get operations on the primary table per node. This is displayed in the default chart view for a node and for a table.
Table Check and Put Latency Per Node		The 99th percentile latency of check and put operations on the primary table per node.
Table Update and Get Latency Per Node		The 99th percentile latency of update and get operations on the primary table per node.
Index Put Latency		The 99th percentile latency of put operations per secondary index of the

Chart/Column Name	Metric	Description
All Tables Replication Sent Bytes	Replication - rows/bytes sent	The number of bytes of replication data sent.
All Tables Replication Pending Bytes	Replication - rows/bytes pending	The number of bytes of replication data not yet sent.
All Tables Replication Activity	Replication - rows/bytes sent/pending	Number of bytes of replication data sent vs not yet sent. This is displayed in the default chart view for all the tables.
Index Throughput by RPC Type	Index - Throughput	The combined RPC load for the primary table and its secondary indexes.
Index Put Ops		The number of put operations completed per secondary index of the primary table.
Index Put Ops Per Node		The number of put operations completed per secondary index of the primary table per node.
Index Scan Ops		The number of scan operations completed per secondary index of the primary table.
Index Scan Ops Per Node		The number of scan operations completed per secondary index of the primary table per node.
Index Bytes Read	Index - rows/bytes read	The number of bytes read per secondary index of the primary table for all RPC types.
Index Bytes Read Per Node		The number of bytes read per secondary index of the primary table per node for all RPC types.
Index Bytes Written Per Node		The number of bytes written per secondary index of the primary table per node for all RPC types.
Index Rows Read		The number of rows read per secondary index of the primary table for all RPC types.
Index Rows Read Per Node		The number of rows read per secondary index of the primary table per node for all RPC types.
Index Rows Responded	Index - rows/bytes returned	The number of rows returned per secondary index of the primary table for all RPC types.
Index Rows Responded Per Node		The number of rows returned per secondary index of the primary table per node for all RPC types.
Index Scan Read vs Returned Rows	Index - rows/bytes read	The number of secondary index rows that were read versus returned.

Chart/Column Name	Metric	Description
Index Bytes Written	Index - rows/bytes write	The number of bytes written per secondary index of the primary table for all RPC types.
Index Rows Written		The number of rows written per secondary index of the primary table for all RPC types.
Index Rows Written Per Node		The number of rows written per secondary index of the primary table per node for all RPC types.
All Tables Index Sent Bytes	Index - rows/bytes sent	The number of bytes sent for secondary index updates.
All Tables Index Pending Bytes	Index - rows/bytes pending	The number of bytes of secondary index data remaining to be sent.
All Index Maintenance Activity		Number of bytes of index data sent vs not yet sent. This is displayed in the default chart view for all the tables.
All Tables CDC Sent Bytes	CDC - rows/bytes sent	The number of bytes of CDC data sent.
All Tables CDC Pending Bytes	CDC - rows/bytes pending	The number of bytes of CDC data per node not yet sent.
All Tables CDC Propagation Activity		The number of bytes of CDC data sent vs not yet sent. This is displayed in the default chart view for all the tables.
All Streams Producer Ops	Streams Throughput, RPCs	The number of Streams producer RPCs.
All Streams Consumer Ops		The number of Streams consumer RPCs.
All Streams Producer Messages	Streams Throughput, messages	The number of Streams messages produced.
All Streams Consumer Messages		The number of Streams messages read by consumers.
Table Value Cache All Lookups	Value Cache Lookups	All operations for a primary table and for a node that performed a cache lookup.
Table Value Cache Lookups		The number of get operations for a primary table and for a node that performed a cache lookup.
Table Value Cache Lookups Per Index		The number of get operations for a primary table and for a node that performed a cache lookup.

Chart/Column Name	Metric	Description
Table and Index Value Cache All Lookups	Value Cache Hits	All operations across the primary table and its secondary indexes that performed a cache lookup.
Table and Index Value Cache Lookups Per Index		The number of get operations across the primary table and its secondary indexes that performed a cache lookup per secondary index.
Table and Index Value Cache Lookups		The number of get operations across the primary table and its secondary indexes that performed a cache lookup.
Table Value Cache All Hits		All operations for a primary table and for a node that resulted in a cache hit.
Table Value Cache Hits		The number of get operations for a primary table and for a node that resulted in a cache hit.
Table Value Cache Hits Per Index		The number of get operations for a primary table and for a node that resulted in a cache hit.
Table and Index Value Cache All Hits		All operations across the primary table and its secondary indexes that resulted in a cache hit.
Table and Index Value Cache Hits		The number of get operations across the primary table and its secondary indexes that resulted in a cache hit.
Table and Index Value Cache Hits Per Index		The number of get operations across the primary table and its secondary indexes that resulted in a cache hit per secondary index.
Value Cache Utilization	Value Cache	Compares the relative distribution of get operations that either hit the cache or require a lookup. This is displayed in the default chart view for a node and for a table.
All Tables Flushes	Bucket Flushes	The number of table flushes that were manually and automatically triggered. Table flushes reorganize data from bucket files (unsorted data) to spill files (sorted data) when the bucket size exceeds a threshold. This is displayed in the default chart view for all the tables.
All Tables Flushes		The number of total table flushes that were manually versus automatically triggered.
All Tables Force Flushes	Bucket Force Flushes	The number of table flushes that were not automatically triggered.

Chart/Column Name	Metric	Description
All Tables Compactions	Compaction	Number of table compactions. Compactions combine multiple HPE Data Fabric Database data files containing sorted data (known as spills) into a single spill file. This is displayed in the default chart view for all the tables.
All Tables Full Compactions		Number of full compactions. Compactions combine multiple HPE Data Fabric Database data files containing sorted data (known as spills) into a single spill file. Full compactions improve read performance because after compaction, HPE Data Fabric Database needs to read only the single resulting sorted spill file. But they incur I/O costs because the compaction must read, sort, and rewrite all data in the spill files.
All Tables Mini Compactions		Number of partial compactions. Compactions combine multiple HPE Data Fabric Database data files containing sorted data (known as spills) into a single spill file. After a mini compaction, HPE Data Fabric Database needs to read only two spill files.
All Tables TTL Compactions		Number of compactions that result in reclamation of disk space after removal of stale data. You can control the frequency of TTL compactions by configuring the TTL for a table's column families.
All Tables Free Index Memory	Memindex Usage	The number of available MB in the in-memory bucket file cache.

* Percentiles are estimated by linearly interpolating between fixed buckets sizes.

Loading Documents into JSON Tables

There are three command-line utilities for loading documents into JSON tables: `mapr copytable`, `mapr importtable` (which works in conjunction with the `mapr exporttable` utility), and `mapr importJSON`.

You can choose whether to have these utilities perform bulk loads or incremental loads.

For bulk loads, the `-bulkload` parameter of the JSON table must be set to `true`. During a bulk load, client applications are unable to access the table. After the utility is finished, you must set the table's `-bulkload` parameter to `false`, so that client applications can access the table again.

When you set the `-bulkload` parameter to `true`, you cannot enable replication on the table. Since this effectively disables logging on the table, HPE Data Fabric Database also does not capture log data that Elasticsearch can use to index the table.

NOTE: Incremental loads allow client applications to access the table as the documents are loaded. However, incremental loads are slower than bulk loads.

mapr copytable

The `mapr copytable` utility copies documents -- all documents or a subset determined by a range of row keys, and all fields or a subset of fields -- directly from one JSON table to another.

Figure 15: Copying a subset of data from one table to another

For reference information about this utility, see [mapr copytable](#).

mapr exporttable and mapr importtable

The `mapr exporttable` utility exports data from a JSON table to binary sequence files that you can import into another JSON table by using the `mapr importtable` utility.

Figure 16: JSON documents exported from a JSON table as binary sequence files and then imported into another JSON table

The destination directory is created by the `mapr exporttable` utility. To prevent accidental overwriting of data, the `mapr exporttable` utility fails if the destination directory already exists.

The command for running the `mapr importtable` utility in step 2 of the diagram above would look like this:

```
mapr importtable -src /data/* -dst /collection/artworks
```

The `-columns` parameter of the `mapr exporttable` utility lets you export subsets of the fields in the documents that are in a table. For example, to export field `b`, the fields under it, and field `d` from documents with the following structure, the command to run the `mapr exporttable` utility would look like this:

```
mapr exporttable -columns a.b,c.d -src /collection/all_data -dst /data
```

For reference information about these commands, see [HPE Data Fabric Database JSON ExportTable and ImportTable](#) on page 7436.

mapr importJSON

This utility imports one or more JSON documents that are text files into a JSON table.

Figure 17: JSON documents in a folder named `/data` being imported into a JSON table

If each document does not already contain an `_id` field to use as a document ID, the `mapr importJSON` utility adds an `_id` field during the import. Use the `-idfield` parameter to specify the name of the field that contains the value to copy into the value of the `_id` field.

For example, each document might have a `product_ID` field that contains a universally unique identifier. You could run the utility with this command:

```
mapr importJSON -idfield "product_ID" -src /data/* -dst /collection/artworks
```

For reference information about this command, see the `mapr importJSON` command.

Loading Data into Binary Tables

Bulkload operations can be performed as a full bulkload or as an incremental bulkload.

The most common way of loading data into a HPE Data Fabric Database Binary Tables is with a `put` operation. However, at large scales, bulk loads offer a performance advantage over `put` operations.

Bulk loading is supported by the following tools, which can be used for both full and incremental bulkload operations:

- Hbase *HPE Data Fabric Database Binary CopyTable* utility which copies HPE Data Fabric Database binary table data, table metadata, access control expressions, and more to another HPE Data Fabric Database binary table.

```
hbase com.mapr.fs.hbase.tools.mapreduce.CopyTable
```

- Hbase ImportFiles utility which imports HFile or Result files into HPE Data Fabric Database binary tables. For example:

```
hbase com.mapr.fs.hbase.tools.mapreduce.ImportFiles
-Dmapred.reduce.tasks=2
-inputDir < input directory, for example: /test/tabler.kv >
-table < table name, for example: /table2 >
[ -format < Result|HFile > ]
[ -sample < true|false > ]
[ -mapOnly < true|false > ]
```

Full Bulk Loads

Full bulkload operations offer the best performance advantage because it skips the write-ahead log (WAL) typical of HPE Data Fabric Database binary table operations. Full bulkload operations can only be performed on empty tables that have the bulkload attribute set to **true**. This value is set only when creating a table.

When you set the bulkload attribute, you cannot enable replication on the table. Since this effectively disables logging on the table, HPE Data Fabric Database also does not capture log data that Elasticsearch can use to index the table.

 **IMPORTANT:** Tables are unavailable for normal client operations, including put, get, and scan operations, while a full bulkload operation is in progress.

To create a HPE Data Fabric Database binary table for bulkloading, use one of the following:

- `maprccli table create` command with the `-bulkload` parameter set to `true`.
- Apache HBase shell `create` command with the `BULKLOAD` parameter set to `true`. For example:

```
hbase> create '/a0', 'f1', BULKLOAD => 'true'
```

If you want to pre-split a table, separate the `BULKLOAD` parameter from the `SPLITS` parameter. For example:

```
hbase> create '/t1', 'f1', {SPLITS => ['10', '20', '30']}, {BULKLOAD => 'true'}
```

- Control System with **Will table be bulkload?** option set to **Yes** under table **PROPERTIES**.

 **NOTE:** Attempting a full bulkload on a table that does not have the bulkload attribute set to `true` results in an incremental bulkload being performed instead.

After you perform a full bulkload on a table, you cannot perform a full bulkload on it again. For example:

- You cannot use the `maprccli table edit` command to set the `bulkload` parameter to `TRUE` again.
- You cannot use the Apache HBase shell `alter` command to set the `BULKLOAD` parameter to `TRUE` again.
- In the Control System, the **Will table be bulkload?** option cannot be modified after table creation.

Incremental Bulk Loads

Incremental bulk loads can add data to existing tables concurrently with other table operations, with better performance than put operations. This type of bulk load makes use of write-ahead log files.

NOTE: Tables are available for client operations, such as put, get, and scan operations, during incremental bulk loads.

You can use incremental bulk loads to ingest large amounts of data to an existing table. Tables remain available for standard client operations such as put, get, and scan while the bulk load is in process. A table can perform multiple incremental bulk load operations simultaneously.

NOTE: Whether you create a table with the `maprc li table create` command, with the `hbase shell's create` command, or in the Control System, incremental loads are supported by default.

Performing File System Operations on HPE Data Fabric Database Tables

The Data Fabric file system stores tables in the same namespace as files. You can move and delete tables in much the same way as you can with files. All file system operations remain accessible with the `hadoop fs` command.

Volume properties, such as replication factor or rack topology, that apply to the specified location also apply to tables stored at that location. You can move a table with the Linux `mv` command or the `hadoop fs -mv` command.

When you use Direct Access NFS or the `hadoop fs -ls` command to access a Data Fabric cluster, tables and files are listed together. Because the client's Linux commands are not table-aware, other Linux file manipulation commands, notably file read and write commands, are not available for HPE Data Fabric Database tables.

This section describes the operations that you can perform on HPE Data Fabric Database tables through a Linux command line when you access the cluster through NFS or with the `hadoop fs` commands.

Setting Permissions

HPE Data Fabric Database tables do not support setting user permissions through the UNIX `chmod` command or the `hadoop fs -chmod` analogue. Instead, HPE Data Fabric Database table access is controlled with Access Control Expressions (ACEs). See [Enabling Table and Stream Authorizations with ACEs](#) on page 1625.

Read and Write

You cannot perform read or write operations on a HPE Data Fabric Database table from a Linux file system context. For example, you cannot use the `cat` command to view the content of a table or search through a table with the `grep` command. file system returns an error when an application attempts to read or write to a HPE Data Fabric Database table.

Move

You can move a HPE Data Fabric Database table within a volume with the `mv` command over NFS or with the `hadoop fs -mv` command. These moves are subject to the standard permissions restrictions. Moves across volumes are not currently supported.

Remove

You can remove a table with the `rm` command over NFS or with the `hadoop fs -rm` command. These commands remove the table from the namespace and asynchronously reclaims the disk space. You can remove a directory that includes both files and tables with the `rm -r` or `hadoop fs -rmr` commands.

NOTE: To prevent users from deleting a particular table, you must ensure that users do not have WRITE permission on the folder in which the table is located. Permissions on the table itself are not used in evaluating whether a user can delete the table. This convention follows standard UNIX rules for file and directory permissions.

Copy and Recursive/Directory Copy

Table copying at the file-system level is not supported. See [Migrating Between Apache HBase Tables and HPE Data Fabric Database Tables](#) for information on copying tables using the HBase shell.

Managing Column Families and Columns

This section covers overviews of column families in binary tables and JSON tables, how to create column families, alter them, delete them, set permissions on them, and set and display parameter values.

For a conceptual overview of column families in binary tables, see *Column Families in Binary Tables*.

For a conceptual overview of column families in JSON tables, see *Managing Column Families*.

Creating Column Families

Explains how to create column families using either the Control System, the CLI, or the HBase shell.

About this task

There are several methods that you can use to create column families in HPE Data Fabric Database tables. To create column families, you must have the following permissions:

- [readAce](#) and [writeAce](#) on the volume
- [lookupdir](#) on directories in the path to the table
- `createrenamefamilyperm` on the table

Creating Column Families Using the Control System

About this task

To create a column family from the Control System, under **Data > Tables**:

NOTE: This option is not available on the Kubernetes version of the Control System.

Procedure

1. Click:
 - **Take me to Add Column Family** after creating a new table.
 - **Add Column Family** from the **All** pane of **Column Families** tab under the table information page.

See [Viewing Table Information](#) on page 1630.
2. Specify the following properties in the **Properties** pane of the **Add Column Family** page to set up a column family, as needed. See the table below for information on fields shown under the **Properties** pane of the **Add Column Family** page.

JSON Table Properties

Field	Field Description
Column Family Name	The name of the column family.

Field	Field Description
JSON Path	<p>The path to the column family in dotted notation. For example, suppose the table contained JSON documents that were of this general structure:</p> <pre> { "_id" : "ID", "a" : { "b" : { "c" : "value", }, "e" : "value" } } </pre> <p>If you want to create a column family at the field d nested within b, your new path would be a.b.d.</p> <p> NOTE: Ensure that the field at which you want to create the column family does not yet exist. If the field exists, it could become inaccessible after the column family is created.</p>
Compression	<p>The compression setting to use for the column family. Valid options are off, lzf, lz4, and zlib. The default setting is the same as the compression setting for the directory where the table is located.</p>

Field	Field Description
In Memory	<p>Determines whether preference is given to values of this column family for storage with row keys. Because row keys are cached in memory in preference to row data, column-family data that is stored inline with the row keys is also cached in memory.</p> <p>For all column families in a table together, up to 200 bytes of row data will be stored inline with each row key. Storing data inline with a row key might speed retrieval of the data from a column family because disk access can often be avoided. For each column family, up to 32 bytes can be stored inline with each row key even if this is disabled (No), but preference will be given to column families where this is enabled (Yes). A column family can have more than 32 bytes stored inline if this is enabled.</p> <p>If the total number of bytes for all column families together exceeds 200 for a row, then preference for inclusion within the inline storage for that row is given to column families that have this enabled.</p> <div> NOTE: All of the data for a column family will be stored in-line with the row key, or none will be. If the contents in a column family for a particular row are larger than the maximum number of bytes that are allowed to be stored for that column family, no data will be stored in-line for that column family.</div> <p>By default, this is enabled.</p>

Binary Table Properties

Field	Field Description
Column Family Name	The name of the column family.
Version	<ul style="list-style-type: none">• Minimum — The minimum number of versions of column values to keep. The default is zero.• Maximum — Maximum number of versions of column values to keep. The default is one.
Compression	The compression setting to use for the column family. Valid options are off, lz4, lz4hc, and zlib. The default setting is the same as the compression setting for the directory where the table is located.
Time-to-Live	Specifies whether to purge data when the age of the data in this column family exceeds the value specified here. Data can remain forever or can be purged after specified amount of time (in seconds). Setting the value to 0 is equivalent to allowing data to remain indefinitely or forever.

Field	Field Description
In Memory	<p>Determines whether preference is given to values of this column family for storage with row keys. Because row keys are cached in memory in preference to row data, column-family data that is stored inline with the row keys is also cached in memory.</p> <p>For all column families in a table together, up to 200 bytes of row data will be stored inline with each row key. Storing data inline with a row key might speed retrieval of the data from a column family because disk access can often be avoided. For each column family, up to 32 bytes can be stored inline with each row key even if this is disabled (No), but preference will be given to column families where this is enabled (Yes). A column family can have more than 32 bytes stored inline if this is enabled.</p> <p>If the total number of bytes for all column families together exceeds 200 for a row, then preference for inclusion within the inline storage for that row is given to column families that have this enabled.</p> <div> NOTE: All of the data for a column family will be stored in-line with the row key, or none will be. If the contents in a column family for a particular row are larger than the maximum number of bytes that are allowed to be stored for that column family, no data will be stored in-line for that column family.</div> <p>By default, this is enabled.</p>

3. (JSON Tables) Under the **Security Policy** pane, set the security policy for the displayed table column family, as needed:

- a) Open the **Security** pane of the page, if not already opened.
- b) Enter the name of or the first few characters of the name of an existing security policy in the **Search for security policy** field. Available policies matching your entry will be listed below the field.

NOTE: Tagging for the currently displayed table must be set to **Yes** to be able to use security policy options. All security policies are set up and created from the **Security** page.

- c) Click the checkbox next the name of the needed security policy, if listed. The selected policy is applied to the displayed table column family.
 - d) Click **Add** to the apply the security policy with its settings to the currently displayed table column family. The name of the security policy appears above the search box after you click **Add**.
4. Select **Basic** or **Advanced** to set up access controls (shown under the **User Access Control** pane) for the displayed column family, as needed. Note that the page options displayed after selecting **Basic** or **Advanced** differ. These differences are explained below. See the [JSON Table Data Access Control Permission Options](#) or [Binary Table Data Access Control Permission Options](#) tables below for permission descriptions.

NOTE: By default, all permissions are given to the user creating the table. You can use either the default permissions that are automatically displayed or proceed to define new permissions for this column family.

To grant or block access to users, groups, and/or roles, from the:

- **Basic** settings, select the type — public, (OR) user, group, or role — from the drop-down menu, specify the name of the user, group, or role, and select one or more checkbox to grant permissions.

TIP: Click to create a copy of the associated access control setting. Click to remove the associated access control expression.

To add [ACEs](#) for another user, group, or role, click **Add Another** and repeat this step.

- **Advanced** settings, specify public (p) or user (u), group (g), and/or role (r) who have or do not have the type of access using the following boolean expressions and subexpressions:
 - **!** — Negation operator.
 - **&** — AND operation.
 - **|** — OR operation.

Use (), parentheses, for subexpressions.

NOTE: You *cannot* specify user, group, or role individually if access is granted to all users (public).

Alternatively, click associated with the type of access to use the **Access Control Expression** window to define access for public or users, group, and/or role. See [Defining ACEs Using the Access Control Expression Builder](#) on page 2153 for more information.

NOTE: If you switch from **Basic** to **Advanced**, the basic settings, if any, are carried over to the advanced settings. If you switch from **Advanced** to **Basic**, all the settings are lost because the subexpressions and AND (&) and negation (!) operations that are supported by advanced settings are not supported in the basic settings.

JSON Table Data Access Control Permission Options

Option	Option Description
Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Traverse Data	<p>Can pass over fields in JSON documents. For example, suppose that a JSON table contains documents of this general structure:</p> <pre>{ "_id" : "ID", "a" : { "b" : "value", "c" : "value" } }</pre> <p>Suppose further that the user sjohnson has read permission on a.b, but not on a. For sjohnson to read a.b, the user needs the traverse permission on a. The user can then pass over field a to a.b. This permission is inherited by fields within the column family.</p>
Set Compression	Can set or change the compression setting for the column family.

Option	Option Description
Unmasked Data	Check Unmask Data to direct the system to show all data for the table column family for this new table. Leaving the Unmask Data unchecked directs the system to hide table column data when using this security policy for the selected user type.

Binary Table Data Access Control Permission Options

Option	Option Description
Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Append Data	Can do column appends. Column appends require permission both at the column-family level and at the column level.
Set Version	Can set or change the maximum and minimum number of versions of column values to keep.
Set Compression	Can set or change the compression setting for the column family.

- Click **Add Column Family** to add the column family to the table. The name of newly created column family appears in the **All** pane of the tables information page.
- Opt to [add field permissions](#) to the newly created column family.

Creating Column Families Using CLI or the REST API

About this task

JSON Table

To create a column family in a JSON table, include the parameters `-jsonpath` and `-force` :

```
maprcli table cf
create -path <path> -cfname
<name_of_column_family> -jsonpath
<path> -force true
```

For the full list of options, see the `table cf create` command.

The `-jsonpath` parameter specifies the path to the column family. The path is in dotted notation. For example, suppose the table contained JSON documents that were of this general structure:

```
{
  "_id" : "ID",
  "a" : {
    "b" : {
      "c" :
"value",
      "e" : "value"
    }
  }
}
```

You want to create a column family at the field `d` in the new path `a.b.d` because you plan to store image files in fields in that column family.

IMPORTANT: Ensure that the field at which you want to create the column family does not yet exist. Also ensure that there are no secondary indexes defined on the field. If the field does exist or is a field in an index, the data in the field could become inaccessible after you create the column family.

By default, every time you try to create a non-default column family in a JSON table, this command fails and returns a warning message that you should ensure there is no existing data at the specified path. Set the `-force` parameter to `true` if you want to override this warning mechanism and create a column family.

Binary Table

The command to create a column family for a binary table is:

```
maprcli table cf create -path
<path> -cfname <name_of_column_family>
```

For the full list of options for this command, see the `table cf create` command.

The format of the value of the `-path` parameter depends on whether you are creating a table on a local cluster or a remote cluster.

Creating a Column Family for a Binary Table Using HBase Shell

About this task

After starting the HBase shell, run the `alter` command. Type `help` to see a list of commands and their syntax.

Permission Types for Fields and Column Families in JSON Tables

By using ACEs, you can grant or deny access to fields and column families that are in JSON tables.

There are three types of permission:

- Traverse (`traverseperm`)
- Read (`readperm`)
- Write (`writeperm`)

Traverse (`traverseperm`)

This permission allows the grantee to descend a hierarchy of fields to access fields on which the grantee has write or read permission.

For example, suppose that a user has read and write access to only field `b` below.

To access field b, the user would need to be able to traverse (pass through) field a. In this case, because the entire document is in the default column family, the user could be granted traverse permission on the default column family. Field a would inherit the traverse permission.

If a user was denied traverse permission on the default column family, the user would not be able to access field b. Granting traverse permission on field a in this case would have no effect.

In the example below, field a is part of the cf1 column family.

To be able to read and write at field b, the user could be granted the traverse permission on the column family.

Read (readperm)

The read permission allows the grantee to read from a field.

This permission extends to fields that are nested below the field on which the permission was granted. However, grantees can be explicitly denied the permission on any of the nested fields.

Write (writeperm)

This permission allows the grantee to delete a field, insert a value into a field, or overwrite field value.

As illustrated in the two diagrams below, deleting a field also deletes all fields that are nested within that field, even those fields on which the write permission is explicitly denied.

*Obtaining readperm and writeperm on Fields*

In this scenario, you want to perform an operation on a field, and the operation requires that you have readperm and writeperm permissions on that field. How you obtain these permissions depends on whether the field is in the default column family or a non-default column family.

If the field is in the default column family

In the document below, you want to perform an operation on field c, which is in the default column family. The operation requires you to have `readperm` and `writeperm` on field c.

Figure 18: Schematic diagram of an JSON document in which all fields are in the default column family

Case 1: You have `readperm` and `writeperm` on the default column family

In this case, field c inherits these permissions, assuming that the permissions were not denied on field a or b.

If you do not have `readperm` and `writeperm` on field a or b, you need `traverseperm` on the field that denied you those permissions. You also need `readperm` and `writeperm` explicitly granted to you on field c. You could be granted these permissions with the `maprcli table cf colperm set` command, as in these examples:

```
maprcli table cf colperm set -path
<path to JSON table>
-cfname default -name
a.b -traverseperm u:<user ID> |
<existing ACE for this field>
maprcli table cf colperm set -path
<path to JSON table> -cfname default
```

```
-name a.b.c -readperm u:<user ID>
| <existing ACE for this
field> -writeperm
u:<user ID> | <existing ACE for this
field>
```

Case 2: You do not have `readperm` and `writeperm` on the default column family

In this case, you need the `traverseperm` permission on the default column family. Fields a and b inherit this permission. You also need `readperm` and `writeperm` on field c.

You could be granted these permissions with commands similar to these:

```
maprcli table cf edit -path
<path to JSON table> -cfname
default -traverseperm
u:<user ID> | <existing ACE for this
field>
maprcli table cf colperm set -path
<path to JSON table> -cfname
default -name a.b.c
-readperm u:<user ID> | <existing ACE
for this field> -writeperm u:<user
ID> |
<existing ACE for this field>
```

If the field is in a non-default column family

NOTE: Non-default column families are an advanced feature of HPE Data Fabric Database's native JSON support. For information about them, see [Column Families in JSON table](#).

In the following document, you want to perform an operation on field c, which is in the column family cf1 that is defined at field b with the path a . b.

Figure 19: Schematic diagram of an JSON document in which fields b and c are in a column family that has the path a.b

Case 1: You do not have readperm and writeperm on field b

You need traverseperm on field b and both readperm and writeperm on field c. You can be granted these permissions with commands similar to these:

```
/opt/mapr/bin/maprcli table cf
edit -path <path to JSON
table> -cfname cf1
-traverseperm u:<user ID> | <existing
ACE for this field>
maprcli table cf colperm set -path
<path to JSON table> -cfname
cf1 -name a.b.c
-readperm u:<user ID> | <existing ACE
for this field> -writeperm u:<user
ID> |
<existing ACE for this field>
```

Case 2: You do have readperm and writeperm on field b

You do not need any further permissions. Field c inherits your readperm and writeperm permissions from field b.

Obtaining readperm or writeperm on Fields

In this scenario, you want to perform an operation on a field, and the operation requires that you have readperm or writeperm permissions on that field. How you obtain either permission depends on whether the field is in the default column family or a non-default column family.

If the field is in the default column family

In the following document, you want to perform an operation on field *c*, which is in the default column family. The operation requires you to have readperm or writeperm on field *c*.

Figure 20: Schematic diagram of an JSON document in which all fields are in the default column family

Case 1: You have the same permission (readperm or writeperm) on the default column family

In this case, field *c* inherits the permission, assuming that the permission was not denied on field *a* or *b*.

If you do not have readperm or writeperm on field *a* or *b*, you need traverseperm on the field that denied you the permission that you need. You also need readperm or writeperm explicitly granted to you on field *c*.

Example commands to grant these permissions:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname
```

```
default -name a.b -traverseperm
u:<user ID> | <existing ACE for this
field>
```

The next example command grants readperm:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname
default -name a.b.c -readperm u:<user
ID> | <existing ACE for this field>
```

Case 2: You do not have the same permission (readperm or writeperm) on the default column family

In this case, you need the traverseperm permission on the default column family. You also need readperm or writeperm explicitly granted to you on field c.

Example commands to grant these permissions:

```
/opt/mapr/bin/maprcli table cf
edit -path <path to JSON
table> -cfname cf1
-traverseperm u:<user ID> | <existing
ACE for this field>
```

This next example command grants readperm:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname cf1
-name a.b.c -readperm u:<user ID> |
<existing ACE for this field>
```

If the field is in a non-default column family

NOTE: Non-default column families are an advanced feature of HPE Data Fabric Database's native JSON support. For information about them, see [Column Families in JSON Tables](#).

In the following document, you want to perform an operation on field c, which is in the column family that is defined at field b with the path a.b. The operation requires you to have readperm or writeperm on field c.

Figure 21: Schematic diagram of an JSON document in which fields b and c are in a column family that has the path a.b

Case 1: You do not have the permission you need (readperm or writeperm) on field b

You need traverseperm on field b, and you need readperm or writeperm granted to you explicitly on field c.

Example commands to grant these permissions:

```
/opt/mapr/bin/maprcli table cf
edit -path <path to JSON
table> -cfname cf1
-traverseperm u:<user ID> | <existing
ACE for this field>
maprcli table cf colperm set -path
<path to JSON table> -cfname cf1
-name a.b.c -readperm u:<user ID> |
<existing ACE for this field>
```

Case 2: You do have the permission you need (readperm or writeperm) on field b

You do not need any further permissions. Field c inherits your readperm and writeperm permissions from field b.

Setting Permissions on Arrays

If you are granting permissions on a field and the field contains array data, you must grant the permission on the array field. This grants access not only to array data in the field, but also nested documents and

scalar data. It is also possible to set permissions on subfields within nested documents that are stored in an array.

NOTE: This topic describes the behavior of permissions in HPE Data Fabric Database version 6.1 and later, regardless of the Data Fabric version you used to grant the permissions.

Granting Permissions on Array Elements

Suppose you have the following documents where person is:

- An array of nested documents in document id001
- A single nested document in document id002
- A scalar value in document id003

```
{
  "_id" : "id001",
  "person" : [
    {"name" : {"last" : "Smith", "first" : "John"}},
    {"name" : {"last" : "Subramaniam", "first" : "Ananya"}}
  ]
}
{
  "_id" : "id002",
  "person" : {"name" : {"last" : "Doe", "first" : "Jane"}}
}
{
  "_id" : "id003",
  "person" : "Unknown"
}
```

If you grant a user read permission on the array `person[]`, that user can read every field in every nested document within the array in document `id001`. The permission also enables the user to read the `person` field in documents `id002` and `id003`.

If you receive an error when trying to grant permission on `person[]` because you previously granted permission on `person`, then you (or an administrator with the appropriate permissions) must first remove the existing permission on `person`. If you expect the schema of the `person` field to evolve to include non-array and array data, then you should grant the permission on `person[]` rather than `person` to avoid having to remove the conflicting `person` permission.

You cannot grant permissions on individual elements in an array; for example: `person[1]`. Granting permission on an array enables access to the entire array.

Granting Permissions on Nested Document Fields in an Array

If you want to restrict read access to only specific fields in `person`, whether the field is an array of nested documents or a single nested document, perform the following steps:

1. Deny the user read permission on the array `person[]`.
2. Grant the user traverse permission on the array `person[]`.
3. Grant the user read permission on the specific fields.

For example, to grant the user read permission on only the first names in the nested documents for the third step, grant read permission on `person[].name.first`. The permission enables the user to read the field in all nested documents in documents `id001` and `id002`.

If permissions already exist on `person.name.first`, then all attempts to define permissions on `person[].name.first` fails. You (or an administrator with the appropriate permissions) must first remove the existing permission on `person.name.first`. Similar to the scenario described in the previous section, if you expect the schema of the `person` field to evolve to include individual nested documents as well as arrays of nested documents, then you should grant the permission on `person[].name.first` to avoid having to remove the conflicting permission.

If you already have permissions on `person[].name.first`, then attempting to define permissions on `person.name.first` fails. There is no need to add this permission.

Granting Permissions on JSON Tables

Summarizes the default ACEs for the supported ways of setting read, traverse, and write permissions.

The default permissions for column families are determined when tables are created. The default permissions for fields are inherited from the column family where the fields are located.

Action	Method	Permissions	Default Access-Control Expressions
Set default permissions on new column families when creating a JSON table.	Java API	-defaultreadperm -defaulttraverseperm -defaultwriteperm	u:<ID of the process>
	maprcli table create		u:<user ID of table creator>
	mapr dbshell		
	Control System		
Set default permissions on new column families when editing a JSON table.	maprcli table edit		Current ACEs
	Control System		
Set permissions on a column family when creating the column family.	maprcli table cf create	-readperm -traverseperm -writeperm -indexperm	ACEs for -defaultreadperm, -defaulttraverseperm, and -defaultwriteperm
	Control System		
Set permissions on a column family when editing the column family.	maprcli table cf edit		Current ACEs
	Control System		
Set permissions on individual fields.	maprcli table cf colperm set		Inherited from column family or parent field
	Control System		
Set the dynamic mask	maprcli table cf column datamask set	-defaultunmaskedreadperm -unmaskedreadperm	Set to the table creator
	maprcli table cf colperm set		
	maprcli table create		
	maprcli table edit		
	maprcli table cf create		
	maprcli table cf edit		
	maprcli table cf colperm set		
	Control System		

Listing Column Families

Explains how to view the column families for a table using either the Control System or the CLI.

Viewing Table Column Families Using the Control System

About this task

To view the column families for a table:

Procedure

- 1. Go to the table information page.
See [Viewing Table Information](#) on page 1630.
- 2. Click the **Column Families** tab.
The page displays the default permissions for the column families in the **Default Column Family Authorization** pane, and for each column family, the **All** pane displays:

Column Name	Column Description
Column Family Name	The name of the column family.
JSON Path	The JSON path for the column in the JSON file in dotted notation.
Compression	The compression scheme used for the column family.
Time-to-Live	The amount of time to keep the data in the column family.
In Memory	Whether or not this column value resides in memory.

Selecting the checkbox associated with the column family makes the **Remove Column Family** button available. You can:

- [Add](#) a column family to the table
- [Remove](#) a column family associated with the table

Viewing Table Column Families Using the CLI or REST API

About this task

The command to list the column families that are in a table is:

```
maprcli table cf list -path <path> -cfname <name_of_column_family>
```

The format of the value of the -path parameter depends on whether you are viewing a table on a local cluster or a remote cluster:

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named test under a volume with a mount point at /volume1, specify the following path: /volume1/test
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named customer under volume1 in the sanfrancisco cluster, specify the following path: /mapr/sanfrancisco/volume1/customer

 **NOTE:** You cannot use the following characters in the table name:

```
< > ? % \
```

To use the following characters in the table name, enclose them either in single or double quotes:

```
; | ( ) /
```

For example:

```
maprcli table create -path "/^=#{ }&()/" (or)
maprcli table create -path '/^=#{ }&()/'
```

To use either the ' or the " character in the table name, enclose:

- the ' character within double quotes (")
- the " character within single quote (')

For example:

```
maprcli table create -path "'^=#{ }&()/" (or)
maprcli table create -path '"^=#{ }&()/'
```

To run this command, your user ID must have the following permissions:

- readAce on the volume
- lookupdir on directories in the paths
- adminaccessperm on the table

For complete reference, see the `table cf list` command.

Removing Column Families

Explains how to delete column families using either the Control System or the CLI.

About this task

 **IMPORTANT:** Starting in the 6.0 release, you cannot delete a column family from a JSON table.

Removing Column Families Using the Control System

About this task

To remove one or more column families:

Procedure

1. Go to the table information page.
See [Viewing Table Information](#) on page 1630.
2. Click **Column Families** tab.
The page displays:
 - Default column family permissions
 - All the column families for the table
3. Select the checkbox associated with the column families to delete in the **All** pane.
4. Click **Remove Column Family**.
The **Remove Column Families** confirmation dialog displays.

5. Verify the list of column families and click **Remove Column Family**.

If necessary, click  to remove a column family from the list of column families to delete.

Removing a Column Family Using the CLI or the REST API

About this task

To remove a column family by name using the CLI or the REST API, run the following command:

```
maprcli table cf delete -path <path> -cfname <name>
```

See the `table cf delete` command for more information.

Altering Column Families

Explains how to modify the permissions and properties of column families using either the Control System, the CLI, or the HBase shell.

About this task

There are several methods that you can use to edit column families in HPE Data Fabric Database tables. These methods also let you change permissions on column families.

Modifying a Column Family Using the Control System

Procedure

1. Go to the table information page.
See [Viewing Table Information](#) on page 1630.
2. Click the **Column Families** tab.
The page displays the:
 - **Default Column Family Authorization** pane
 - **All** pane which lists the column families for the table
3. Click the name of the column family to modify.
The **Edit Column Family** page appears.
4. Make changes to the following properties (under the **PROPERTIES** pane), as desired.

JSON Table Properties

Field Name	Field Description
Column Family Name	The name of the column family.
Compression	The compression setting to use for the column family. Valid options are off, lzf, lz4, and zlib. The default setting is the same as the compression setting for the directory where the table is located.

Field Name	Field Description
In Memory	<p>Determines whether preference is given to values of this column family for storage with row keys. Because row keys are cached in memory in preference to row data, column-family data that is stored inline with the row keys is also cached in memory.</p> <p>For all column families in a table together, up to 200 bytes of row data will be stored inline with each row key. Storing data inline with a row key might speed retrieval of the data from a column family because disk access can often be avoided. For each column family, up to 32 bytes can be stored inline with each row key even if this is disabled (No), but preference will be given to column families where this is enabled (Yes). A column family can have more than 32 bytes stored inline if this is enabled.</p> <p>If the total number of bytes for all column families together exceeds 200 for a row, then preference for inclusion within the inline storage for that row is given to column families that have this enabled.</p> <div> NOTE: All of the data for a column family will be stored in-line with the row key, or none will be. If the contents in a column family for a particular row are larger than the maximum number of bytes that are allowed to be stored for that column family, no data will be stored in-line for that column family.</div> <p>By default, this is enabled.</p>

Binary Table Properties

Field Name	Field Description
Column Family Name	The name of the column family.
Version	<ul style="list-style-type: none"> Minimum — The minimum number of versions of column values to keep. The default is zero. Maximum — Maximum number of versions of column values to keep. The default is one.
Compression	The compression setting to use for the column family. Valid options are off, lz4, lz4, and zlib. The default setting is the same as the compression setting for the directory where the table is located.
Time-to-Live	Specifies whether to purge data when the age of the data in this column family exceeds the value specified here. Data can remain forever or can be purged after specified amount of time (in seconds). Setting the value to 0 is equivalent to allowing data to remain indefinitely or forever.

Field Name	Field Description
In Memory	<p>Determines whether preference is given to values of this column family for storage with row keys. Because row keys are cached in memory in preference to row data, column-family data that is stored inline with the row keys is also cached in memory.</p> <p>For all column families in a table together, up to 200 bytes of row data will be stored inline with each row key. Storing data inline with a row key might speed retrieval of the data from a column family because disk access can often be avoided. For each column family, up to 32 bytes can be stored inline with each row key even if this is disabled (No), but preference will be given to column families where this is enabled (Yes). A column family can have more than 32 bytes stored inline if this is enabled.</p> <p>If the total number of bytes for all column families together exceeds 200 for a row, then preference for inclusion within the inline storage for that row is given to column families that have this enabled.</p> <p> NOTE: All of the data for a column family will be stored in-line with the row key, or none will be. If the contents in a column family for a particular row are larger than the maximum number of bytes that are allowed to be stored for that column family, no data will be stored in-line for that column family.</p> <p>By default, this is enabled.</p>

5. (JSON Tables) Add or remove a security policy, as appropriate:

- **Add a Policy:**

- Enter the first few characters of the name of an existing security policy in the **Search for security policy** field. A list of security policies matching your search criteria are listed below the **Search for security policy** field.
- Check the needed policy.
- click **Add**. The added security policy appears above the **Search for security policy** field. The policy settings for the selected security policy are now associated with the column family.

- **Remove a Policy:** Click  (Delete) to the right of the displayed security name to remove disassociate the policy from the column family. The security policy is deleted immediately.

6. Do one of the following:

- Delete a set of user access control permissions:

Click  (Delete) to the right of a displayed set of permissions to delete the set of permissions. The set of user access control permissions are deleted immediately.

- Change or update one or more sets of existing user access control permissions:

See the tables below for more information on user access control permission options.

Use the **Basic** or **Advanced** settings to update existing permissions:

To grant or block access to users, groups, and/or roles, from the:

- **Basic** settings, select the type — public, (OR) user, group, or role — from the drop-down menu, specify the name of the user, group, or role, and select one or more checkbox to grant permissions.

TIP: Click  to create a copy of the associated access control setting. Click  to remove the associated access control expression.

To add **ACEs** for another user, group, or role, click **Add Another** and repeat this step.

- **Advanced** settings, specify public (p) or user (u), group (g), and/or role (r) who have or do not have the type of access using the following boolean expressions and subexpressions:

- **!** — Negation operator.
- **&** — AND operation.
- **|** — OR operation.

Use **()**, parentheses, for subexpressions.

NOTE: You *cannot* specify user, group, or role individually if access is granted to all users (public).

Alternatively, click  associated with the type of access to use the **Access Control Expression** window to define access for public or users, group, and/or role. See [Defining ACEs Using the Access Control Expression Builder](#) on page 2153 for more information.

NOTE: If you switch from **Basic** to **Advanced**, the basic settings, if any, are carried over to the advanced settings. If you switch from **Advanced** to **Basic**, all the settings are lost because the subexpressions and AND (&) and negation (!) operations that are supported by advanced settings are not supported in the basic settings.

JSON Table Permission Option Descriptions

Modify or update the following user access control permissions for the column family:

Option	Option Permission
Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Traverse Data	<p>Can pass over fields in JSON documents. For example, suppose that a JSON table contains documents of this general structure:</p> <pre>{ "_id" : "ID", "a" : { "b" : "value", "c" : "value" } }</pre> <p>Suppose further that the user sjohnson has read permission on a.b, but not on a. For sjohnson to read a.b, the user needs the traverse permission on a. The user can then pass over field a to a.b. This permission is inherited by fields within the column family.</p>
Set Compression	Can set or change the compression setting for the column family.

Option	Option Permission
Unmasked Data	Leaving the Unmask Data checkbox unchecked hides table column family data from the selected user. Checking the box allows the selected user to see all table data, based on and in coordination with other security and data access settings.

Binary Table Permission Option Descriptions

Modify or set the following permissions for the column family:

Option	Option Permission
Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Append Data	Can do column appends. Column appends require permission both at the column-family level and at the column level.
Set Version	Can set or change the maximum and minimum number of versions of column values to keep.
Set Compression	Can set or change the compression setting for the column family.

- Click **Save Changes** for the changes to take effect.

Modifying a Column Family Using the CLI or REST API

About this task

The basic command to edit a column family is:

```
maprcli table cf edit -path <path> -cfname <name_of_column_family> options
```

For the full list of options, see the `table cf edit` command.

The format of the value of the `-path` parameter depends on whether you are creating a table on a local cluster or a remote cluster:

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customer`

NOTE: You cannot use the following characters in the table name:

```
< > ? % \
```

To use the following characters in the table name, enclose them either in single or double quotes:

```
; | ( ) /
```

For example:

```
maprccli table create -path "/^=#{ }&()/" (or)
maprccli table create -path '/^=#{ }&()/'
```

To use either the `'` or the `"` character in the table name, enclose:

- the `'` character within double quotes (`"`)
- the `"` character within single quote (`'`)

For example:

```
maprccli table create -path "/"'^=#{ }&()/" (or)
maprccli table create -path '/'"'^=#{ }&()/'
```

Modifying a Column Family in a Binary Table Using HBase shell

About this task

After starting the HBase shell, run the `alter` command. Type `help` to see a list of commands and their syntax.

Related tasks

Displaying Default Column Family Permissions

Use either the Control System or the `maprc li` command to find out the users, groups, or roles that have permissions on the default column family.

Viewing Default Column Family Permissions in the Control System

Procedure

- Log in to the Control System and go to the **Column Families** tab from the [table information page](#).
The **Default Column Family Authorization** pane displays the following permissions for users, groups, and roles.

Binary Table Default Column Family Authorization Permissions

Permission	Permission Description
Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Append Data	Can do column appends. Column appends require permission both at the column-family level and at the column level.
Set Version	Can set or change the maximum and minimum number of versions of column values to keep.
Set Compression	Can set or change the compression setting for the column family.

JSON Table Default Column Family Authorization Permissions

Permission	Permission Description
Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.

Permission	Permission Description
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Traverse Data	<p>Can pass over fields in JSON documents. For example, suppose that a JSON table contains documents of this general structure:</p> <pre> { "_id" : "ID", "a" : { "b" : "value", "c" : "value" } } </pre> <p>Suppose further that the user sjohnson has read permission on a . b, but not on a. For sjohnson to read a . b, the user needs the traverse permission on a. The user can then pass over field a to a . b. This permission is inherited by fields within the column family.</p>
Set Compression	Can set or change the compression setting for the column family.
Unmasked Data	Can perform unmasked column reads if the user also has read data permission. Unmasked data require permission both at the column family level and at the field level. This permission is inherited by fields within the column family.

Retrieving the Default Column Family Permissions Using the CLI

About this task

To display the permissions on a column family, run this command:

```
maprcli table cf colperm get -path <path> -cfname <name of column family> -json
```

To display the permissions on a column, add the `-name` parameter:

```
maprcli table cf colperm get -path <path> -cfname <name of column family> -name <name of column> -json
```

The format of the value of the `-path` parameter depends on whether you are viewing a table on a local cluster or a remote cluster.

The `json` parameter displays the output as a JSON document.

Managing Column Family Fields and Field Permissions for JSON Tables

This section covers details for working with column family fields. Column family fields can be added to any existing JSON table, and column families comprise optional fields.

Adding Field Permissions to a JSON Table Column Family

Explains how to add fields and field permissions to a column family for a specified JSON table using the Control System.

About this task

Use the Control System to add field permissions to an existing table with a column family.

NOTE: Field and field permissions can be used with and assigned to only JSON tables.

Procedure

1. Log into the Control System using your login credentials. The Control System **Overview** page appears.

NOTE: This option is not available on the Kubernetes version of the Control System.

2. Click **Data > Tables** from the top of the page. The **Tables** page appears.
3. Select the JSON table needing field permissions added from the **Recently Viewed Tables** pane or enter the path to the needed table in the available field, and then click **Go**. The table information page of the selected table appears.
4. Click the **Column Families** tab. A page showing column family information appears.
5. Click the name of column family (under the **All** pane) to which field permissions are to be added, and then click **Field Permission** at the top of the **Edit Column Family** page. A new page appears showing existing fields, if any, in the left pane. If none, the **FIELD AUTHORIZATION - ACCESS CONTROL EXPRESSION** pane allows you to add a field to the column family.
6. Click **Add Field** (if displayed) to add a field. The default Field description appears in the **Field Name** field.
7. Replace the Field entry in the **Field Name** field by entering a new name for the new field, as applicable.

8. Click the **Data Masking** pull-down menu (shown near to top of the page in the right pane), and then select one of the following data masking options, as needed:
 - Replace all alpha characters with an X and numeric characters with 0,
 - Show only the last 4 characters. Replace all other characters with an 'x',
 - Show only the first 4 characters. Replaces all other characters with an 'x',
 - Show only the first 6 and last 4 characters. Replaces other characters with an 'x',
 - Show the first and last 2 chars of username and part of domain,
 - Show the hash of the data, or
 - Shows only the year portion of the date and default everything else to Jan 1 and 00:00:00
 - None
9. Set user access control permissions for the currently selected field by doing one of the following:
 - Select **Basic**, and then select a user type from the **Type** pull-down menu, enter a name for the user type in the **Name** field, and check data access permissions, as needed.
 - Select **Advanced**, and then enter the permission details, and, if necessary, click  (the pencil icon) to open the **Edit Data Access Control Expression** window to select additional permission definitions. See [Defining ACEs Using the Access Control Expression Builder](#) on page 2153 for more information.

NOTE: The **AUTHORIZATION - ACCESS CONTROL EXPRESSION** pane of the page displays default column family authorizations as a reference.

Field Permission Descriptions (for JSON Tables)

By default, a field inherits permissions from the column in which the field is located. Permissions set at this level override permissions inherited from the column. You can set the following permissions by selecting the associated checkbox, as described in the table below.

Read Data	Can read from the field. This permission extends to fields that are nested below as well unless explicitly denied on any of the nested fields.
Write Data	Can delete the field, insert a value into the field, or overwrite the field's value.  NOTE: Deleting a field also deletes all fields that are nested within that field, even those fields on which the write permission is explicitly denied.

Traverse Data	Can descend a hierarchy of fields to access the fields to read or write.
Unmasked Data	Check Unmask Data to allow the specified user to see all field data for field specified of the selected column family. Leaving the Unmask Data field unchecked hides field data for the selected column family from the selected user.

By default, all permissions are given to the user creating the table.

10. Opt to repeat the [step above](#) to:

- Add another field by clicking **Add Field**.
- Add a different set of permissions to a selected field for another public user or another user, group, or role.

11. Click **Save Changes** to save your current additions and changes.

Explains how to modify the permissions and properties of column families using either the Control System, the CLI, or the HBase shell.

[Adding Field Permissions to a JSON Table Column Family](#) on page 1686

Explains how to add fields and field permissions to a column family for a specified JSON table using the Control System.

Editing Field Permissions for a JSON Table Column Family

Explains how to edit field permissions for an existing column family for a specified JSON table using the Control System.

About this task

Use the Control System to edit field permissions for fields that are part of a column family within an existing JSON table.

NOTE: Field and field permissions can be used with and assigned to only JSON tables.

Procedure

1. Log into the Control System using your login credentials. The Control System **Overview** page appears.

NOTE: This option is not available on the Kubernetes version of the Control System.

2. Click **Data > Tables** from the top of the page. The **Tables** page appears.

3. Select the JSON table needing field permissions edited by selecting it under the **Recently Viewed Tables** pane or entering the path to the needed table in the available field, and then clicking **Go**. The table information page of the selected table appears.
4. Click the **Column Families** tab.
5. Click the name of the column family (under the **All** pane) to which field permissions are to be edited, and then click **Field Permission** at the top of the **Edit Column Family** page.
6. Opt to:
 - Add additional fields:
 - a. Click **Add Field** to add one or more fields, and then select a field listed in the left-hand pane of the screen.
 - b. Enter a name for the field in the **Field Name** field, as applicable.
 - Change the name of an existing field of the displayed column family by clicking on the name of the field (in the left panel) and then updating the name in the **Field Name** field.
 - Delete an existing field by clicking  (delete) to the right of the field name shown in the left pane of the page. The field name is deleted immediately.
 - Change data masking options for a selected field:

Select the field to have its masking options modified, and then click the **Data Masking** pull-down menu, and then select one of the following data masking options:

 - Replace all alpha characters with an X and numeric characters with 0,
 - Show only the last 4 characters. Replace all other characters with an 'x',
 - Show only the first 4 characters. Replaces all other characters with an 'x',
 - Show only the first 6 and last 4 characters. Replaces other characters with an 'x',
 - Show the first and last 2 chars of username and part of domain,
 - Show the hash of the data, or
 - Shows only the year portion of the date and default everything else to Jan 1 and 00:00:00
 - None
 - Change existing access permission selections for the currently displayed field or add a new set of access permissions for the selected field by clicking on the name of the field in the left panel and then selecting either of the following:
 - **Basic**. After selecting **Basic**, click **Add Another** and make selections and entries for a new set of permissions. Alternatively, for a listed user type, select a different user type from the **Type** pull-down menu, , change the name for the user type in the **Name** field, and update access permissions, as needed. See the table below for permission option information.

 **NOTE:** Alternatively, you can click  (Duplicate) to duplicate the previously listed row and then select applicable permissions.
 - **Advanced**. After selecting **Advanced**, enter the permission details, and, if necessary, click  (the pencil icon) to open the **Edit Data Access Control Expression** window to select additional permission definitions. See [Defining ACEs Using the Access Control Expression Builder](#) on

page 2153 for more information on ACE functionality. See the table below for access permission option information.

NOTE: The **AUTHORIZATION - ACCESS CONTROL EXPRESSION** pane of the page displays default column family authorizations (just below the **Data Masking** pull-down menu) as a reference.

Field Permissions (for JSON Tables)

By default, a field inherits permissions from the column in which the field is located. Permissions set at this level override permissions inherited from the column. You can set the following permissions by selecting the associated checkbox, as described in the table below.

Read Data	Can read from the field. This permission extends to fields that are nested below as well, unless explicitly denied on any of the nested fields.
Write Data	Can delete the field, insert a value into the field, or overwrite the field's value.  NOTE: Deleting a field also deletes all fields that are nested within that field, even those fields on which the write permission is explicitly denied.
JSON Traverse	Can descend a hierarchy of fields to access the fields to read or write.
Unmasked Data	Check Unmask Data to allow the specified user to see all field data for field specified of the selected column family. Leaving the Unmask Data field unchecked hides field data for the selected column family from the selected user.

By default, all permissions are given to the user creating the table. See [Permission Types for Fields and Column Families in JSON Tables](#) on page 1662 for more information.

- Delete an existing set of permissions for a created user type of a select field:
 - a. Click on the name of the field associated with the permissions to be deleted.

- b. Click  (Delete) to the far right of the permission options. The set of permissions is deleted immediately.

7. Opt to:

- Add another field by clicking **Add Field**. See the [above step](#) for more details.
- Update data masking options for another field. See the [above step](#) for more details.
- Add a different set of permissions to a selected field for another public user or another user, group, or role. See the [above step](#) for more details.
- Delete another set of permissions for a listed user type. See the [above step](#) for more details.

8. Click **Save Changes** to save your current additions and changes.

Viewing Fields and Field Permissions for a JSON Table Column Family

Explains how to view field and field permissions for an existing JSON table.

About this task

This task explains how to access JSON table column family fields and field permissions.

NOTE: Field and field permissions can be used with and assigned to only JSON tables.

Procedure

1. Log into the Control System using your login credentials. The Control System **Overview** page appears.

NOTE: This option is not available on the Kubernetes version of the Control System.

2. Click **Data > Tables** from the top of the page. The **Tables** page appears.
3. Select the JSON table associated with the fields you want to view by selecting it under the **Recently Viewed Tables** section or entering the path to the needed table in the available field, and then clicking **Go**. The table information page of the selected table appears.

4. Select the **Column Families** tab.
5. Click the name of the column family (under the **All** section). The **Edit Column Family** page appears.
6. Click **Field Permission** at the top of the **Edit Column Family** page. The page displays a listing of fields associated with the selected column family, if any, in the left pane, and all permissions associated with the selected field are displayed at the bottom of the page. You can select any listed field to view its permission.

NOTE: If no column family fields appear, then none have been set up. See [Adding Field Permissions to a JSON Table Column Family](#) on page 1686 for more information on setting up fields for a column family.

Managing Table Replication

This section contains topics about setting up table replication and administering existing replicas.

The process to set up table replication consists of the following steps:

1. [Select a Topology](#)
2. [Prepare Clusters for Table Replication](#).
3. Set up Table Replication using one of the following options:
 - [Run maprccli table replica autoseup.](#)
 - [Add a Table Replica in the Control System.](#)

1. [Select a Table Topology](#)
2. [Prepare Clusters for Table Replication](#)
3. [Run maprccli table replica autoseup](#)
4. [Add a Table Replica in the MCS](#)

NOTE: After setting up replication, replicas can be administered using either the Control System or the CLI.

Preparing Clusters for Table Replication

Preparing clusters for table replication includes configuring gateways on destination clusters, configuring the `mapr-clusters.conf` file on the source cluster, and, if the clusters are secure, setting up secure communications between the clusters. After you prepare the clusters for table replication, you can setup replication between tables.

Before You Begin

The following topics identify concepts and tasks that you need to do before setting up your environment for table replication.

- Plan which replication topology you want to use. For information about the various topologies, see [Supported replication topologies](#) on page 821.

- In general, if you are replicating tables, you should store them in their own volumes to avoid overlap with volume mirroring. Otherwise, if a source volume fails, you may have a scenario where a table in a promoted mirror lags behind the table's replica.

For example, suppose /vol mirrors to /vol.mirror and contains a table srcTab that replicates to /replVol/replTab. If /vol fails, /vol.mirror/srcTab may lag /replVol/replTab when /vol.mirror is promoted.

To avoid this problem, starting with the 6.1 release, after HPE Data Fabric Database promotes a mirror volume, replication terminates with REPLICATION_STATE_UNEXPECTED for any tables in that volume.

The following sample output shows this behavior:

```
[mapr]# /opt/mapr/bin/maprccli table replica list -path /vol.mirror/
srcTab -refreshnow true -json
{
  "timestamp":1534805233244,
  "timeofday":"2018-08-20 03:47:13.244 GMT-0700 PM",
  "status":"OK",
  "total":1,
  "data":[
    {
      "cluster":"mirrorSrc",
      "table":"/replVol/replTab",
      "type":"MapRDB",
      "replicaPath":"/replVol/replTab",
      "replicaState":"REPLICATION_STATE_UNEXPECTED",
      "paused":false,
      "throttle":false,
      "idx":1,
      "networkencryption":false,
      "synchronous":false,
      "networkcompression":"lz4",
      "propagateExistingData":false,
      "isUptodate":true,
      "minPendingTS":0,
      "maxPendingTS":0,
      "bytesPending":0,
      "putsPending":0,
      "bucketsPending":0,
      "uuid":"8b4563e1-884d-7852-f257-078c397b5b00",
      "copyTableCompletionPercentage":0,
      "errors":{
        "Code":"ErrReplicaTableUpstreamMismatch",
        "Host":"10.10.104.35",
        "Msg":"OpenStream: Upstream table does not match original
Upstream cluster mirrorSrc table /replVol/replTab"
      }
    }
  ]
}
```

This change in behavior applies to only tables that have replication enabled starting in 6.1. See [Table Replication States](#) on page 835 for more details.

- Ensure that your user ID has the readAce permission on the volume where the source tables are located and the writeAce permission on the volumes where the replicas are located. For information about how to set permissions on volumes, see [Setting Whole Volume ACEs](#) on page 1627.
- Ensure that you have administrative authority on the clusters that you plan to use.

- If you upgraded your source cluster from a previous version of Data Fabric, enable table replication by running this `maprccli` command: `maprccli cluster feature enable -name mfs.feature.db.repl.support`
- Depending on your use case, replication requires the installation of gateways and may also require the HBase client. For more information about installation requirements, see [Service Layout Guidelines for Replication](#) on page 86

Setting Up Table Replication

The following steps show how to set up your environment for table replication including setup for secure clusters.

1. In the `mapr-clusters.conf` file on every node in your source cluster, add an entry that lists the CLDB nodes that are in the destination cluster. This step is required so that the source cluster can communicate directly with the destination cluster's CLDB nodes. See [mapr-clusters.conf](#) for the format to use for the entries.
2. On the destination cluster, configure gateways through which the source cluster sends updates to the destination cluster. See [Configuring Gateways for Table and Stream Replication](#) on page 1789.
3. If your clusters are secure, configure each cluster so that you can access them all from one cluster. This way, you need not log into each secure cluster separately and run `maprccli` commands locally on them. See [Configuring Secure Clusters for Running Commands Remotely](#) on page 2223 for more information.
4. If your clusters are secure, add a cross-cluster ticket to the source cluster, so that it can replicate data to the destination cluster. See [Configuring Secure Clusters for Cross-Cluster Mirroring and Replication](#) on page 2226.
5. **Optional:** If your clusters are secure, configure your source cluster so that you can use the Control System to set up and administer table replication from the source to the destination cluster.

These steps make it convenient to use the Control System for setting up and managing replication involving two secure clusters. However, before following them, perform these prerequisite tasks.

NOTE:

- Ensure that both clusters are managed by the same team or group. The UIDs and GIDs of the users that are able to log in to the Control System on the source cluster must exactly match their UIDs and GIDs on the destination cluster. This restriction applies only to access to both clusters through the Control System, and does not apply to access to both clusters through the `maprccli`. If the clusters are managed by different teams or groups, use the `maprccli` instead of the Control System to set up and manage table replication involving two secure clusters.
- Ensure that the proper file-system and table permissions are in place on both clusters. Otherwise, any user who can log into the Control System and has the same UID or GID on the destination cluster will be able to set up replication either from the source cluster to the destination cluster or vice versa. A user could create one or more tables on the destination cluster, enable replication to them from the source cluster, load the new tables with data from the source cluster, and start replication. A user could also create tables on the source cluster, enable replication to them from tables in the destination cluster, load the new tables with data from the destination cluster, and start replication.

- a. On the source cluster, generate a service ticket by using the `maprlogin` command:

```
maprlogin generateticket -type service -cluster <destination cluster>
-user mapr -duration <duration> -out <output folder>
```

Where `-duration` is the length of time before the ticket expires. You can specify the value in either of these formats:

- `[Days:]Hours:Minutes`
- `Seconds`

- b. To every node of the source cluster, add the service ticket to the file `/opt/mapr/conf/mapruserticket` file that was created when you secured the source cluster:

```
at <path and filename of the service ticket> >> /opt/mapr/conf/
mapruserticket
```

- c. Restart the web server by running the `maprccli node services` command. For the syntax of this command, see [node services](#) on page 2598.
- d. Add the following two properties to the `core-site.xml` file. For Hadoop 2.7.0, edit the file `/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/core-site.xml`.

```
<property>
  <name>hadoop.proxyuser.mapr.hosts</name>
  <value>*</value>
</property>
<property>
  <name>hadoop.proxyuser.mapr.groups</name>
  <value>*</value>
</property>
```

Setting Up Table Replication Using the CLI

You can run the `maprccli table replica autose setup` command to set up primary-secondary or multi-master replication from an existing source table.

Prerequisites

NOTE: This procedure describes how to use the `maprccli` to automatically set up table replication. As an alternative, you can use the [Control System to automatically setup table replication](#) or use the `maprccli` command to [manually setup primary-secondary replication](#) or [manually setup multi-master replication](#).

Before you begin, complete the following steps:

- Verify that you have completed the steps to configure the clusters for table replication. For more information, see [Preparing Clusters for Table Replication](#) on page 1693.
- On the source table, run the `maprccli table info` command to verify that you have the following permissions:
 - `readperm`, which is required for reading from the table.
 - `replperm`, which is required for replicating from the table.

On the destination table (if it already exists), run the `maprccli table info` command to verify that you have the following permissions:

- `bulkload`, which is required for the initial copy of source data into the destination table.
- `replperm`, which is required for receiving replicated updates from the source table.

All updates from a source table arrive at a replica after having been authenticated at a gateway. Therefore, access control expressions on the replica that control permissions for updates to column families and columns are irrelevant; gateways have implicit authority to update replicas.

About this task

NOTE: If you are setting up a primary-secondary replication loop for n clusters, repeat these steps for $n-1$ primary-secondary relationships to set up basic primary-secondary topologies.

Procedure

1. Log into both the source and destination clusters.
2. Run the `maprcli table replica autoseup` command.
 - For primary-secondary replication:

```
maprcli table replica autoseup -path /mapr/<source cluster>/<path to table> -replica /mapr/<destination cluster>/<path to table>
```

- For multi-master replication:

```
maprcli table replica autoseup -path /mapr/<source cluster>/<path to table> -replica /mapr/<destination cluster>/<path to table> -multimaster true
```

NOTE:

The parameter `-multimaster` is an optional parameter that you use to set up multi-master replication.

For example, to set up multi-master replication between the `customers` table in the `sanfrancisco` cluster and a new `customers` table in the `newyork` cluster, you could use this command:

```
maprcli table replica autoseup -path /mapr/sanfrancisco/customers -replica /mapr/newyork/customers -multimaster true
```

To set up primary-secondary replication between the `customersA` table in the `sanfrancisco` cluster and a new `customersB` table in the same cluster, you could use this command:

```
maprcli table replica autoseup -path /mapr/sanfrancisco/customersA -replica /mapr/sanfrancisco/customersB
```

NOTE: For information about additional parameters that you can configure, see [table replica autoseup](#) on page 2844.

3. To check the replication status, run [table replica list](#) on page 2853.

What to do next

Additional Information:

- With multi-master replication, if one of the tables goes offline, you can direct client applications to the other table. For more information, see [Multi-Master Replication](#) on page 826.
- Be aware that changes to the structure of a source table are not replicated automatically to replicas. For more information, see [Adding a Column Family to a Replica](#) on page 1714
- Check the Control System for alarms related to replication and whether synchronous replication is switched temporarily to asynchronous replication. See [Table-Replication Alarms](#).

Setting Up Primary-Secondary Replication Manually

You can run `maprc li` commands to set up primary-secondary replication manually.

Procedure

1. Ensure that you have followed these prerequisite steps:
 - Verify that you have complete the steps to configure the clusters for table replication. For more information, see [Preparing Clusters for Table Replication](#) on page 1693.
 - Run the `maprc li table info` command on the source table to verify that you have the following permissions:
 - `readperm`, which is required for reading from the table.
 - `replperm`, which is required for replicating from the table.
 - Run the `maprc li table info` command on the destination table (if it already exists) to verify that you have the following permissions:
 - `bulkload`, which is required for the initial copy of source data into the destination table.
 - `replperm`, which is required for receiving replicated updates from the source table.
2. Create the replica manually with the `maprc li` command `table create`. Use the `-copymetafrom` option to ensure that the metadata for the replica is identical to the metadata for the source table. Metadata includes column families, access control expressions (ACEs), and other attributes.

```
maprc li table create -path <path to the replica> -copymetafrom <path to the source table>
```

For example, to create the replica `customers` in the `newyork` cluster and use the metadata from the source table in the `sanfrancisco` cluster, you could use this command:

```
maprc li table create -path /mapr/newyork/customers -copymetafrom /mapr/sanfrancisco/customers
```

3. Register the replica as a replica of the source table by running the `maprccli table replica add` command.

```
maprccli table replica add -path <path to the source table> -replica
<path to the replica> -paused true
```

For example, to register the `customers` table in the `newyork` cluster as a replica of the `customers` table in the `sanfrancisco` cluster, you could use this command:

```
maprccli table replica add -path /mapr/sanfrancisco/customers -replica /
mapr/newyork/customers -paused true
```

The `-paused` parameter ensures that replication does not start immediately after you register the source table as a source for this replica. You do this registration in step 4.

NOTE: For more information about additional parameters that you can configure, see [table replica add](#) on page 2841.

4. Verify that you specified the correct replica by running the `maprccli table replica list` command.

```
maprccli table replica list -path <path to the source table>
```

To verify that the `customers` table in the `newyork` cluster is a replica of the `customers` table in the `sanfrancisco` cluster, you could look at the output of this command:

```
maprccli table replica list -path /mapr/sanfrancisco/customers
```

5. Authorize replication between the tables by defining the source table as the upstream table for the replica by running the `maprccli table upstream add` command. Definition of the upstream table ensures that a table cannot replicate updates to any replica. Replication depends on a two-way agreement between the owners of the two tables.

```
maprccli table upstream add -path <path to the replica> -upstream <path
to the source table>
```

To add the `customers` table in the `sanfrancisco` cluster as an upstream source for the `customers` table in the `newyork` cluster:

```
maprccli table upstream add -path /mapr/newyork/customers -upstream /mapr/
sanfrancisco/customers
```

6. Verify that you specified the correct source table by running the `maprccli table upstream list` command.

```
maprccli table upstream list -path <path to the replica>
```

To verify this in our example scenario, you could use this command:

```
maprccli table upstream list -path /mapr/newyork/customers
```

7. If you set `-paused` to `true` when adding the replica, follow these steps:

- a) Load the replica with data from the source table by using the HPE Data Fabric Database CopyTable utility for binary tables or the [HPE Data Fabric Database JSON CopyTable](#) on page 7428 utility for JSON tables.
- b) Start replication with the command `maprccli table replica resume`. Here is the `maprccli` command:

```
maprccli table replica resume -path <path to the source
table> -replica <path to the replica>
```

For our example scenario, you could use this command:

```
maprccli table replica resume -path mapr/sanfrancisco/
customers -replica /mapr/newyork/customers
```

What to do next

- Be aware that changes to the structure of a source table are not replicated automatically to replicas. For more information, see [Adding a Column Family to a Replica](#) on page 1714
- You can check for alarms related to replication and whether synchronous replication is switched temporarily to asynchronous replication by looking in the Control System. See [Table-Replication Alarms](#).

Setting Up Multi-Master Replication Manually

You can run `maprccli` commands to set up multi-master replication, first establishing replication in one direction, and then establishing it in the other direction.

Prerequisites

- Verify that you have complete the steps to configure the clusters for table replication. For more information, see [Preparing Clusters for Table Replication](#) on page 1693.
- Run the `maprccli table info` command on the source table to verify that you have the following permissions:
 - `readperm`, which is required for reading from the table.
 - `replperm`, which is required for replicating from the table.
- Run the `maprccli table info` command on the destination table (if it already exists) to verify that you have the following permissions:
 - `bulkload`, which is required for the initial copy of source data into the destination table.
 - `replperm`, which is required for receiving replicated updates from the source table.

Procedure

1. For manual setup in one direction, follow these steps:

- a) Create the replica manually with the `maprcli table create` command. Use the `-copymetafrom` option to ensure that the metadata for the replica is identical to the metadata for the source table. Metadata includes column families, access control expressions (ACEs), and other attributes.

```
maprcli table create -path <path to the replica> -copymetafrom <path to the source table>
```

For example, to create the replica `customers` in the `newyork` cluster and use the metadata from the source table in the `sanfrancisco` cluster, you could use this command:

```
maprcli table create -path /mapr/newyork/customers -copymetafrom /mapr/sanfrancisco/customers
```

- b) Register the replica as a replica of the source table by running the `maprcli table replica add` command.

```
maprcli table replica add -path <path to the source table> -replica <path to the replica> -paused true
```

For example, to register the `customers` table in the `newyork` cluster as a replica of the `customers` table in the `sanfrancisco` cluster, you could use this command:

```
maprcli table replica add -path /mapr/sanfrancisco/customers -replica /mapr/newyork/customers -paused true
```

The `-paused` parameter ensures that replication does not start immediately after you register the source table as a source for this replica. You do this registration in step d.

- c) Verify that you specified the correct replica by running the `maprcli table replica list` command.

```
maprcli table replica list -path <path to the source table>
```

To verify that the `customers` table in the `newyork` cluster is a replica of the `customers` table in the `sanfrancisco` cluster, you could look at the output of this command:

```
maprcli table replica list -path /mapr/sanfrancisco/customers
```

- d) Authorize replication between the tables by registering the source table as the upstream table for the replica by running the `maprcli table upstream add` command. Definition of the upstream table ensures that a table cannot replicate updates to any replica. Replication depends on a two-way agreement between the owners of the two tables.

```
maprcli table upstream add -path <path to the replica> -upstream <path to the source table>
```

To add the `customers` table in the `sanfrancisco` cluster as an upstream source for the `customers` table in the `newyork` cluster:

```
maprcli table upstream add -path /mapr/newyork/customers -upstream /mapr/sanfrancisco/customers
```

- e) Verify that you specified the correct source table by running the `maprcli table upstream list` command.

```
maprcli table upstream list -path <path to the replica>
```

To verify this in our example scenario, you could use this command:

```
maprcli table upstream list -path /mapr/newyork/customers
```

- f) If you set `-paused` to `true` when adding the replica, follow these steps:
 1. Load the replica with data from the source table by using the HPE Data Fabric Database CopyTable utility for binary tables or the [HPE Data Fabric Database JSON CopyTable](#) on page 7428 utility for JSON tables.
 2. Start replication with the command `maprcli table replica resume`. Here is the `maprcli` command:

```
maprcli table replica resume -path <path to the source table> -replica <path to the replica>
```

For our example scenario, you could use this command:

```
maprcli table replica resume -path mapr/sanfrancisco/customers -replica /mapr/newyork/customers
```

2. For manual setup in the other direction, follow these steps:
 - a) Log into both the source and destination clusters.
 - b) Register the replica as a replica of the source table by running the `maprcli table replica add` command.

```
maprcli table replica add -path <path to the source table> -replica <path to the replica>
```

- c) Verify that you specified the correct replica by running the `maprcli table replica list` command.

```
maprcli table replica list -path <path to the source table>
```

- d) Authorize replication between the tables by defining the source table as the upstream table for the replica by running the `maprcli table upstream add` command. Definition of the upstream table ensures that a table cannot replicate updates to any replica. Replication depends on a two-way agreement between the owners of the two tables.

```
maprcli table upstream add -path <path to the replica> -upstream <path to the source table>
```

What to do next

- With multi-master replication, if one of the tables goes offline, direct client applications to the other table. For more information, see [Multi-Master Replication](#) on page 826.

- Be aware that changes to the structure of a source table are not replicated automatically to replicas. For more information, see [Adding a Column Family to a Replica](#) on page 1714
- You can check for alarms related to replication and whether synchronous replication is switched temporarily to asynchronous replication by looking in the Control System. See [Table-Replication Alarms](#).

Adding Table Replicas

Explains how to add table replicas using either the Control System, the CLI or the REST API.

About this task

You can register a HPE Data Fabric Database binary or JSON table as a replica of another HPE Data Fabric Database binary or JSON table using the Control System and the CLI. When you add a replica using the Control System, you can also setup and start replication between a source HPE Data Fabric Database Binary or JSON table to a replica HPE Data Fabric Database Binary or JSON table. Before you begin, complete the steps to [prepare HPE Data Fabric clusters for table replication](#).

Adding Table Replica Using the Control System

About this task

To replicate a table:

Procedure

1. Log in to the Control System and go to the **Replication** tab in the [table information page](#).
2. Click **Add Replica** and follow the steps for:
 - [Adding JSON Table Replicas](#) on page 1703
 - [Adding Binary Table Replicas](#) on page 1706
3. Click **Add Replica**.

Adding Table Replica Using the CLI or the REST API

About this task

To add a replica, run the following command:

```
/opt/mapr/bin/maprccli table replica add -path <table path> -replica
<replica table path>
```

To run this command, your user ID must have the following permissions:

- readAce and writeAce on both the source volume and the target volume
- lookupdir on directories in the paths of both tables
- readperm and replperm permissions on the source table

For complete reference information, see [table replica add](#) on page 2841.

NOTE: You also have the option to setup table replication with `maprccli table replica autoseup` which will setup and start replication. For more information, see [Setting Up Table Replication Using the CLI](#) on page 1696.

Adding JSON Table Replicas

Explains how to add replicas of JSON tables using either the Control System, the CLI or the REST API.

About this task

You can register a HPE Data Fabric Database JSON table as a replica of another HPE Data Fabric Database JSON table using either the Control System or the CLI. When you add a replica using the Control System, you can also setup and start replication between a source HPE Data Fabric Database JSON table to a replica HPE Data Fabric Database JSON table. Before you begin, complete the steps to [prepare HPE Data Fabric clusters for table replication](#).

Adding JSON Table Replica Using the Control System

About this task

To create a replica:

Procedure

1. Go to the table information page.
See [Viewing Table Information](#) on page 1630.
2. Click **Replicas** tab.
The list of replicas associated with the table displays.
3. Click **Add Replica**.
The **Add Replica** page displays.
4. Specify the following settings:

Destination Cluster	The destination cluster for the replica, where gateways are configured to allow source cluster to send updates.
Path to Replica	<p>The path to the replica.</p> <ul style="list-style-type: none"> • For a table on the local cluster, start the path at the volume mount point. For example, for a table named <code>testdst</code> under a volume with a mount point at <code>/volume1</code>, specify the following path: <code>/volume1/testdst</code> • For a table on another cluster, you must also specify the cluster name in the path. For example, for a table named <code>customerdst</code> under <code>volume1</code> in the <code>sanfrancisco</code> cluster, specify the following path: <code>/mapr/sanfrancisco/volume1/customerdst</code> <p> NOTE: For replication to a table, the command will fail if the replica path you specify points to table that already exists.</p>
Replication State	<p>Specify whether or not to start replication by choosing one of the following:</p> <ul style="list-style-type: none"> • Automatic Setup — Creates the table on the destination cluster, registers the table on the destination cluster as a replica, adds the current table as an upstream source, copies the content of the current table into the replica, and starts replication. • Pause Replication — Registers the table on the destination cluster as a replica and adds the current table as an upstream source, but prevents replication from immediately starting after. Pausing replica like this allows you to load the data into the replica from the current table, after which you can restart replication. <p> NOTE: Although visible, this option is not supported if the source or replica is on a remote secure cluster.</p>
Multi-Master Setup	<p>(Available only with Automatic Setup) Multi-master topology, in which there are two primary-secondary relationships, with each table playing both the primary and secondary roles. Client applications update both tables and each table replicates updates to the other.</p> <p>See Multi-Master Replication on page 826.</p>

If this is not selected, table replication will be basic primary-secondary topology. In this topology, you replicate one way from source tables to replicas. The replicas can be in a remote cluster or in the cluster where the source tables are located.

See [Primary-Secondary Replication](#) on page 821.

NOTE: Access control expressions on the replica that control permissions for updates to column families and columns are irrelevant because all updates from a source table arrive at a replica after having been authenticated at a gateway, which has the implicit authority to update replicas.

5. Set the following optional properties:

Throttle	Specify whether (Yes) or not (No) to throttle replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load.
Replicate Synchronously	Specify whether replication is synchronous (Yes) or asynchronous (No). See Modes of replication on page 821 for more information.
Encrypt On Wire	Specify whether (Yes) or not (No) to enable on-wire encryption. If you enable this, the local cluster and any other cluster that is part of the replication process must be enabled for security.
Compress On Wire	The type of on-wire compression. Choose one of the following: <ul style="list-style-type: none"> • Inherited • OFF • LZF • LZ4 • ZLib

6. Choose whether to:

- **Replicate Entire Document**
- **Replicate Selected Field Paths** — Specify the full path to the field in dotted notation. For example, suppose the table contained JSON documents that were of this general structure:

```
{
  "_id" : "ID",
  "a" : {
    "b" : {
      "c" : "value",
    },
    "e" : "value"
  }
}
```

To replicate field c, you must specify a.b.c as the field path. Do not use quotation marks and do not include spaces after each dot. Click:

- **Add Field** to add another field to replicate.

-  to remove a field.

By default, the entire document in the source table is replicated.

NOTE: If a field is added at a later date, replication for that field will start at that time.

7. Click **Add Replica**.

A table with the specified fields is created in the destination cluster, the new table is declared to be a replica of the source table, and the source table is registered as an upstream source for the replica.

Adding JSON Table Replica Using the CLI or the REST API

About this task

To add a replica, run the following command:

```
maprccli table replica add -path <table path> -replica <replica table path>
```

To run this command, your user ID must have the following permissions:

- readAce and writeAce on both the source volume and the target volume
- lookupdir on directories in the paths of both tables
- readperm and replperm permissions on the source table

For complete reference information, see [table replica add](#) on page 2841.

NOTE: You also have the option to use `maprccli table replica autosetup` which will setup and start replication. For more information, see [table replica autosetup](#) on page 2844.

Adding Binary Table Replicas

Explains how to add replicas of binary tables using either the Control System or the CLI.

About this task

You can register a HPE Data Fabric Database Binary table as a replica of another HPE Data Fabric Database Binary table using the Control System and CLI. When you add a replica using the Control System, you can also setup and start replication between a source HPE Data Fabric Database Binary table to a replica HPE Data Fabric Database Binary table. Before you begin, complete the steps to [prepare HPE Data Fabric clusters for table replication](#).

Adding Binary Table Replica Using the Control System

About this task

To create a replica:

Procedure

1. Go to the table information page.
See [Viewing Table Information](#) on page 1630.
2. Click **Replicas** tab.
The list of replicas associated with the table displays.
3. Click **Add Replica**.
The **Add Replica** page displays.

4. Specify the following settings:

Destination Cluster	The destination cluster for the replica, where gateways are configured to allow source cluster to send updates.
Path to Replica	<p>The path to the replica.</p> <ul style="list-style-type: none"> For a table on the local cluster, start the path at the volume mount point. For example, for a table named <code>testdst</code> under a volume with a mount point at <code>/volume1</code>, specify the following path: <code>/volume1/testdst</code> For a table on another cluster, you must also specify the cluster name in the path. For example, for a table named <code>customerdst</code> under <code>volume1</code> in the <code>sanfrancisco</code> cluster, specify the following path: <code>/mapr/sanfrancisco/volume1/customerdst</code> <p> NOTE: For replication to a table, the command will fail if the replica path you specify points to table that already exists.</p>
Replication State	<p>Specify whether or not to start replication by choosing one of the following:</p> <ul style="list-style-type: none"> Automatic Setup — Creates the table on the destination cluster, registers the table on the destination cluster as a replica, adds the current table as an upstream source, copies the content of the current table into the replica, and starts replication. Pause Replication — Creates the table on the destination cluster, registers the table on the destination cluster as a replica, adds the current table as an upstream source, but prevents replication from immediately starting after. Pausing replica like this allows you to load the data into the replica from the current table, after which you can restart replication. <p> NOTE: Although visible, this option is not supported if the source or replica is on a remote secure cluster.</p>
Multi-Master Setup	<p>(Available only with Automatic Setup) Multi-master topology, in which there are two primary-secondary relationships, with each table playing both primary and secondary roles. Client applications update both tables and each table replicates updates to the other.</p> <p>See Multi-Master Replication on page 826.</p> <p>If this is not selected, table replication will be basic primary-secondary topology. In this topology, you replicate one way from source tables to replicas. The replicas can be in a remote cluster or in the cluster where the source tables are located.</p> <p>See Primary-Secondary Replication on page 821.</p> <p> NOTE: Access control expressions on the replica that control permissions for updates to column families and columns are irrelevant because all updates from a source table arrive at a replica after having been authenticated at a gateway, which has the implicit authority to update replicas.</p>

5. Set the following optional properties:

Throttle	Specify whether (Yes) or not (No) to throttle replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load.
Replicate Synchronously	Specify whether replication is synchronous (Yes) or asynchronous (No). See Modes of replication on page 821 for more information.
Encrypt On Wire	Specify whether (Yes) or not (No) to enable on-wire encryption. If you enable this, the local cluster and any other cluster that is part of the replication process must be enabled for security.

Compress On Wire	<p>The type of on-wire compression. Choose one of the following:</p> <ul style="list-style-type: none"> • Inherited • OFF • LZF • LZ4 • ZLib
------------------	---

6. Choose whether to:

- **Replicate all column families**
- **Replicate Selected Column Families** — Specify the column family name and select:
 - **Include All Columns** — to replicate all the columns associated with the column family.
 - **Assign Columns** — to specify specific columns associated with the column family. To add more columns, click +.

By default, all columns in the source table are replicated.

NOTE: While the column families that you specify must already exist in the source table, the columns that you specify do not have to exist in the destination table for replication to succeed. If a column is added at a later date, replication for that column will start at that time.

7. Click **Add Replica**.

A table with the specified column families is created in the destination cluster, the new table is declared to be a replica of the source table, and the source table is registered as an upstream source for the replica.

Adding Binary Table Replica Using the CLI or the REST API

About this task

To add a replica, run the following command:

```
maprcli table replica add -path <table path> -replica <replica table path>
```

To run this command, your user ID must have the following permissions:

- readAce and writeAce on both the source volume and the target volume
- lookupdir on directories in the paths of both tables
- readperm and replperm permissions on the source table

For complete reference information, see [table replica add](#) on page 2841.

NOTE: You also have the option to use `maprcli table replica autoseup` which will setup and start replication. For more information, see [table replica autoseup](#) on page 2844.

Displaying the List of Table Replicas

Describes how to view information on the table replicas using the Control System or the CLI.

Displaying the List of Table Replicas Using the Control System

About this task

To view table replicas:

Procedure

1. Log in to the Control System and go to the [table information page](#).
2. Click **Replication**.

The page displays all the replicas and for each replica, the pane displays the following statistics:

Column Name	Column Description
Paused	Whether replication is paused.
Destination Cluster	The cluster on which the replica resides.
Destination Path	The path to the destination.
Status	<p>The status of the replica. Replicas can be in one of the following states:</p> <ul style="list-style-type: none"> • In-Synch — indicates replica is in synch with the source table and there are no more bytes to be sent from the source. • Pending — indicates replica is waiting for some bytes to be sent from the source. You can hover over the status to determine the number of bytes, puts, and buckets pending. • Broken — indicates there was an error during replication. If necessary, remove and re-create the replica.
Earliest	The epoch time in milliseconds of the oldest operation that is yet to be replicated to the replica.
Latest	The epoch time in milliseconds of the newest operation that is yet to be replicated to the replica.
Errors	Error () information, if any.
Compression Type	The type of on-wire compression.
Synchronous	Whether replication is synchronous or asynchronous.
Throttled	Whether replication is throttled.
Encrypted	Whether replication is encrypted.

Retrieving List of Table Replicas Using the CLI or the REST API

About this task

To view table replicas and associated replica statistics for a table, run the following command:

```
maprcli table replica list -path <table-path>
```

For more information, see [table replica list](#) on page 2853

Modifying Table Replica

Explains how to edit the properties of a replica using the Control System and the CLI.

Modifying a Table Replica Using the Control System

About this task

To modify the properties of a table replica:

Procedure

1. Go to the table information page.
See [Viewing Table Information](#) on page 1630.
2. Click **Replicas** to go to that tab.
3. Click  associated with the replica to modify.
The **Edit Replica** page displays.
4. Make changes to the following as desired:

Path to Replica	<p>The path to the replica.</p> <ul style="list-style-type: none"> • For a table on the local cluster, start the path at the volume mount point. For example, for a table named <code>testdst</code> under a volume with a mount point at <code>/volume1</code>, specify the following path: <code>/volume1/testdst</code> • For a table on another cluster, you must also specify the cluster name in the path. For example, for a table named <code>customerdst</code> under <code>volume1</code> in the <code>sanfrancisco</code> cluster, specify the following path: <code>/mapr/sanfrancisco/volume1/customerdst</code> <p> NOTE: For replication to a table, the command will fail if the replica path you specify points to a table that already exists.</p>
Replication State	<p>Specify whether or not to start replication by choosing one of the following:</p> <ul style="list-style-type: none"> • Automatic Setup — Creates the table on the destination cluster, registers the table on the destination cluster as a replica, adds the current table as an upstream source, copies the content of the current table into the replica, and start replication. • Pause Replication — Creates the table on the destination cluster, registers the table on the destination cluster as a replica, adds the current table as an upstream source, but prevents replication from immediately starting after. Pausing replica like this allows you to load the data into the replica from the current table, after which you can restart replication.
Multi-Master Setup	<p>(Available only with Automatic Setup) Multi-master topology, in which there are two primary-secondary relationships, with each table playing both primary and secondary roles. Client applications update both tables and each table replicates updates to the other.</p> <p>See Primary-Secondary Replication on page 821.</p> <p>If this is not selected, table replication will be basic primary-secondary topology, which is the default. In this topology, you replicate one way from source tables to replicas. The replicas can be in a remote cluster or in the cluster where the source tables are located.</p> <p>See Primary-Secondary Replication on page 821.</p> <p> NOTE: Access control expressions on the replica that control permissions for updates to column families and columns are irrelevant because all updates from a source table arrive at a replica after having been authenticated at a gateway, which has the implicit authority to update replicas.</p>

5. Set the following optional properties:

Throttle	Specify whether (Yes) or not (No) to throttle replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load.
Replicate Synchronously	Specify whether replication is synchronous (Yes) or asynchronous (No).
Encrypt On Wire	Specify whether (Yes) or not (No) to enable on-wire encryption. If you enable this, the local cluster and any other cluster that is part of the replication process must be enabled for security.
Compress On Wire	The type of on-wire compression. Choose one of the following: <ul style="list-style-type: none"> • Inherited • OFF • LZF • LZ4 • ZLib

6. Choose whether to:

- For JSON table replica:
 - **Replicate Entire Document**
 - **Replicate Selected Field Paths** — Specify the full path to the field in dotted notation. For example, suppose the table contained JSON documents that were of this general structure:

```
{
  "_id" : "ID",
  "a" : {
    "b" : {
      "c" : "value",
      "e" : "value"
    }
  }
}
```

To replicate field c, you must specify a.b.c as the field path. Do not use quotation marks and do not include spaces after each dot. Click:

- **Add Field** to add another field to replicate.
-  to remove a field.
- For Binary table replica:
 - **Replicate All Column Families**
 - **Replicate Selected Column Families** — Specify the column family name and select:
 - **Include All Columns** — to replicate all columns associated with the column family.
 - **Assign Columns** — to specify specific columns associated with the column family. To add more columns, click +.

- Click **Edit Replica** for the changes to take effect.

Modifying a Table Replica Using the CLI or REST API

About this task

The basic command to modify a table replica is:

```
maprcli table replica edit -path <table path> -replica <replica table path>
```

To run this command, your user ID must have the following permissions:

- readAce and writeAce on both the source volume and the target volume
- lookupdir on directories in the paths of both tables
- readperm and replperm permissions on the source table

For complete reference, see [table replica edit](#) on page 2849.

Removing Table Replicas

Explains how to un-register one or more replicas using either the Control System or the CLI.

Removing Replication Using the Control System

About this task

Procedure

- Go to the table information page.
See [Viewing Table Information](#) on page 1630.
- Click **Replication** to go to that tab.
- Select the replicas to remove by clicking the associated checkbox.
Selecting the checkbox next to a replica makes the **Actions** drop-down menu available.
- Select **Remove Replica(s)** from the **Actions** drop-down menu.
The **Remove Replica(s)** confirmation window displays.
- Verify the list of replicas to remove and click **Remove Replica**.
If necessary, click  to remove a replica.

The selected replicas are no longer replicas of the source table and will no longer receive updates from the source table. You must also remove upstream source to remove the association between the source table and the replica table. For more information, see [Removing Upstream Sources](#).

Removing Replication Using the CLI or REST API

About this task

The un-register a replica, run the following command:

```
maprcli table replica remove -path <table path> -replica <replica table path>
```

To run this command, your user ID must have the following permissions:

- readAce and writeAce on both the source volume and the target volume

- `lookupdir` on directories in the paths of both tables
- `readperm` and `replperm` permissions on the source table

For complete reference, see [table replica remove](#) on page 2857.

Pausing Table Replication

Explains how to pause table replication of data from a source HPE Data Fabric Database binary or JSON table to a replica HPE Data Fabric Database binary or JSON table respectively using either the Control System or the CLI.

Pausing Table Replication Using the Control System

About this task

Procedure

1. Go to the table information page.
See [Viewing Table Information](#) on page 1630.
2. Click **Replicas** to go to that tab.
3. Select the replicas to pause by clicking the associated checkbox.
Selecting the checkbox next to a replica makes the **Actions** drop-down menu available.
4. Select **Pause Replication** from the **Actions** drop-down menu.
The **Pause Replication** confirmation window displays.
5. Verify the list of replicas to pause and click **Pause Replication** to pause replication on the selected replicas.
If necessary, click  to remove a replica from being paused.

Pausing Table Replication Using the CLI or REST API

About this task

The pause replication, run the following command:

```
maprcli table replica pause -path <table path> -replica <replica table path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables
- `readperm` and `replperm` permissions on the source table

For complete reference, see [table replica pause](#) on page 2856.

Resuming Table Replication

Explains how to resume replication between a source HPE Data Fabric Database binary or JSON table and a replica of that table when the replication state is set to paused from the Control System or by the `maprcli table replica add` or the `maprcli table replica pause` command.

Resuming Replication Using the Control System

About this task

Procedure

1. Go to the table information page.
See [Viewing Table Information](#) on page 1630.
2. Click **Replicas** to go to that tab.
3. Select the replicas in paused state by clicking the associated checkbox.
Selecting the checkbox next to a replica makes the **Actions** drop-down menu available.
4. Select **Resume Replication** from the **Actions** drop-down menu.
The **Resume Replication** confirmation window displays.
5. Verify the list of replicas for which to resume replication and click **Resume Replication**.
If necessary, click  to leave the replica in paused state.

Resuming Replication Using the CLI or REST API**About this task**

The resume replication, run the following command:

```
maprcli table replica resume -path <table path> -replica <replica table path>
```

To run this command, your user ID must have the following permissions:

- readAce and writeAce on both the source volume and the target volume
- lookupdir on directories in the paths of both tables
- readperm and replperm permissions on the source table

For complete reference, see [table replica resume](#) on page 2859.

Adding a Column Family to a Replica

Changes to the structure of a source table are not automatically replicated to replica table. You must complete the following steps to add a column family to a replica.

About this task

When an entire table is being replicated, new column families are not automatically created at the replica. However, once you add the new column family to the replica then updates to the new column family will immediately start being replicated.

When you are replicating a subset of column families and columns, you must add the new column family to the replica and also run the copytable utility to initially populate the new column family in the replica table.

Procedure

1. Pause replication by running the [maprcli table replica pause](#) command.
2. Add the new column family to the replica by running the [maprcli table replica edit](#) command.
3. If the replica includes a subset of column families and columns from the source table, copy the data from the new column family from the source table into the replica by using the CopyTable utility. Use the `-columns` parameter to specify the name of the column family.

- Resume replication by running the `maprccli table replica resume` command.

Viewing Active Table Replication Alarms

Describes how to view active table replication alarms using the Control System and the CLI.

About this task

You can view table replication alarms using the Control System, the log files, and the CLI.

Viewing Active Table Alarms in the Control System

Procedure

- Log in to the Control System and click **Data > Tables** to view table replication alarms in the **Active Alarms** pane.

You can:

- [View](#) information related to the alarm.
- [Dismiss](#) an alarm.
- [Mute](#) an alarm.

See [Table-Replication Alarms](#) on page 3411 for more information on the table alarms.

Retrieving Active Table Replication Alarms Using the CLI or REST API

About this task

Alarms for replication are issued per volume rather than per source table. To retrieve table replication alarms, run the following command:

```
maprccli alarm list -cluster <cluster name> -type volume
```

For complete reference information, see [alarm list](#) on page 2298.

Viewing Table Replication Alarms in the Log Files

About this task

The log files `mfs.log-5` and `cldb.log` display these alarms. These files are located in the `/opt/mapr/logs` directory.

Managing Upstream Source for Table Replicas

You can set up a table to be the upstream source for replicas. This is especially useful if you did not set up replication automatically when setting up replicas.

Setting Table as Upstream Source for a Replica

Explains how to set up the current table as the upstream source for a replica if the replica was not configured to automatically re-sync with the current table.

Setting Up Current Table as Upstream Source for a Replica Using the Control System

About this task

To set up a table as the upstream source for replicas:

Procedure

- Go to the **Replication** tab in the [table information page](#).

2. Select the checkbox beside the replicas that do not have the current table configured as upstream source for automatic re-sync.
Selecting a checkbox next to a replica makes the **Actions** drop-down menu available.
3. Select **Set Current Table as Upstream Source** from the **Actions** drop-down menu.
The **Set Current Table as Upstream Source** dialog displays.
4. Review the list of selected replicas and click **Set Upstream Source**.
The current table will automatically send updates to the replica(s).

Setting Up Table as Upstream Source for a Replica Using the CLI or REST API

About this task

The basic command to set a table as the upstream source for a replica is:

```
maprcli table upstream add -path <replica table path> -upstream <source table path>
```

See [table upstream add](#) on page 2863 for complete reference information.

Adding Upstream Source for Table

Describes how to add an upstream source for a table using either the Control System or the CLI.

Adding Upstream Source Using the Control System

About this task

To add an upstream source for the current table:

Procedure

1. Log in to the Control System and go to the **Replication** tab in the [table information page](#).
2. Click **Add Upstream Source Table** in the **Upstream Sources** pane.
The **Add Upstream Source Table** window displays.
3. Enter the path to the upstream source table.
 - For a path on the local cluster, start the path at the volume mount point. For example, for a table named testsrc under volume1 which has a mount point at /volume1, specify the following path: /volume1/testsrc
 - For a path on another cluster, you must also specify the cluster name in the path. For example, for a table named customersrc under volume1 in the sanfrancisco cluster, specify the following path: /mapr/sanfrancisco/volume1/customersrc
4. Click **Add Upstream Source Table**.

Adding Upstream Source Using the CLI or the REST API

About this task

The basic command to add upstream source is:

```
maprcli table upstream add -path <table path> -upstream <upstream table path>
```

See [table upstream add](#) on page 2863 for complete reference information.

Listing all Upstream Sources for a Table

Explains how to retrieve and view the list of upstream sources for a table using either the Control System, or the CLI.

Viewing Upstream Sources Using the Control System

About this task

To view the list of upstream sources:

Procedure

- Log in to the Control System and go to the **Replication** tab in the [table information page](#).
The list of upstream sources for the table displays in the **Upstream Source** pane. For each upstream source, the pane displays the following:

Column Name	Column Description
IDX	The index number of the replica table.
Upstream Source Cluster	The cluster on which the upstream table resides.
Upstream Source Path	The path to the upstream source table.
UUID	The replica table's universally unique identifier.

Selecting the checkbox beside an upstream source makes the **Remove Upstream Source(s)** button available. You can:

- [Add](#) an upstream source table
- [Remove](#) an upstream source table

Retrieving Upstream Sources Using the CLI or the REST API

About this task

The basic command to retrieving the list of upstream sources for a table is:

```
maprcli table upstream list -path <table path>
```

See [table upstream list](#) on page 2865 for complete reference information.

Removing Upstream Source

Explains how to remove a table as an upstream source using either the Control System or the CLI.

Removing Upstream Source Using the Control System

About this task

To remove upstream source:

Procedure

- Log in to the Control System and go to the **Replication** tab in the table information page.
See [Viewing Table Information](#) on page 1630.
- Select the upstream sources to remove in the **Upstream Source** pane by clicking the associated checkbox.
- Click **Remove Upstream Source Table** in the **Upstream Source** pane.
The **Remove Upstream Source Table** confirmation dialog displays.
- Verify the list of upstream sources to remove and click **Remove Upstream Source Table**.

*Removing Upstream Source Using the CLI or the REST API***About this task**

The basic command to remove upstream source is:

```
maprcli table upstream remove -path <table path> -upstream <upstream table path>
```

See [table upstream remove](#) on page 2866 for complete reference information.

Addressing High Memory File Server Alarm for JSON Table Replication

The topic describes the troubleshooting steps for memory overflow issues with JSON tables where replication has been set up, secondary indexes have been created on the JSON table being replicated, and table row size less than 1 KB.

About this task

When you are working with JSON tables and High File Server Memory alarm is raised during table replication that has been set up between the JSON tables, check if secondary indexes are created on the destination table and the table row size is smaller than 1 KB.

If all the aforementioned conditions are met, follow the steps given below to resolve the memory overflow issue.

Procedure

1. Check the table region size to identify tables with memory overflow by running the [table region list](#) on page 2833 command.
2. Use the [table region split](#) on page 2839 command to manually split destination table regions with memory overflow or high memory usage. Split until each table region size is equal to or lower than 512 MB. This is a remedial measure for the memory overflow problem.
3. Run the [table edit](#) on page 2808 command and reset the regionsizemb parameter on the destination table to 512 MB from the default 4 GB value. This is a preventive measure that helps with avoiding the Data Fabric file system from running out of memory during replication of JSON tables, where row size smaller than 1 KB and a secondary index has been created on the JSON table.

Managing Secondary Indexes

Describes how to manage secondary indexes, including adding, deleting, and listing indexes, setting up your cluster for querying, and troubleshooting index usage.

You can add and manage secondary indexes using either the `maprcli table index` commands or the Control System. The `maprcli table index` commands are also available using the REST API. The following diagram provides links to information about managing indexes.

1. Describes the tasks needed to prepare your environment so you can query HPE Data Fabric Database JSON tables using secondary indexes.
2. Describes how to add secondary indexes on HPE Data Fabric Database JSON tables.
3. Describes how to view information about secondary indexes. This includes information about whether an index is lagging its parent JSON table.
4. Describes how to use the HPE Data Fabric Database shell to examine the contents of a secondary index. This includes displaying information about errors encountered inserting into the index.
5. Describes how to verify that the data in a secondary index is consistent with its JSON table.
6. This topic describes how to remove secondary indexes that are no longer needed.
7. Describes how to debug and troubleshoot usage of secondary indexes.

The following permissions are required to add, remove, and list indexes. Indexes share the same volume and topology as its JSON table, so the applicable permissions are on the volume and JSON table path.

- readAce on the volume
- lookupdir on directories in the table path

NOTE: The mapr user is not treated as a superuser. HPE Data Fabric Database does not allow the mapr user to perform this operation unless that user is given the relevant permission or permissions with access-control expressions.

Also, to add or remove an index, the user must be the creator of the table or a user with indexperm permission.

Preparing Clusters for Querying using Secondary Indexes on JSON Tables

Describes the tasks needed to prepare your environment so you can query HPE Data Fabric Database JSON tables using secondary indexes.

Installing with the Data Fabric Installer

To install Data Fabric using the Data Fabric installer, follow the steps outlined at [Installing with the Installer](#) on page 327.

Starting with release 6.0.1, you do not have to enable a separate query service to use secondary indexes. The **Operational Applications with HPE Data Fabric Database** template installs and configures the replication gateways needed to update secondary indexes in HPE Data Fabric Database JSON and includes the components needed to run OJAI queries.

You must enable the [OJAI Distributed Query Service](#) on page 711 to use certain features. The following table summarizes the differences in the functionality of OJAI queries when you do and do not have the service enabled:

Service Not Enabled	Service Enabled
<ul style="list-style-type: none"> • Can run queries that use a single secondary index • Can sort data in your queries up to a configurable limit 	<ul style="list-style-type: none"> • Can run queries that use multiple secondary indexes • Can sort data in your queries without any limit • Can run queries in parallel

Selecting any of the following templates enables the OJAI Distributed Query Service:

- **Operational Applications with HPE Data Fabric Database and Distributed Query Service**

- **Data Fabric Cluster: Batch, interactive and real-time analytics**
- **Analytics with HPE Data Fabric Database**

You can also explicitly enable the OJAI Distributed Query Service by selecting the service in the **Custom Services** template.

For more information about installer templates, see [Auto-Provisioning Templates](#) on page 7568.

For more information about how secondary index selection and execution works in HPE Data Fabric Database JSON, see [Selection and Execution of Secondary Indexes](#) on page 792.

NOTE: The **OJAI Query Service** has been renamed to the **OJAI Distributed Query Service** in release 6.0.1. All information about the OJAI Distributed Query Service applies to the OJAI Query Service, except where noted.

Installing without the Data Fabric Installer

Other sections of the documentation describe the detailed steps for installing and configuring without the Data Fabric installer. Generally, you need to perform the following steps:

1. Install software.

To install Data Fabric without using the Data Fabric installer, follow the steps outlined at [Installing without the Installer](#) on page 229. In addition to installing Data Fabric core packages, you also need to [install Drill](#) if you want advanced secondary index selection, sorts on large data sets, and parallel query execution. When installing Drill, make sure to [Configure the OJAI Distributed Query Service](#) on page 293.

2. Install and configure replication gateways.

Updates are propagated from the JSON tables using the [Gateways for Replicating HPE Data Fabric Database Tables](#) on page 831. You need to install the replication gateways. Since the source JSON table and the secondary index are on the same volume within a cluster, configure an [intracluster gateway](#). In this type of gateway, the source and destination clusters are the same.

If your gateways are running on the same nodes as CLDB, then no additional configuration steps are required. See [Configuring Gateways for Table and Stream Replication](#) on page 1789 for details about this scenario and other options for configuring your gateways.

Upgrades

Other sections of the documentation describe the detailed steps for upgrades. Generally, you need to perform the following steps:

1. Upgrade your Data Fabric software by following the instructions at [Upgrading a Manually Installed Fabric](#) on page 452.
2. [Install Drill](#), if you have not already done so and want to sort large data sets and run queries in parallel.
3. When installing Drill, make sure to [Configure the OJAI Distributed Query Service](#) on page 293.
4. If you are upgrading without the Data Fabric installer, follow step 2 in the previous section to install and configure replication gateways.
5. Enable the replication support needed to propagate index updates by running the following command:

```
maprcli cluster feature enable -name mfs.feature.db.streams.v6.support
```

See [Step 4: Enable New Features](#) on page 492 for further details.

IMPORTANT: If you are using a [Manual Rolling Upgrade Description](#) on page 479, you must upgrade all nodes running replication gateways before performing updates on tables with indexes. Otherwise, the index updates will hang.

Adding Secondary Indexes on JSON Tables

Describes how to add secondary indexes on HPE Data Fabric Database JSON tables.

About this task

You can add secondary indexes using the Control System, or the `maprc li table index` commands.

If you are adding an index on a large table, particularly if it contains complex data, you should consider modifying the `mfs.db.parallel.copyregions` parameter using the `maprc li config save` command. The parameter controls the degree of parallel processing in your HPE Data Fabric cluster. Increasing parallelism can improve the index build time by optimizing the build's intermediate copy operation.

Permissions

You need the following permissions to add an index:

- `readAce` on the volume
- `lookupdir` on directories in the table path
- `indexperm` permission on the table

If you created the table in version 6.0 or later, you automatically have `indexperm` permission. For tables created before 6.0, even if you are the owner of the table, you must explicitly add `indexperm` permission.

NOTE: The `mapr` user is not treated as a superuser. HPE Data Fabric Database does not allow the `mapr` user to perform this operation unless that user is given the relevant permission or permissions with access-control expressions.

See [Restrictions on Secondary Indexes](#) on page 775 for information about other restrictions.

NOTE: If you are configuring secondary index on a JSON table that has replication set up and the JSON table has row size of less than 1 KB, run the `table edit` command to reset the `regionsizeMB` parameter to 512 MB from the default 4 GB value. This prevents a memory overflow during the table replication operation.

Adding Indexes Using the Control System

Procedure

1. Log in to the Control System and go to the **Indexes** tab in the [table information page](#).
2. Click **Add Index** to display the **Add Index** page.
3. Specify the following settings:
 - a) Specify the name of the index in the **Index Name** field.
 - b) Specify whether (**Yes**) or not (**No**) the index is hashed in the **Hashed** field. If **Yes**, specify the number of hash index partitions for distributing the keys.
See [Hashed Indexes](#) on page 765 for information about whether you should create a hashed index.
4. Specify the list of indexed fields under **FIELDS INDEXED**.
 - a) Specify the name of the indexed field in the **Field Name** text field.

- b) Select the ordering (**Ascending** or **Descending**) for the field from the **Order** drop-down menu.
 - c) Select the function of the field from the **Function** drop-down menu.
- Before defining an index that specifies index keys with CAST functions, see [Using Casts in Secondary Indexes](#) on page 767 for more information on creating indexes using CAST functions.

TIP: To add more indexed fields, click **Add Another** and repeat step 4.

5. Specify the names of the included fields under **INCLUDED FIELDS**.

For more information, see [Covering Indexes](#) on page 770.

TIP: To add additional included fields, click **Add Another** and repeat step 5.

6. Click **Add Index** to create the index.

Adding Indexes Using the CLI

About this task

The following is the basic command for adding a secondary index on a JSON table.

```
maprccli table index add
-path <path>
-index <index name>
-indexedfields < indexed field names >
```

See [table index add](#) on page 2813 for a description of the complete syntax.

Troubleshooting Secondary Indexes

Describes how to debug and troubleshoot usage of secondary indexes.

The following table lists problems you may encounter when using secondary indexes. Based on the symptoms listed in the first column, refer to the section in the third column to further troubleshoot the issue.

Symptom	Possible Cause	Troubleshooting Steps
Query performance is slow	Query is not using secondary indexes	<ol style="list-style-type: none"> Determining the Query Execution Path for OJAI Queries on page 1727 Determining Secondary Index Usage on page 1728
	Non-optimal OJAI query plan chosen	Examining the OJAI Query Plan on page 1728
	Non-optimal query plan chosen by OJAI Distributed Query Service	Determining Index Use on page 4879
Inconsistent query results	Secondary index update lag	Identifying Secondary Index Lag on page 1729
	Unresolved encoding errors	Troubleshooting Secondary Index Encoding Errors on page 1731
Query runs out of memory	Memory configuration in the OJAI Distributed Query Service set too low	Adjusting Memory Settings in the OJAI Distributed Query Service on page 1732

Symptom	Possible Cause	Troubleshooting Steps
High File Server Memory alarm is raised when JSON table replication operation runs out of memory, if secondary index has been created on the table.	The table row size less than 1 KB causes memory leak.	Addressing High Memory File Server Alarm for JSON Table Replication on page 1718

Secondary Index Restrictions

When troubleshooting secondary indexes, you should also keep in mind the following restrictions:

Name Restrictions

You cannot use the following characters in the index name and in the indexed fields:

```
< > ? % \
```

To use the following characters in the index name and in the indexed fields, enclose them either in single or double quotes:

```
; | ( ) /
```

For example:

```
maprccli table index
add -path /volume1/MYTABLE -index
"MYTABLE1_ANALYSIS_1 ^=#;{}&()/" \
-indexedfields "_timestamp":desc, "
", "LOTNo" -includedfields \
" ", "^=#;{}&()/" (or)

maprccli table index
add -path /volume1/MYTABLE -index
'MYTABLE1_ANALYSIS_1 ^=#;{}&()/' \
-indexedfields "_timestamp":desc, "
", "LOTNo" -includedfields \
' ', '^=#;{}&()/'
```

To use either the ' or the " character in the index name and in the indexed fields, enclose:

- the ' character within double quotes (")
- the " character within single quote (')

For example:

```
maprccli table index
add -path /volume1/MYTABLE -index
"MYTABLE1_ANALYSIS_1 ^=#;{}&()/" \
-indexedfields "_timestamp":desc, "
", "LOTNo" -includedfields \
" ", "^=#;{}&()/" (or)

maprccli table index
add -path /volume1/MYTABLE -index
'MYTABLE1_ANALYSIS_1 ^=#;{}&()/' \
-indexedfields "'_timestamp":desc, "
", "LOTNo" -includedfields \
' ', '^=#;{}&()/'
```

Type Restrictions

- If a composite index includes the same subfield in multiple indexed fields, the implied types of the subfields must be consistent.

For example, you cannot create an index with the following indexed fields:

```
a.b[].c, a.b.d
```

Although subfield b appears in both indexed fields, in the first, it is an array and in the second, it is a nested document.

See [Composite Indexes and Container Field Paths](#) on page 764 for more details.

Size Restrictions

- The maximum size of all indexed fields in an index is 32 KB.

If the collective size exceeds 32 KB, then an insert of the corresponding document results in an encoding error (INDEX_ROW_KEY_ENCODER_ERROR_ENCODING_IS_TOO_LONG).

- The maximum number of indexes that you can create on a JSON table is 32.

Field Definition Restrictions

- You cannot specify individual array elements as indexed fields.
- You cannot specify a table's `_id` field as an indexed field.
- If a field contains an array of nested documents and you want to index on subfields in the nested documents, then you must define the indexed field using a container field path.
- You can include a specific field only once as either an indexed or included field, with the following two exceptions:
 - The indexed field is a container field path:

```
maprccli table index add -path /
people \
  -index phoneNumberIdx \
  -indexedfields
Phones[].Number \
  -includedfields
Phones[].Number
```

- The field specifies a cast to another type.

You can create an index in which the score field is an indexed field cast as a double type, and score is also an included field. The included field retains the original data type of the score field:

```
maprcli table index add -path /
castTable \
  -index castIdx1 \
  -indexedfields
'$CAST(score@DOUBLE)' \
  -includedFields score
```

You can create an index in which the score field is an indexed field, cast as a double type, and the score field is also another indexed field, cast as a long type:

```
maprcli table index add -path /
castTable \
  -index castIdx2 \
  -indexedfields
'$CAST(score@DOUBLE)', '$CAST(score@LONG)'
```

- You cannot use casts with included fields.
- You cannot specify a field as either an indexed or included field if the field is also specified as a column family JSON path name.

For example, suppose you have the following JSON table:

```
{
  "_id" : "ID",
  "a" : {
    "b" : {
      "c" :
"value",
      "d" :
"value"
    },
    "e" : "value"
  }
}
```

If you create a column family at field c in the JSON path a.b.c, you cannot define field a.b.c as either an indexed or included field. You can define the fields a, a.b, and a.b.d as either indexed or included fields.

- You cannot specify an included field in which the data in the field spans more than one column family.

In the following example, the included field `sl1.sl2` spans column families, `cf2` and `cf3`:

```
maprcli table cf list -path /cftab
compressionperm readperm
traverseperm jsonfamilypath
writeperm minversions
maxversions compression
ttl          inmemory cfname
memoryperm
u:root          u:root
u:root
u:root          0
1                lz4
2147483647 false      default
u:root
u:root          u:root
u:root          sl1
u:root          0
1                lz4
2147483647 false      cf1
u:root
u:root          u:root
u:root          sl1.sl2.sl3
u:root          0
1                lz4
2147483647 false      cf2
u:root
u:root          u:root
u:root          sl1.sl2.sl3.sl4
u:root          0
1                lz4
2147483647 false      cf3
u:root

maprcli table index add -path /
cftab -index i1 -indexedfields
sl1.sl2.sl3.sl4.l4a,
sl1.l1a -includedfields
sl1.sl2,sl1.sl2.sl3.sl4.sl5.l5b -js
on
{
    "timestamp":1507419777919,
    "timeofday":"2017-10-07
04:42:57.919 GMT-0700 PM",
    "status":"ERROR",
    "errors":[
        {
            "id":22,

"desc":"Data for included field
sl1.sl2 may not span more than one
column family."
        }
    ]
}
```

- You cannot specify a composite index with more than one container field path as your indexed fields, unless the prefixes of the container field paths are the same.

See [Composite Indexes and Container Field Paths](#) on page 764 for more details.

- You cannot specify a composite index with an indexed field that is a subfield of another indexed field.

For example, you cannot create an index with the following indexed fields:

```
a, a.b
```

The indexed field `a.b` is a subfield of the indexed field `a`.

Option Restrictions

- As indexes are automatically split, you cannot disable splits when you create your index.

Index Use Restrictions

- Indexes do not optimize non-existence filter conditions.

[table index list](#) on page 2821

This topic describes how to list information about the secondary indexes created on HPE Data Fabric Database JSON tables.

[HPE Data Fabric Database JSON verifyindex](#) on page 7440

Describes how to use the HPE Data Fabric Database JSON `verifyindex` command to verify that the data in a secondary index is consistent with its JSON table.

[dbshell indexscan](#) on page 7414

Determining the Query Execution Path for OJAI Queries

You can determine whether an OJAI query directly accesses HPE Data Fabric Database JSON or leverages the OJAI Distributed Query Service by enabling Java OJAI tracing. Java OJAI tracing logs information that enables you to determine which execution path your queries use.

Follow the instructions at [Enable OJAI Tracing](#) on page 3856 to output tracing messages that include query plans.

If the query does not use the OJAI Distributed Query Service, you will see tracing like the following:

```
2017-07-17 17:35:59 TRACE OjaiDocumentStore:132 -
Query Plan: '[{"streamName":"DBDocumentStream","parameters":
{"queryConditionPath":false,"indexName":"abc_idx","projectionPath":
["c","b","a"],"primaryTable":"/tmp/test-728918932/ei_suffix_sort"}}]'
```

If a query uses the OJAI Distributed Query Service, you will see tracing like the following instead:

```
2017-07-17 18:51:13 TRACE OjaiDocumentStore:132 - Query
Plan: '[{"streamName":"DrillDocumentStream","parameters":{"sql":"select t.`$
$ENC00NQYF6YJUL5UW45AAL5UWI`,t.`$$document` from dfs.`/tmp/testTable` t
where (t.`l0_a4_int` = -92) order by t.`l0_a4_int` ASC,t.`_id` DESC"}}]'
```

```
2017-07-17 18:51:14 DEBUG DrillDocumentStream:120 -
DocumentResultsListener[1].queryIdArrived(queryId =
```

```
2692966d-0888-96e2-fa09-0d9befcd3173 ,sql string = select t.`$
$ENC00NQYF6YJUL5UW45AAL5UWI`,t.`$$document` from dfs.`/tmp/testTable` t
where (t.`l0_a4_int` = -92) order by t.`l0_a4_int` ASC,t.`_id` DESC)
```

Note that the **Query Plan** in the second trace fragment above contains a **DrillDocumentStream** instead of a **DBDocumentStream**. The **sql** parameter in that stream shows a SQL query. This is also missing in the first trace fragment above. The presence of the SQL query indicates that OJAI passes the query to the OJAI Distributed Query Service, as noted in the third trace fragment.

For further information about OJAI query plans, see [Examining the OJAI Query Plan](#) on page 1728. For background information about different query execution paths, see [OJAI Distributed Query Service](#) on page 711.

Determining Secondary Index Usage

This section describes how to determine whether a query is using secondary indexes, depending on the query execution path used.

Determine whether your query uses the OJAI Distributed Query Service by following the steps outlined at [Determining the Query Execution Path for OJAI Queries](#) on page 1727. The following sections describe next steps depending on the execution path.

Simple OJAI Queries

Using the tracing described at [Determining the Query Execution Path for OJAI Queries](#) on page 1727, you will see the following in the log output:

```
2017-07-17 17:35:59 TRACE MapRDBTableImplHelper:703 - Scan on Index:
'testIndex', Primary Table is: '/tmp/testTable', Index Scan QueryCondition:
'((field < {"$numberLong":101}))',
Index Scan startRow: '\x0FZ', Index Scan stopRow: '\x0F\x89\xCA\x80\x00'
```

The "**Scan on Index**", highlighted in bold, indicates OJAI used a secondary index to process the query.

Queries Requiring the OJAI Distributed Query Service

The tracing output described at [Determining the Query Execution Path for OJAI Queries](#) on page 1727 contains a **queryId**, highlighted in bold:

```
2017-07-17 18:51:14 DEBUG DrillDocumentStream:120 -
DocumentResultsListener[1].queryIdArrived(queryId =
2692966d-0888-96e2-fa09-0d9befcd3173 ,
sql string = select t.`$ENC00NQYF6YJUL5UW45AAL5UWI`,t.`$$document` from
dfs.`/tmp/testTable` t where (t.`l0_a4_int` = -92) order by t.`l0_a4_int`
ASC,t.`_id` DESC)
```

Use this **queryId** to retrieve more information through the Drill Web Console, including the query plan selected by the OJAI Distributed Query Service. See [Query Profile](#) on page 4880 for details.

Examining the OJAI Query Plan

This section describes two ways to access a Java OJAI query plan and provides general information about how to interpret the query plan. You can examine the query plan to determine if the Java OJAI client chooses an appropriate execution path.

Using OJAI Tracing

After following the steps at [Determining the Query Execution Path for OJAI Queries](#) on page 1727, if you determine that your query directly accesses HPE Data Fabric Database JSON and does not use the OJAI Distributed Query Service, you can further examine the query plan in the trace output.

As noted in the referenced topic, to enable tracing, set the following property in your `log4j.properties` file, located in the `/opt/mapr/conf` directory:

```
log4j.logger.com.mapr.ojai.store.impl=TRACE, stdout
```

In the following logged output, the query plan uses an index named `i1_idx` and projects field `id1`. It also limits the result to two documents:

```
2017-10-18 11:29:32,876 TRACE
[main] com.mapr.ojai.store.impl.OjaiDocumentStore -
Query Plan: '[{"streamName":"DBDocumentStream","parameters":
{"queryConditionPath":false,"indexName":"i1_idx","projectionPath":
["id1"],"primaryTable":"/tmp/test-728918932/tab"}},
{"streamName":"LimitStream","parameters":{"limit":2}}]'
```

Calling `QueryResult.getQueryPlan`

Instead of using OJAI tracing, you can programmatically retrieve query plans by calling [QueryResult.getQueryPlan](#). The method returns a JSON document that is a list of Maps. Each Map in the list represents a DocumentStream in the query plan, which corresponds to an operation. The order of the list represents the order the HPE Data Fabric Database client processes each operation. Each Map entry contains the name of the DocumentStream (`streamName`) and its parameters. You may see Map entries corresponding to the following DocumentStreams in a query plan:

- `DBDocumentStream` - Accesses HPE Data Fabric Database without the OJAI Distributed Query Service
- `DrillDocumentStream` - Uses the OJAI Distributed Query Service to process the query
- `LimitStream` - Limits the number of documents to return
- `OffsetStream` - Skips past specified number of documents before reading

IMPORTANT: The DocumentStream names and their parameters are subject to change from one release to the next. Take that into consideration if you plan to write tools that interpret the contents of an OJAI query plan

Identifying Secondary Index Lag

This section describes the commands you use to determine if updates to a secondary index are lagging.

Secondary index lag can occur due to [asynchronous secondary index updates](#). Use [maprcli table index list](#) and [mapr verifyindex](#) to assess if there is update lag in an index and to see details on the updates that are lagging.

Run `maprcli table index list`

The `maprcli table index list` command lists information about indexes created on a table. To retrieve the most current status, specify the optional `refreshnow` parameter. Examine the values of the following fields to determine if an index is lagging:

- `isUptodate` - True if the index is up-to-date
- `bytesPending` - The number of bytes pending propagation to the index
- `putsPending` - The number of puts pending propagation to the index
- `minPendingTS` - The timestamp of the oldest put pending propagation to the index
- `maxPendingTS` - The timestamp of the most recent put pending propagation to the index

In the sample output below, the index is up-to-date.

```
maprcli table index list -path /demo/business -json
{
  "timestamp":1506617667735,
  "timeofday":"2017-09-28 04:54:27.735 GMT+0000 PM",
  "status":"OK",
  "total":1,
  "data":[
    {
      "cluster":"my.cluster.com",
      "type":"maprdb.si",
      "indexFid":"2049.93.10257820",
      "indexName":"i1",
      "hashed":false,
      "indexState":"REPLICA_STATE_REPLICATING",
      "idx":1,
      "indexedFields":"a.b:ASC",
      "isUptodate":true,
      "minPendingTS":0,
      "maxPendingTS":0,
      "bytesPending":0,
      "putsPending":0,
      "bucketsPending":0,
      "copyTableCompletionPercentage":100,
      "numTablets":1,
      "numRows":4,
      "totalSize":24576
    }
  ]
}
```

Run mapr verifyindex

If `maprcli table index list` shows that an index is lagging, use the [mapr verifyindex](#) command to gather more information. The following example illustrates the output in the case where an index is lagging. The following updates have not yet propagated to the index:

- Document with `_id=997` not yet inserted into the index.
- Update to the `city` field in document with `_id=998` not yet propagated to the index.

```
// Display contents of parent JSON table
# mapr dbshell

maprdb root:> find /t1
{"_id":"1000","city":"city3","misc":{"a":"misc.a","b":2}}
{"_id":"997","city":"city3","misc":{"a":"misc.a","b":2}}
{"_id":"998","city":"city4","misc":{"a":"misc.a","b":2}}
{"_id":"999","city":"city3","misc":{"a":"misc.a","b":2}}
4 document(s) found.

// Display contents of an index that is lagging.
// Document with _id=997 is missing from the index and
// there is a mismatch in the index data for document with _id=998
maprdb root:> indexscan /t1 --indexname i2
{"_id":"1000","city":"city3"}
{"_id":"998","city":"city3"}
{"_id":"999","city":"city3"}
3 document(s) found.
maprdb root:> quit
```

```
// Output of verifyindex
# mapr verifyindex -path /t1 -index i2

Missing Document in Index:
{"_id":"997","city":"city3"}

Mismatch Document Found!!
Table side-->{"_id":"998","city":"city4"}
Index side-->{"_id":"998","city":"city3"}

Number of rows in table but not in index: 1
Number of rows in index but not in table: 0
Mismatch row count: 1
```

Troubleshooting Secondary Index Encoding Errors

This section describes how to locate secondary index encoding errors in log files, and then resolve them.

About this task

Unresolved secondary index encoding errors can result in queries returning incomplete results. See [Secondary Index Encoding Error](#) on page 3414 for details.

To troubleshoot secondary index encoding errors, follow these steps:

Procedure

1. Determine whether any table has index encoding alarms by using one of the following two options:

- Run the following grep command, searching for the strings index and encoding in the mfs.log-5 file:

```
# grep -i "index.*encoding" /opt/mapr/logs/mfs.log-5
2018-07-10 11:06:07,7042 INFO DB db/repl/aragggregator.cc:524 Table
2050.43.262440 hit index row-key encoding error
2018-07-10 11:06:07,7042 INFO DB db/repl/aragggregator.cc:914 Raising
alarm VOLUME_ALARM_TABLE_INDEX_ENCODING_ERROR for volume 195503497
```

The fid, 2050.43.262440, in the sample output indicates the table corresponding to the alarm. If you are not sure which table this corresponds to, you can convert the fid to a table path by following the instructions at [Converting fid and valid](#) on page 3634.

- Check for any table index encoding alarms in the Data Fabric Control System, as described at [Viewing Active Table Replication Alarms](#) on page 1957.

The alarm details indicate the table corresponding to the alarm.

- Find the index on the table from step 1 that is causing the error.

Run [dbshell indexscan](#) on page 7414 with `--mode` set to `err` on each index to see the index's error output. You need to run the command multiple times if a table has multiple indexes with errors.

For example, if `table1` has three secondary indexes and all three secondary indexes have errors, you must run `indexscan` three times:

```
indexscan /table1 --indexname index1 --mode err
indexscan /table1 --indexname index2 --mode err
indexscan /table1 --indexname index3 --mode err
```

The following example shows error output from running the `dbshell indexscan` command:

```
maprdb root:> indexscan /IndexEncodingErrorAlarmsTest1/tab1 --indexname
idx1 --mode err
{"_id":"100", "$ERROR":"Index field 1: INVALID_CAST"}
```

- Address the identified errors by attempting the following suggested resolutions:

Error	Suggested Resolutions
KEY_TOO_LONG: The collective size of the index key is limited to less than 32 KB.	<ul style="list-style-type: none"> Reinsert the row in the JSON table so the collective size of all the indexed fields is less than 32 KB. Redesign the secondary index so fields with large values are included fields instead of indexed fields. Reduce the number of indexed fields in the secondary index.
INVALID_CAST: An error was encountered applying the CAST function on an indexed field.	<ul style="list-style-type: none"> Verify that you have specified the correct types when using the CAST function with indexed fields. If the types are correct, reinsert the row in the JSON table so the values of indexed fields can be cast to the specified type. <p>See Using Casts in Secondary Indexes on page 767.</p>

Adjusting Memory Settings in the OJAI Distributed Query Service

This section describes how to verify, through log output, that your OJAI query is running out of memory due to memory limits in the OJAI Distributed Query Service. It then describes how to adjust the memory settings in the service.

Procedure

1. Before adjusting the OJAI Distributed Query Service memory settings, first confirm that your query has run out of memory due to limits in the service.

You should see output like the following in your client application log:

```
15:32:46.465 [Thread-21] - Error caused in scan Drill submissionFailed
for "select t.`$$ENC00FIAF62LE`,t.`$$document` from dfs.`/tables/
business` t where ((t.`city` = 'Currie') and (t.`state` = 'PA') and
(t.`review_count` > 5100)) limit 1
org.ojai.exceptions.OjaiException: Drill submissionFailed for "select
t.`$$ENC00FIAF62LE`,t.`$$document` from dfs.`/tables/business` t where
((t.`city` = 'Currie') and (t.`state` = 'PA') and (t.`review_count` >
5100)) limit 128" please ch

java.util.concurrent.ThreadPoolExecutor$Worker.run(ThreadPoolExecutor.jav
a:617)
    at java.lang.Thread.run(Thread.java:745)
Caused by: org.apache.drill.common.exceptions.UserRemoteException:
RESOURCE ERROR: One or more nodes ran out of memory while executing the
query.

Failure trying to allocate initial reservation for Allocator. Attempted
to allocate 5000000 bytes and received an outcome of FAILED_LOCAL.
Fragment 0:0
```

In the OJAI Distributed Query Service, log files are in the /opt/mapr/drill/<drill-version>/logs/drillbit.log on each node where the Query Service is running.

You should see output like the following:

```
2017-10-07 15:32:41,693 [BitServer-3] INFO
o.a.drill.exec.ops.FragmentContext - User Error Occurred: One or more
nodes ran out of memory while executing the query. (Failure trying to
allocate initial reservation for Allocator. Attempted
org.apache.drill.common.exceptions.UserException: RESOURCE ERROR: One or
more nodes ran out of memory while executing the query.

Failure trying to allocate initial reservation for Allocator. Attempted
to allocate 7000000 bytes and received an outcome of FAILED_LOCAL.
Fragment 1:1
```

2. After confirming, increase the Query Service memory settings by editing the /opt/mapr/conf/conf.d/warden.drill-bits.conf file on each Drillbit node. The file contains the following entries:

```
service.env=DRILL_HEAP=3072m,DRILL_MAX_DIRECT_MEMORY=1024m,DRILLBIT_CODE_
CACHE_SIZE=512m
```

```
service.heapsize.min=4608
service.heapsize.max=4608
```

Perform the following steps on **each** Drillbit node:

- Modify DRILL_HEAP and DRILL_MAX_DIRECT_MEMORY in the `service.env` entry based on your requirements.
- Update `service.heapsize.min` and `service.heapsize.max` to reflect the updates you made. The numbers sum to the 3 memory settings in the `service.env` entry.
- Restart warden on the node by running the following command:

```
service mapr-warden restart
```

Listing Secondary Indexes

Describes how to list information about the secondary indexes created on HPE Data Fabric Database JSON tables.

About this task

You can view secondary indexes using the Control System or the `maprc li table index` commands. You need the following permissions.

- `readAce` on the volume
- `lookupdir` on directories in the table path

NOTE: The `mapr` user is not treated as a superuser. HPE Data Fabric Database does not allow the `mapr` user to perform this operation unless that user is given the relevant permission or permissions with access-control expressions.

Listing Indexes in the Control System

Procedure

- Log in to the Control System and go to the **Indexes** tab in the [table information page](#).

The list of indexes displays in the **All indexes** pane and for each index, the page displays the following:

Column Name	Column Description
Index Name	The name of the index
Fields Indexed	The number of fields on the JSON table that are indexed and used for ordering
Fields Covered	The number of fields on the JSON table that are indexed, but not used for ordering
State	The replication state of the index
Up to Date	Whether the index is up to date
Hashed	Whether the index is hashed
Size	The size of the index

What to do next

To view more details on individual indexes, see [Viewing Secondary Index Details](#) on page 1735.

Listing Indexes Using the CLI

About this task

The following is basic command for listing secondary indexes.

```
maprcli table index list
    -path <path>
    -refreshnow < true | false >
```

See [table index list](#) on page 2821 for more information.

Viewing Secondary Index Details

Describes how to use the Control System to view more specific details on secondary indexes.

About this task

You can view secondary index details using the Control System.

Procedure

- 1. Go to the **Indexes** tab in the [table information page](#) for the JSON table.
- 2. Click the name of the index to display the details.
The page displays **Summary** and **Metrics** tabs.

Summary

The **Summary** tab displays the following:

Throughput - By Op Type	See Viewing Throughput by Operation Type Using the Control System on page 1941
Region Distribution	See Viewing Region Distribution on page 1944.
SETTINGS AND AUDITING	Displays the index name, whether or not the index is hashed and if hashed, the number of hashed partitions, the status of the index and if the index is current, and the number of bytes, puts, and buckets that are yet to be replicated to the index.
INCLUDED FIELDS	The fields in the JSON table that are indexed, but not used for ordering.
FIELDS INDEXED	The fields in the JSON table that are indexed and used for ordering.

Metrics

The **Summary** tab displays charts for the secondary index metrics. For more information, see [Viewing Secondary Index Metrics](#) on page 1943.

Removing Secondary Indexes on JSON Tables

Describes how to remove secondary indexes that are no longer needed.

About this task

You can remove secondary indexes using the Control System or the `maprc li table index` commands. You need the following permissions.

- `readAce` on the volume
- `lookupdir` on directories in the table path
- `indexperm` permission on the table, if you did not create the table

NOTE: The `mapr` user is not treated as a superuser. HPE Data Fabric Database does not allow the `mapr` user to perform this operation unless that user is given the relevant permission or permissions with access-control expressions.

Removing Indexes Using the Control System**Procedure**

1. Log in to the Control System and go to the **Indexes** tab in the [table information page](#).
2. Select the indexes to remove and click **Remove Index**.
The **Remove Index** confirmation window displays.
3. Review the index(es) to remove and click **Remove Index**.

Removing Indexes Using the CLI**About this task**

The following is the basic command for removing a secondary index on a JSON table.

```
maprc li table index remove
-path <path>
-index <index name>
```

See [table index remove](#) on page 2824 for more information.

Administering Change Data Capture

This topic covers the Control System and `maprc li` tools for managing the Change Data Capture (CDC) feature.

The following topics provide information you need to understand the CDC feature, to setup and use CDC and the `maprc li` commands used to perform tasks.

1. [Learning about CDC](#)
2. [Setting up the CDC environment](#)
3. [Consuming CDC changed data records](#)
4. [Using dbshell to perform CRUD operations on HPE Data Fabric Database JSON tables](#)
5. [Developing client applications for HPE Data Fabric Database JSON tables.](#)
6. [Using hbshell to perform CRUD operations on HPE Data Fabric Database binary tables.](#)
7. [Developing client applications for HPE Data Fabric Database binary tables.](#)

Additional Information

- [table changelog](#) on page 2799: The `maprccli table changelog` commands for managing the changelog relationship between the source table and the destination stream topic.

Setting Up CDC

Describes the requirements and how to set up Change Data Capture (CDC).

To set up the Change Data Capture (CDC) feature, the following must exist or be created:

- HPE Data Fabric Database source table (JSON or binary)
- HPE Data Fabric Streams changelog stream
- HPE Data Fabric Streams stream topic

- HPE Data Fabric Database table changelog relationship between the source table and the destination stream topic

Before Setting Up CDC

The destination HPE Data Fabric Streams stream can be in the same cluster as the HPE Data Fabric Database source table or it can be on a remote HPE Data Fabric cluster. Regardless of where the stream is located, propagating changed data requires a gateway.

Typically, gateways are setup by installing the gateway on the destination cluster and specifying the gateway node(s) on the source cluster. However, if the stream and the HPE Data Fabric Database source table are in the same cluster, install the gateway on that cluster and specify the gateway nodes(s) in the cluster. See [Administering Data Fabric Gateways](#) on page 1787 and [Configuring Gateways for Table and Stream Replication](#) on page 1789.

The following diagram shows a simple CDC data model with one source table to one destination topic on one stream; however, more complex CDC scenarios can be implemented with multiple gateways. See [Data Modeling and CDC](#) on page 814.

IMPORTANT: If you have a secure cluster, secure configuration must be setup. See [Configuring Secure Clusters for Cross-Cluster Mirroring and Replication](#) on page 2226.

Create Table

An HPE Data Fabric Database table (JSON or binary) must be established for the CDC data. You can create a new table and add data or use an existing table with data. See [maprccli table create](#) for creating a new table or use the Control System. Example code is provided for completing this task using either the maprccli or REST. Alternatively, depending on whether you are establishing JSON documents or binary files, you can use the following:

- [maprccli dbshell for HPE Data Fabric Database JSON documents](#)
- [hbshell for HPE Data Fabric Database binary data](#)

ATTENTION: Ensure that a volume exists and mounted for both tables and streams. Even though HPE Data Fabric Database tables and HPE Data Fabric Streams stream can exist in the same volume, for organizational purposes, you could create separate volumes for both tables and streams.

The following code examples show how to:

- Create and mount a volume for a source table.

- Create a new binary table. The `-tabletype` parameter's default setting is binary so you don't need to specify this parameter.
- Create a new JSON table.

CLI

```
// Create Volume for table
maprccli volume create -name
tableVolume -path /tableVolume

// Create Binary table
maprccli table create -path /
tableVolume/cdcTable

// Create JSON table
maprccli table create -path /
tableVolume/cdcTable -tabletype json
```

REST

```
// Create Volume for table
https://10.10.100.17:8443/rest/
volume/create?name=tableVolume&path=/
tableVolume

// Create Binary table
https://10.10.100.17:8443/rest/table/
create?path=/tableVolume/cdcTable

// Create JSON table
https://10.10.100.17:8443/rest/
table/create?path=/tableVolume/
cdcTable&tabletype=json
```

Create Stream

An HPE Data Fabric Streams changelog stream must be created for the propagated changed data records using the `maprccli stream create -ischangelog` parameter. See [maprccli stream create](#) or use the Control System.

NOTE: Ensure that a volume exists and mounted for both tables and streams. Even though HPE Data Fabric Database tables and HPE Data Fabric Streams stream can exist in the same volume, for organizational purposes, you could create separate volumes for tables and streams.

IMPORTANT: The changelog stream's default partitions can impact how many partitions a stream topic can have. This is because once you create a stream topic for a changelog stream, the number of topic partitions is *locked*. The number of topic partitions cannot change.

- If the `stream topic create` command is used to create a stream topic, then the number of topic partitions can be set at creation time and then is *locked*.
- If the `table changelog add` command is used to add a stream topic (as well as establish a relationship between the source table and the changelog stream), then the number of topic partitions is inherited from the changelog stream and is *locked*.

The following code examples show how to:

- Create and mount a volume for a changelog stream.
- Create a changelog stream using the default partitions value of one (1).

- Create a changelog stream changing the default partitions to three (3).

CLI

```
// Create Volume for stream
maprcli volume create -name
streamVolume -path /streamVolume

// Create stream (default partitions:
1)
maprcli
stream create -path /streamVolume/
changelogStream -ischangelog true

// Create stream (default
partitions: 3)
maprcli
stream create -path /streamVolume/
changelogStream -ischangelog
true -defaultpartitions 3
```

REST

```
// Create Volume for stream
https://10.10.100.17:8443/rest/volume/
create?name=streamVolume&path=/
streamVolume

// Create stream (default partitions:
1)
https://10.10.100.17:8443/rest/stream/
create?path=/streamVolume/
changelogStream&ischangelog=true

// Create stream (default partitions:
3)
https://10.10.100.17:8443/rest/stream/
create?path=/streamVolume/
changelogStream&ischangelog=true&defau
ltpartitions=3
```

Create Topic

An HPE Data Fabric Streams stream topic must be created for the changed data records. This can be accomplished in a variety of ways:

- Use the [maprcli table changelog add](#) command. This command establishes a changelog relationship between the source table and the destination stream topic.
- Use the [maprcli stream topic create](#) command.
- Use the REST equivalent of the above maprcli commands.
- Use the Control System.

IMPORTANT: Once a changelog relationship is established between the source table and the destination stream topic, the number of topic partitions is *locked*. (The `maprcli table changelog add` command is used to establish the changelog relationship.) The `stream topic edit` command can not be used to modify the topic's number of partitions.

The following describes when to create a stream topic a specific way.

- If the changelog stream's default partitions are acceptable for the stream topic (because the topic inherits the stream's default partitions), you can either:
 - Go directly to adding the changelog relationship with the `maprcli table changelog add` command and create the topic there.
 - Create the topic with the `stream topic create` command and *not* specify the `-partitions` parameter.
- If you want to change the topic's partitions, create the topic with the `stream topic create` command and set the `-partitions` parameter.
- If you use the Control System, either of the above methods are available.

The following code examples show how to create a stream topic and change the default partition to five (5).

CLI

```
// Create topic (default partitions: 5
maprcli stream topic create -path /
streamVolume/changelogStream -topic
cdcTopic1 -partitions 5
```

REST

```
// Create topic (default partitions: 5
https://10.10.100.17:8443/rest/stream/
topic/create?path=/streamVolume/
changelogStream&topic=cdcTopic1&partit
ions=5
```

Add Changelog

A table changelog relationship must be added between the source table and the destination stream topic by using the `maprcli table changelog add` command or the Control System. By adding a table changelog relationship, you are creating an environment that propagates changed data records from a source table to an HPE Data Fabric Streams stream topic.

- If you are creating a changelog relationship and the stream topic *does not* exist, specify the stream path and topic.
- If you are creating a changelog relationship and the stream topic *does* exist, specify the stream path and topic AND the `-useexistingtopic` parameter. The `-useexistingtopic` parameter can only be used with a changelog stream's newly created topic or a previous changelog stream topic *for the same source table*.

NOTE: Propagation of existing table data is enabled by default. If you do *not* want to propagate existing source table data, set the `-propagateexistingdata` parameter to **false**. The default is true.

NOTE: Propagation is enabled as soon as the table changelog relationship is added. If you do *not* want propagation to begin, set the `-pause` parameter to **true**. The change data records are stored in a bucket until you resume the changelog relationship; at this point, the stored change data records are propagated to the stream topic. See [table changelog resume](#) on page 2806 for more information.

The following examples show you how to:

- Create a changelog relationship between the source table and the destination stream topic, where the stream topic *does not* exist.

- Create a changelog relationship between the source table and the destination stream topic, where the stream topic *does* exist.

IMPORTANT: The examples show streams in a local cluster. To specify streams in a destination (remote) cluster, the path format is `/mapr/<remote-cluster>/path/to/stream:topic`.

CLI

```
maprcli table changelog add -path /
tableVolume/cdcTable -changelog /
streamVolume/changelogStream:cdcTopic1

maprcli table changelog add -path /
tableVolume/cdcTable -changelog /
streamVolume/
changelogStream:cdcTopic1 -useexisting
topic true
```

REST

```
https://10.10.100.17:8443/rest/table/
changelog/add?path=/tableVolume/
cdcTable&changelog=/streamVolume/
changelogStream:cdcTopic1

https://10.10.100.17:8443/rest/table/
changelog/add?path=/tableVolume/
cdcTable&changelog=/streamVolume/
changelogStream:cdcTopic1&useexistingt
opic=true
```

The following example verifies that the table changelog relationship exists:

```
maprcli table changelog list -path /tableVolume/cdcTable
```

What's Next: Modifying and Consuming Data

To have CDC changed data records to consume, you need to perform inserts, updates, and deletes on the HPE Data Fabric Database table data. See CRUD operations on documents using `mapr dbshell` for JSON documents, `mapr hbshell` for binary data, Java applications for HPE Data Fabric Database JSON, C or Java applications for HPE Data Fabric Database Binary.

An HPE Data Fabric Streams Kafka/OJAI consumer application subscribes to the topic and consumes the change data records. See [Consuming CDC Records](#) on page 3933 for more information.

Example: Setting Up CDC with Default Topic Partitions

This example creates the following: a volume for a HPE Data Fabric Database table, a HPE Data Fabric Database JSON table, a HPE Data Fabric Streams changelog stream without changing the default partitions, creates a topic while adding a table changelog relationship from the source table to the destination stream topic and and views the changelog information.

CLI Example

```
// Creating and mounting a volume for the source table
maprcli volume create -name tableVolume -path /tableVolume

// Creating and mounting a volume for the destination stream
maprcli volume create -name streamVolume -path /streamVolume

// Creating a new JSON table
maprcli table create -path /tableVolume/cdcTable -tabletype json
```

```
// Creating a stream for CDC data
maprcli stream create -path /streamVolume/changelogStream -ischangelog
true

// Creating a changelog relationship between the source table and the stream
maprcli table changelog add -path /tableVolume/cdcTable -changelog /
streamVolume/changelogStream:cdcTopic1

// Viewing the changelog information
maprcli table changelog info -changelog /streamVolume/
changelogStream:cdcTopic1 -json
```

REST Example

```
// Creating and mounting a volume for the source table
https://10.10.100.17:8443/rest/volume/create?name=tableVolume&path=/
tableVolume

// Creating and mounting a volume for the destination stream
https://10.10.100.17:8443/rest/volume/create?name=streamVolume&path=/
streamVolume

// Creating a stream for CDC data
https://10.10.100.17:8443/rest/stream/create?path=/streamVolume/
changelogStream&ischangelog=true

// Creating a changelog relationship between the source table and the stream
https://10.10.100.17:8443/rest/table/changelog/add?path=/tableVolume/
cdcTable&changelog=/streamVolume/changelogStream:cdcTopic1

// Viewing the changelog information
https://10.10.100.17:8443/rest/table/changelog/info?changelog=/
streamVolume/changelogStream:cdcTopic1
```

Example: Setting Up CDC with Non-default Topic Partitions

This example creates the following: a volume for a HPE Data Fabric Database table, a HPE Data Fabric Database JSON table, a HPE Data Fabric Streams changelog stream with default partitions, a stream topic with custom partitions, a table changelog relationship from the source table to the destination stream topic, and views the changelog information.

CLI Example

```
// Creating and mounting a volume for the source table
maprcli volume create -name tableVolume -path /tableVolume

// Creating and mounting a volume for the destination stream
maprcli volume create -name streamVolume -path /streamVolume

// Creating a new JSON table
maprcli table create -path /tableVolume/cdcTable -tabletype json

// Creating a stream for CDC data
maprcli stream create -path /streamVolume/changelogStream -ischangelog
true -defaultpartitions 3

// Creating a stream topic that overrides the stream's default partitions
maprcli stream topic create -path /streamVolume/changelogStream -topic
cdcTopic1 -partitions 5

// Creating a changelog relationship between the source table and the
```

```
stream plus using an existing topic that has custom partitions
maprccli table changelog add -path /tableVolume/cdcTable -changelog /
streamVolume/changelogStream:cdcTopic1 -useexistingtopic true

// Viewing the changelog information
maprccli table changelog info -changelog /streamVolume/
changelogStream:cdcTopic1 -json
```

REST Example

```
// Creating and mounting a volume for the source table
https://10.10.100.17:8443/rest/volume/create?name=tableVolume&path=/
tableVolume

// Creating and mounting a volume for the destination stream
https://10.10.100.17:8443/rest/volume/create?name=streamVolume&path=/
streamVolume

// Creating a stream for CDC data
https://10.10.100.17:8443/rest/stream/create?path=/streamVolume/
changelogStream&ischangelog=true&defaultpartitions=3

// Creating a stream topic that overrides the stream's default partitions
https://10.10.100.17:8443/rest/stream/topic/create?path=/streamVolume/
changelogStream&topic=cdcTopic1&partitions=5

// Creating a changelog relationship between the source table and the
stream plus using an existing topic that has custom partitions
https://10.10.100.17:8443/
rest/table/changelog/add?path=/tableVolume/cdcTable&changelog=/streamVolume/
changelogStream:cdcTopic1&useexistingtopic=true

// Viewing the changelog information
https://10.10.100.17:8443/rest/table/changelog/info?changelog=/
streamVolume/changelogStream:cdcTopic1
```

Managing Table Changelogs

Describes how to manage CDC table changelogs through the Control System and maprccli.

Adding a Change Data Log

Explains how to add a change data log using the Control System and the CLI.

About this task

To add a change data log, you must have the following permissions:

- **Replication Access** (UI) or `replperm` (CLI) on the source table on the source cluster
- **Topic** (UI) or `topicperm` (CLI) on the destination stream in the destination cluster

If you are a normal user and want to create a changelog between your own HPE Data Fabric Database table and someone else's stream topic, you must have **Topic** (UI) permission or `topicperm` (CLI) on the destination stream.

Adding a Change Data Log Using the Control System

Procedure

1. Log in to the Control System and go to the **Change Data Capture** tab in the [table information page](#).

2. Click **Add Change Log** to display the **Add Change Log** page.

3. Set values for the following.

Destination Cluster	(Required) The path to the cluster on which the changelog stream exists. If the destination stream is on a remote secure cluster, then a gateway and secure configuration must first be setup. For more information, see Table Replication on page 820, Administering Data Fabric Gateways on page 1787, and Configuring Secure Clusters for Cross-Cluster Mirroring and Replication on page 2226.
Destination Stream Topic Name	(Required) The target of the changelog stream, specified as <stream_path>:<topic_name>, to which all change data records will be published. The stream must exist as a changelog stream or the operation fails.
Publish to Existing Topic	Whether (Yes) or not (No) to publish to existing topic. If value is No and the topic does not already exist, it will be created.
Publish Existing Data	Whether (Yes) or not (No) to initiate publishing of the existing data to the stream. If value is No , only new changes will be propagated.
Defer Publishing	Whether (Yes) or not (No) to pause propagation after creating the change log.
Throttle	Whether (Yes) or not (No) the data transfer to the stream for this change log must be throttled.
Synchronously	Whether (Yes) or not (No) to acknowledge the client writes to the table before the CDC gateway receives the data.
Encrypt on Wire	Whether (Yes) or not (No) the data transfer between file system and gateway for this change log is encrypted.
Compress on Wire	The compression scheme of the data transfer between file system and gateway for this change log instance.

4. Choose one of the following:

- For JSON table:
 - **Publish Entire Document** — to publish the entire document to the stream topic.
 - **Publish Selected Field Path** — to specify the paths to the fields to publish to the stream topic.
- For Binary table:
 - **Publish Entire Document** — to publish the entire document to the stream topic.
 - **Publish Selected Column Families** — to specify the column families to publish to the stream topic.

5. Click **Add Change Log**.

*Adding a Change Data Log Using the CLI and REST API***About this task**

The basic command to add a change data log to a table is:

```
maprcli table changelog add
```

For complete reference, see [table changelog add](#) on page 2799.

Viewing the List of Change Logs

Explains how to view the list of change logs using the Control System or the CLI.

Viewing the List of Change Logs Using the Control System

Procedure

- Log in to the Control System and go to the **Change Data Capture** tab in the [table information page](#).
For each change log, the page displays the following:

Column Name	Column Description
Edit Change Log	Shortcut to the Edit Change Log window for editing a change log.
Paused	Specifies whether the change propagation is paused for the associated change log.
Destination Cluster	Specifies the destination cluster on which the stream exists.
Destination Stream Topic Name	Specifies the name of the stream associated with the change log.
Up to Date	Specifies whether (Yes) or not (No) the change log is up to date. If value is No , hover the cursor over the value to see the number of pending bytes, puts, and buckets.
Errors	Indicates whether there were any errors during change propagation.
Compression Type	The type of compression for data transfer between file system and gateway for the associated change data log instance
Synchronous	Specifies whether client writes to the table should be acknowledged before the CDC gateway receives the data.
Throttle	Specifies whether data transfer to the stream for the associated change data log is throttled.
Encrypted	Specifies whether the data transfer between file system and gateway for the associated change data log is encrypted.
Field Path	Specifies whether only specific field paths are being published to the stream topic.

*Retrieving the List of Change Logs Using the CLI or REST API***About this task**

The basic command to retrieve the list of change data logs is:

```
maprcli table changelog list
```

For complete reference, see [table changelog list](#) on page 2802.

Viewing Change Log Information

Explains how to view information about a specific change log using the CLI.

Retrieving Change Log Information Using the CLI or REST API

About this task

The basic command to retrieve the list of change data logs is:

```
maprcli table changelog info
```

For complete reference, see [table changelog info](#) on page 2801.

Editing a Change Log

Explains how to modify a change log associated with a table using either the Control System or the CLI.

Editing a Change Log Using the Control System

Procedure

1. Log in to the Control System and go to the **Change Data Capture** tab in the [table information page](#).
2. Click  associated with the change log to modify.
The **Edit Change Log** window displays.
3. Make the necessary changes to any of the following:

Throttle	Whether (Yes) or not (No) the data transfer must be throttled.
Synchronously	Whether (Yes) or not (No) to acknowledge the client writes to the table before the CDC gateway receives the data.
Encrypt on Wire	Whether (Yes) or not (No) the data transfer is encrypted.
Compress on Wire	The compression scheme of the data propagation.

4. Click **Save Changes** for the changes to take effect.

Editing a Change Log Using the CLI or REST API

About this task

The basic command to modify the change log is:

```
maprcli table changelog edit
```

For complete reference, see [table changelog edit](#).

Pausing Data Propagation

Explains how to pause data propagation using either the Control System or the CLI.

Pausing Data Propagation Using the Control System

Procedure

1. Log in to the Control System and go to the **Change Data Capture** tab in the [table information page](#).
2. Select the change log(s) to pause.
Selecting the checkbox next to a change log makes the **Actions** drop-down menu available.

3. Select **Pause Data Propagation** from the **Actions** drop-down menu to display the **Pause Data Capture** confirmation dialog.
4. Review the change log(s) to pause and click **Pause Data Capture**.

Pausing Data Propagation Using the CLI or REST API

About this task

The basic command to pause change data propagation is:

```
maprcli table changelog pause
```

For complete reference, see [table changelog pause](#).

Resuming Data Propagation

Explains how to resume a paused change log using either the Control System or the CLI.

Resuming Data Propagation Using the Control System

Procedure

1. Log in to the Control System and go to the **Change Data Capture** tab in the [table information page](#).
2. Select the change log(s) to pause.
Selecting the checkbox next to a change log makes the **Actions** drop-down menu available.
3. Select **Resume Data Propagation** from the **Actions** drop-down menu to display the **Resume Data Capture** confirmation dialog.
4. Review the change log(s) to resume and click **Resume Data Capture**.

Resuming Data Propagation Using the CLI or REST API

About this task

The basic command to resume change data propagation is:

```
maprcli table changelog resume
```

For complete reference, see [table changelog resume](#).

Removing Change Logs

Describes how to remove change logs using either the Control System or the CLI.

Removing Change Logs Using the Control System

Procedure

1. Log in to the Control System and go to the **Change Data Capture** tab in the [table information page](#).
2. Select the change log(s) to remove.
Selecting the checkbox next to a change log makes the **Actions** drop-down menu available.
3. Select **Remove Change Logs** from the **Actions** drop-down menu to display the **Remove Change Log(s)** confirmation dialog.
4. Review the change log(s) to remove and click **Remove Change Logs**.

Removing Change Logs Using the CLI or REST API

About this task

The basic command to remove a change log is:

```
maprcli table changelog remove
```

For complete reference, see [table changelog remove](#).

Troubleshooting Changelogs

checkandcreate topic failed with error 17

I'm getting a **checkandcreate topic** error while trying to edit a changelog topic.

Because the `maprcli table changelog add` command is an asynchronous command, the CDC relationship (same as replication relationship) involves storing information at both the source and destination sides. This results in the following behavior:

- When the `maprcli table changelog add` operation succeeds, it means that the add request is received. To check whether there is an error during the add operation, run the `maprcli table changelog list` operation.
- The `maprcli table changelog edit` operation only modifies the information on the source side, even if an error is display in the `maprcli table changelog list` output, the changelog can still be modified.

Troubleshooting methods:

- If the stream topic already exists in the destination and you are getting an error, delete the topic. The `maprcli table changelog add` operation automatically retries and finishes.
- If the error can not be fixed, delete the partial relationship from the source side with the `maprcli table changelog remove` operation and retry.

Enabling/Disabling Propagation

Propagation of existing table data is enabled by default. If you do *not* want to propagate existing source table data, set the `-propagateexistingdata` parameter to **false**. The default is true.

Propagation is enabled as soon as the table changelog relationship is added. If you do *not* want propagation to begin, set the `-pause` parameter to **true**. The change data records are stored in a bucket until you resume the changelog relationship; at this point, the stored change data records are propagated to the stream topic. See [table changelog resume](#) on page 2806 for more information.

Indexing HPE Data Fabric Database Binary Tables with Elasticsearch

As with MapR 6.0, HPE Data Fabric Database Elastic Search integration capability is deprecated and no longer available in the HPE Data Fabric Database product.

ATTENTION: HPE Data Fabric Database Change Data Capture (CDC) framework can be used to integrate with latest versions of Elasticsearch. See [Change Data Capture](#) on page 807 for more information.

Administering Streams

HPE Data Fabric Streams brings integrated publish and subscribe messaging to the HPE Data Fabric. Producer applications can publish messages to topics, which are logical collections of messages, and

Consumer applications can read those messages at their own pace. Topics are grouped into streams, for which administrators can apply security, retention, and replication policies.

1. [The HPE Data Fabric Streams and Apps section information and examples for developing Producer and Consumer applications.](#)
2. [The HPE Data Fabric Streams section provides conceptual information.](#)
3. [The Administering Streams section provides information about creating and managing streams, topics, and stream replication.](#)

Managing Streams

This topic provides information about managing streams in HPE Data Fabric Streams.

Creating a Stream

Explains how to create a stream using the Control System and the CLI.

About this task

Your decision about what streams to create should take into account whatever topics you want to replicate. Replication is between streams, not individual topics.

For example, suppose that you plan to create the stream `pollution_monitors` to collect various measurements about pollution levels in cities in Europe. However, during a planning session, the representative from Amsterdam says that her country wants to perform analyses of the data for its cities, and would like your company to replicate the data to its own HPE Data Fabric cluster, where its own consumers can read the replicated messages.

You would create a separate stream of topics that contain data from only the pollution sensors in the cities in that country. You might even decide to do the same for each center, in case other centers

eventually want to perform their own analyses, too. The streams you might decide to create could be `pollution_monitors_netherlands`, `pollution_monitors_sweden`, and so on.

Creating a Stream Using the Control System

About this task

To create a stream:

Procedure

1. Log in to the Control System and click **Create Stream** under **Data > Streams**.

NOTE: This option is not available in the Kubernetes version of the Control System.

The **Create New Stream** page displays.

2. Specify the following properties.

Property	Description
Stream Path	<p>The path and name of the stream to create.</p> <p>The path to the stream can include any character allowed by HPE Data Fabric. For example, <code>/my/path/with:/to/mystream:topic1</code> is valid, but <code>/my/path/with:/to/mystream:withcolon:topic1</code> is invalid.</p> <p>The name of the stream cannot include a colon (:) or a forward slash (/).</p>
Time To Live	<p>The amount of time to elapse between the publication of a message in a topic in this stream and the expiration of that message. Choose:</p> <ul style="list-style-type: none"> • Forever to retain messages indefinitely • Seconds to specify the number of seconds. A value of 0 causes messages to be retained indefinitely. <p>Messages that have expired are deleted during the next purge process. See Time-to-Live for Messages on page 847 for details.</p>
Compression	<p>The compression setting to use for the stream. Producer client libraries can bundle messages that are to be published on the same partition and compress them. The messages are sent to the server compressed, are stored compressed, are replicated to other containers compressed, and (if stream replication is configured) replicated to replica streams compressed. Consumer client libraries receive compressed data, decompresses it, and passes it to client applications.</p> <p>Choose one of the following:</p> <ul style="list-style-type: none"> • Inherited (to inherit from the directory where the stream is stored), which is the default setting • OFF (to disable compression) • LZF • LZF4 • ZLIB

Property	Description
Auto Create Topics	Whether (Yes) or not (No) to create a topic automatically when a producer tries to write the first message to it.
Default Partitions	<p>The default number of partitions to allocate to new topics in the stream. When deciding how many partitions to create by default for new topics in a stream, consider the expected volume of messages that will be published to the topics in the stream. High message volumes can be handled more efficiently by multiple consumers in consumer groups reading from multiple partitions than by individual consumers reading from a single partition.</p> <p> NOTE: You can override the default and specify a different number of partitions for each topic in the stream at the time of creating the topic or after creating the topic.</p>
Use for Change Log	Whether (Yes) or not (No) to create the stream for changed data records (as a result of inserts, updates, and deletes) in a HPE Data Fabric Database table.

3. Set up access to streams for users, groups, and roles.

For each user, group, and/or role, you can grant (by selecting the associated check box) or block (by deselecting the associated checkbox) the following types of access:

Administer	<p>Can modify the access-control expressions for the stream, set up replication from the stream, and modify attributes of the stream.</p> <p>This permission includes the topic permission.</p>
Copy Stream	Can copy data from one HPE Data Fabric stream to another HPE Data Fabric stream (using the <code>mapr copystream</code> utility) and compare the message IDs, metadata, and data in two HPE Data Fabric streams (using the <code>mapr diffstreams</code> utility).
Topic	Can create, edit, or remove topics in the stream.
Producer	Can publish messages to topics in the stream.
Consumer	Can listen to topics in the stream.

By default, all permissions are given to the user creating the stream. To grant or block access to other users, groups, and/or roles, choose one of the following:

- **Basic Settings:** Select the type — public, (OR) user, group, or role — from the drop-down list and grant read and/or write permissions.

TIP: Click  to create a copy of the associated access control setting. Click  to remove the associated access control expression.

Click **Add Another** to add permissions for another user, group, or role.

- **Advanced Settings:** Within empty strings (""), specify user (u), group (g), role (r), or public (p) who have and do not have read and/or write access using the following boolean expressions and subexpressions:
 - **!** — Negation operator.
 - **&** — AND operation.

- | — OR operation.

Use (), parentheses, for subexpressions.

Alternatively, click  associated with the type of access to use the **Create Access Control Expression** window to define access for public or users, group, and/or role.

NOTE: If you switch from Basic to Advanced, the basic settings, if any, will be carried over to the Advanced settings. If you switch from Advanced to Basic, all the settings will be lost because the subexpressions and AND (&) and negation (!) operations that are supported by Advanced settings are not supported in the Basic settings.

To add access control expressions for another user, group, or role, click **Add Another** and repeat this step.

4. Click **Create Stream** to create the stream.

Creating a Stream Using the CLI or REST API

About this task

The basic command to create a stream is:

```
maprcli stream create -path <Stream Path>
```

To run this command, your user ID must have the following permissions:

- readAce and writeAce on the volume
- lookupdir on directories in the path

For complete reference information, see [stream create](#) on page 2708.

Editing a Stream

Describes how to edit streams using the Control System and the CLI.

Editing a Stream Using the Control System

Procedure

1. Log in to the Control System and go to the [stream information page](#).
2. Click **Edit Stream**.
The **Edit Stream** page displays.
3. Make necessary changes to one or more of the following:

Property	Description
Time To Live	<p>The amount of time to elapse between the publication of a message in a topic in this stream and the expiration of that message. Choose:</p> <ul style="list-style-type: none"> • Forever to retain messages indefinitely • Seconds to specify the number of seconds. A value of 0 causes messages to be retained indefinitely. <p>Messages that have expired are deleted during the next purge process. See Time-to-Live for Messages on page 847 for details.</p>

Property	Description
Compression	<p>The compression setting to use for the stream. Producer client libraries can bundle messages that are to be published on the same partition and compress them. The messages are sent to the server compressed, are stored compressed, are replicated to other containers compressed, and (if stream replication is configured) replicated to replica streams compressed. Consumer client libraries receive compressed data, decompress it, and pass it to client applications.</p> <p>Choose from one of the following compression settings:</p> <ul style="list-style-type: none"> • Inherited (to inherit from the directory where the stream is stored), which is the default setting • OFF (to disable compression) • LZF • LZF4 • ZLIB
Auto Create Topics	Whether (Yes) or not (No) to create a topic automatically when a producer tries to write the first message to it.
Default Partitions	The default number of partitions to allocate to new topics in the stream.
Compact	Enable (Yes) or disable (No) log compaction. If enabled, obsolete records from topics are detected and deleted. By default, this is disabled (No) .

4. Add, modify, or remove access to streams for users, groups, and roles.

For each user, group, and/or role, you can grant (by selecting the associated check box) or deny (by deselecting the associated checkbox) the following types of access:

Administer	Can modify the ACE for the stream, set up replication from the stream, and modify attributes of the stream. This permission includes the topic permission.
Copy Stream	Can copy data from one HPE Data Fabric stream to another HPE Data Fabric stream (using the <code>mapr copystream</code> utility) and compare the message IDs, metadata, and data in two HPE Data Fabric streams (using the <code>mapr diffstreams</code> utility).
Topic	Can create, edit, or remove topics in the stream.
Producer	Can publish messages to topics in the stream.
Consumer	Can listen to topics in the stream.

To grant or deny access to users, groups, and/or roles, choose one of the following:

- Basic Settings: Select the type — public, (OR) user, group, or role — from the drop-down list and grant read and/or write permissions.

TIP: Click  to create a copy of the associated [ACE](#) setting. Click  to remove the associated [ACE](#).

Click **Add Another** to add permissions for another user, group, or role.

- **Advanced Settings:** Within empty strings (""), specify user (u), group (g), role (r), or public (p) who have and do not have read and/or write access using the following boolean expressions and subexpressions:
 - **!** — Negation operator.
 - **&** — AND operation.
 - **|** — OR operation.

Use (), parentheses, for subexpressions.

Alternatively, click  associated with the type of access to use the **Access Control Expression** window to define access for public or users, group, and/or role. See [Defining ACEs Using the Access Control Expression Builder](#) on page 2153 for more information.

NOTE: If you switch from Basic to Advanced, the basic settings, if any, are carried over to the Advanced settings. If you switch from Advanced to Basic, all the settings are lost because the subexpressions, and AND (&) and negation (!) operations that are supported by Advanced settings are not supported in the Basic settings.

To add [ACEs](#) for another user, group, or role, click **Add Another** and repeat this step.

5. Click **Save Changes** for the changes to take effect.

Editing a Stream Using the CLI or REST API

About this task

The basic command to edit a stream is

```
/opt/mapr/bin/maprcli stream edit -path <Stream Path>
```

To run this command, your user ID must have the following permissions:

- [readAce](#) and [writeAce](#) on the volume
- [lookupdir](#) on directories in the path
- [adminperm](#) permission on the stream

For complete reference information, see [stream edit](#) on page 2715.

Encrypting a Stream

Apply an additional layer of security to streams by encrypting them.

To set encryption on a stream:

1. Before encrypting a stream, ensure that wire-level security is enabled for the cluster. See [Enabling Wire-level Security](#) on page 2067.
2. Determine whether a directory or stream is encrypted by running the following command:

```
hadoop mfs -ls <path>
```

NOTE: Streams inherit the value of the `-setnetworkencryption` setting from the directory in which they are created.

3. If the directory is not encrypted, set the encryption on the streams with the following command:

```
hadoop mfs -setnetworkencryption on <path of stream>
```

Example

Suppose that the streams that you want to encrypt are all in the /test directory. You run this command to discover whether the directory is encrypted:

```
# hadoop mfs -lsd /test
Found 1 items
drwxr-xr-x Z U U - root root 0 2015-09-07 02:37 268435456 /test
p 2049.43.131260 localhost:5660
```

The second flag U after the permissions indicates that the directory test is unencrypted. Because you want to encrypt your stream to enhance data security, you run this command, which encrypts the entire directory:

```
hadoop mfs -setnetworkencryption on /test
```

If you run the -lsd command again, you will see that the U is replaced by an E, indicating that the directory is now encrypted:

```
# hadoop mfs -lsd /test
Found 1 items
drwxr-xr-x Z E U - root root 0 2015-09-07 02:40 268435456 /test
p 2049.43.131260 localhost:5660
```

Defining ACEs Using the Access Control Expression Builder

Describes how to build ACEs using the Expression Builder.

About this task

To define access control expressions using the **Access Control Expression** builder in the Control System:

Procedure

1. Choose **All** or **Any** (from the drop-down menu) of the settings to match for access.
Here:

All	AND (&) operation	Indicates that all of the conditions must be met for public or user, group, and role to access the volume.
Any	OR () operation	Indicates that any one of the conditions must be met for public or user, group, and role to access the volume.

2. Click:

+	To add an expression.
()	To add a subexpression.
x	To remove an expression or subexpression.

3. Select **Public** or **User**, **Group**, or **Role** from the drop-down menu and:

- a) Choose **Is** to grant or **Is not** to block access to the user, group, or role.
- b) Enter the name of the user, group, or role.

4. Click **Save Changes** to create an ACE.

Setting Whole Volume ACEs Using the CLI

About this task

See [Setting Whole Volume ACEs](#) on page 1627.

Setting Table ACEs Using the CLI

About this task

See [Enabling Table and Stream Authorizations with ACEs](#) on page 1625.

Setting Stream ACEs Using the CLI

About this task

See [Enabling Table and Stream Authorizations with ACEs](#) on page 1625.

Removing Streams

Explains how to delete a stream using either the Control System or the CLI.

About this task

Deleted streams cannot be recovered unless they were replicated before deletion. After a stream is deleted, producers will not be able to publish messages to topics in the stream, and consumers will not be able to read messages from topics in the stream.

Removing a Stream Using the Control System

About this task

Procedure

1. Log in to the Control System and go to the [stream information page](#).
2. Click **Remove Stream** to display the **Remove Stream** confirmation dialog.
3. Confirm the action by clicking **Remove Stream**.

Removing a Stream Using the CLI or REST API

About this task

The command to delete a stream is:

```
stream delete -path <Stream Path>
```

To run this command, your user ID must have the following permissions:

- [readAce](#) and [writeAce](#) on the volume
- [lookupdir](#) on directories in the path

For complete reference, see [stream delete](#) on page 2714.

Viewing a List of Streams

Describes how to view the list of streams using the Control System.

Listing Streams by Type

Procedure

1. Log in to the Control System and click **Data > Streams**.

NOTE: This option is not available in the Kubernetes version of the Control System.

2. Choose one of the following HPE Data Fabric Streams stream type:
 - **Multiple Topics** — to display the list of streams with multiple topics
 - **Single Topic** — to display the list of streams with a single topic

Listing Streams in a Volume

Procedure

1. Log in to the Control System and click **Data > Streams** to view all the volumes that you have access to.

NOTE: This option is not available in the Kubernetes version of the Control System.

For each volume, the pane displays the following:

Column Name	Column Description
Name	The name of the volume.
Type	The type. Value can be: <ul style="list-style-type: none"> • — Volume • — Directory • — Stream
Owner	The name of the owner.
Last Modified	The last modification date and timestamp.

2. Click the name of the volume (to browse to the path to the stream) or enter the name of the volume in the text field.

The streams in the selected volume display. If necessary, click to return to **All** volumes view.

Listing Streams by Stream Path

About this task

Procedure

1. Log in to the Control System and click **Data > Streams**.

NOTE: This option is not available in the Kubernetes version of the Control System.

2. Enter the path to the stream in the search field and click **GO**.

Viewing Stream Information

Explains how to view stream information including stream properties, topics, and replication settings using the Control System and the CLI.

Viewing Stream Information Using the Control System

About this task

To view stream information:

Procedure

1. Log in to the Control System and click **Data > Streams**.

NOTE: This option is not available in the Kubernetes version of the Control System.

2. Locate the stream ([by searching or browsing the volumes or by entering the full path to the stream](#)) and click on the stream name.

The stream information page displays the following tabs:

- Summary
- [Topics](#)
- [Replication](#)

You can:

- [Modify the stream](#)
- [Remove the stream](#)

The **Summary** tab displays:

- The active and recent alarms in the **Alarms** pane.
- The stream settings and permissions in the **Detail** pane.

Retrieving Stream Information Using the CLI or REST API

About this task

The basic command to retrieve stream information is:

```
maprcli stream info -path <Stream Path>
```

To run this command, your user ID must have the following permissions:

- [readAce](#) on the volume
- [lookupdir](#) on directories in the path

- **adminperm**

When a user with this permission runs the command, the output includes the access-control expressions for the **adminperm** and **topicperm** permissions.

produceperm, consumeperm, or topicperm

When a user with one of these permissions runs the command, the output does not include any access-control expressions.

For complete reference information, see [stream info](#) on page 2718.

Managing Topics

Topics are logical collections of messages. The following sections describe how to create and manage topics.

Adding a Topic to a Stream

Explains how to add a topic to a stream using either the Control System or the CLI.

Adding a Topic to a Stream Using the Control System

Procedure

1. Log in to the Control System and go to the **Topics** tab in the [stream information page](#).
2. Click **Add Topic** in the **All** topics pane.
3. Specify the name of the topic in the **Topic Name** field.
A name can include alphanumeric characters and the following characters: . (dot), _ (underscore), and - (hyphen).
4. Specify the number of partitions to use for the topic.
After you create the topic, you can increase the number of partitions, but you cannot reduce the number. If the topic is associated with a stream for change log, you cannot modify the partitions after you create the topic.
5. Click **Add Topic** to create the topic.

Adding a Topic to a Stream Using the CLI or the REST API

About this task

The basic command to create a topic is:

```
maprcli stream topic create -path <Stream Path> -topic <Topic Name>
```

For complete reference information, see [stream topic create](#) on page 2731.

Removing Topics in a Stream

Describes how to delete one or more topics from the stream using either the Control System or the CLI.

About this task

Consumers do not have to stop consuming from a topic before the topic is deleted.

Removing Topics in a Stream Using the Control System

Procedure

1. Log in to the Control System and go to the **Topics** tab in the [stream information page](#).
2. Select the topics to remove in the **All** topics pane and click **Remove Topic(s)**.
The **Remove Topic(s)** confirmation window displays.
3. Verify the list of topics and click **Remove Topic**.
The topic and the messages are immediately deleted.

Removing Topics in a Stream Using the CLI or REST API

About this task

The command to delete a topic is:

```
maprcli stream topic delete -path <Stream Path> -topic <Topic Name>
```

For complete reference information, see [stream topic delete](#) on page 2733.

Viewing the List of Topics in a Stream

Explains how to view the list of topics in a stream using the Control System and the CLI.

Viewing the List of Topics in a Stream Using the Control System

Procedure

- Log in to the Control System and go to the **Topics** tab in the [stream information page](#).
The All topics pane displays the list of topics in the stream and for each topic, the pane displays the following:

Column Name	Column Description
Topic Name	The name of the topic.
Maximum Lag	The consumer lag time (in milliseconds).
Partitions	The number of partitions in the topic.
Consumers	The number of consumers for the topic.
Physical Size	The physical size (in MB) of the topic.

You can view a topic from the list of topics by entering the topic name in the search field. You can also:

- [Add](#) a topic to the stream.
- [Remove](#) one or more topics.
- [Modify](#) the number of partitions for a topic.

Viewing the List of Topics in a Stream Using the CLI or REST API

About this task

The command to view the list of topics in a stream is:

```
stream topic list -path <Stream Path>
```

For complete reference information, see [stream topic list](#) on page 2737.

Modifying Topic Partitions

Explains how to modify the number of partitions using the Control System and the CLI.

About this task

NOTE: In general, you can increase the number of partitions, but you cannot reduce the number. However, if the topic is associated with a stream for change logs, you *cannot* modify the number of partitions.

Modifying Topic Partitions Using the Control System

Procedure

1. Log in to the Control System and go to the **Topics** tab in the [stream information page](#).
2. Click  in the **Partitions** column for the topic.
The **Edit Partition** window displays.
3. Modify the number of partitions and click **Save Changes** for the changes to take effect.

Modifying Topic Partitions Using the CLI or REST API

About this task

The command to modify topic partitions is:

```
stream topic edit -path <stream path> -topic <topic name> -partitions
<number of partitions>
```

For complete reference information, see [stream topic edit](#) on page 2734.

Managing Stream Replication

This section contains topics about setting up stream replication and administering existing replicas.

The process to set up stream replication consists of 3

steps:

1. [Stream Replication](#) on page 866
2. [Preparing Clusters for Stream Replication](#) on page 1763
3. [Adding Stream Replicas](#) on page 1763
4. [Setting Up Stream Replication Using the CLI](#) on page 1766

After you set up replication, you can administer replicas using the Control System or the CLI. To view the replication status, run [stream replica list](#) on page 2725.

Preparing Clusters for Stream Replication

Configuring clusters for participation in the replication of HPE Data Fabric Streams streams involves configuring two or more gateways on destination clusters and, if the clusters are secure, setting up secure communications between the clusters.

Prerequisites

- Plan which replication topology you want to use: basic primary-secondary, multi-master, or a combination of these. For more information about replication topologies, see [Stream Replication](#) on page 866.
- Ensure that you have administrative authority on the clusters that you plan to use.
- Replicating streams requires the installation of gateways. For more information about installation requirements, see [Service Layout Guidelines for Replication](#) on page 86

Procedure

To configure clusters for replication between streams:

1. In the `mapr-clusters.conf` file on every node in your source cluster, add an entry that lists the CLDB nodes that are in the destination cluster.

NOTE:

This step is required so that the source cluster can communicate directly with the destination cluster's CLDB nodes. See [mapr-clusters.conf](#) on page 3370 for the format to use for the entries.

2. Configure gateways on the destination clusters.
See [Configuring Gateways for Table and Stream Replication](#).
3. **For secure clusters:** Optionally, configure source clusters so that you can locally run `maprccli` commands that are executed on the destination cluster.
See [Configuring Secure Clusters for Running Commands Remotely](#).
4. **For secure clusters:** Add one cross-cluster ticket to each source cluster for each cluster that it replicates to.
See [Configuring Secure Clusters for Cross-Cluster Mirroring and Replication](#).
5. Ensure that the user ID of the person who starts the replication process has the `readAce` permission on the volume where the source streams are located and the `writeAce` permission on the volumes where the replica streams are located. For information about how to set permissions on volumes, see [Setting Whole Volume ACEs](#) on page 1627.

Adding Stream Replicas

You can create stream replicas using the Control System and the CLI. When you add a replica using the Control System, you can also set up and start replication between a source and replica stream.

About this task

Before creating a replica:

1. Review the following:
 - [Modes of Stream Replication](#) on page 869
 - [Security for Stream Replication](#) on page 872
 - [Preparing Clusters for Stream Replication](#) on page 1763

**NOTE:**

- You must replicate all of the topics that are in a stream. You cannot select only a subset of topics to replicate.
- The maximum number of replicas that a stream can replicate to is 64.
- The maximum number of upstream sources that a replica can accept data from is 64.
- In
 - Multi-master replication, names of topics must be unique on all streams. Messages are assigned sequential offsets. The offsets for messages in a topic in one copy could conflict with the offsets for messages in the other copy. As a result, messages could be lost.
 - Many-to-one replication, topics with the same name should not be replicated to an aggregate replica.

Adding a Replica Using the Control System**About this task**

To add a replica using the Control System:

Procedure

1. Log in to the Control System and go to the **Replication** tab in the [Viewing Stream Information](#) on page 1759.
2. Click **Add Replica**.
The **Add Replica** page displays.
3. Specify the following settings.

Path to Source Stream	The path and name of the stream that you want to create a replica for.
Destination Cluster	The destination cluster for the replica, where gateways are configured to allow source cluster to send updates.
Path to Replica	The path and name of the replica stream.

Replication State	<p>Specify whether or not to start replication by choosing one of the following:</p> <ul style="list-style-type: none"> • Automatic Setup — Creates the stream on the destination cluster, registers the stream on the destination cluster as a replica, adds the current stream as an upstream source, copies the content of the current stream into the replica, and starts replication. In this case, the replica stream starts empty and accumulates messages over time. • Pause Replication — Creates the stream on the destination cluster, registers the stream on the destination cluster as a replica, adds the current stream as an upstream source, but prevents replication from immediately starting after. Pausing replica like this allows you to load the data into the replica from the current stream, after which you can restart replication. <p> NOTE: If you are interested only in the messages that are published to the source stream after replication starts, then you do not need to pause replication initially. However, if you want the full set of messages from the source stream that have not yet been purged or marked for deletion, then pause replication initially.</p>
Multi-Master Setup	<p>(Available only with Automatic Setup) Multi-master topology, in which there are two primary-secondary relationships, with each stream playing both the primary and secondary roles. Client applications update both streams and each stream replicates updates to the other.</p> <p>If this is not selected, stream replication will be basic primary-secondary topology. In this topology, you replicate in one direction.</p> <p>See Stream Replication on page 866 for more information.</p>

4. Select values for the following optional settings.

Throttle	<p>Specifies whether (Yes) or not (No) to throttle replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load. By default, throttling is disabled.</p> <p>Throttling has two effects, both of which allow HPE Data Fabric Streams to use more system resources to process new messages:</p> <ul style="list-style-type: none"> • Throttling slows down the rate at which changes to a stream are replicated. • Throttling slows down the rate at which messages to be replicated are read from disk.
Replicate Synchronously	<p>Specifies whether replication is synchronous (Yes) or asynchronous (No). The default value is asynchronous replication.</p>
Encrypt On Wire	<p>Specifies whether (Yes) or not (No) to enable on-wire encryption. By default, this is disabled (No). If you enable on-wire encryption, the local cluster and any other cluster that is part of the replication process must be enabled for security.</p>
Compress On Wire	<p>Specifies the type of compression to use when replicating messages.</p>

5. Click **Add Replica** to create the replica.

Adding a Replica Using the CLI or REST API

About this task

The basic command to create a replica is:

```
maprcli stream replica add -path <stream path> -replica <remote stream path>
```

To run this command, your user ID must have the following permissions on the:

- Source cluster:
 - [readAce](#) and [writeAce](#) on the volume
 - [lookupdir](#) on directories in the path
 - [adminperm](#) and [copyperm](#) permissions on the source stream
- Target cluster:
 - [readAce](#) and [writeAce](#) on the volume
 - [lookupdir](#) on directories in the path

For complete reference, see [stream replica add](#) on page 2719.

NOTE: You also have the option to set up replication with `maprcli table replica autoseup` which will set up and start replication. For more information, see [Setting Up Stream Replication Using the CLI](#) on page 1766.

Setting Up Stream Replication Using the CLI

Describes how to run the `maprcli stream replica autoseup` command to set up primary-secondary or multi-master replication from an existing source stream.

About this task

NOTE: This procedure describes how to use the `maprcli` to automatically set up stream replication. As an alternative, you can use the [Control System to automatically set up table replication](#) or use the `maprcli` command to [manually set up primary-secondary replication](#).

Before you begin, review the following requirements:

- You must replicate all of the topics that are in a stream. You cannot select only a subset of topics to replicate.
- The maximum number of replicas that a stream can replicate to is 64.
- The maximum number of upstream sources that a replica can accept data from is 64.
- In multi-master replication, names of topics must be unique on all streams. Messages are assigned sequential offsets. The offsets for messages in a topic in one copy could conflict with the offsets for messages in the other copy. As a result, messages could be lost.
- In many-to-one replication, topics with the same name should not be replicated to an aggregate replica.

In general, you should store your streams on their own volumes to avoid overlap with volume mirroring. Otherwise, if a source volume fails, you may have a scenario where a stream in the promoted mirror lags behind the stream's replica. See [Preparing Clusters for Table Replication](#) on page 1693 for more details.

Set up replication automatically by following these steps:

Procedure

1. Log into both the source and destination clusters.
2. Run the command `maprccli stream replica autoseup`:
 - For primary-secondary replication:

```
maprccli stream replica autoseup -path <path to source stream> -replica <path to replica stream>
```

For example, to set up primary-secondary replication from the activity stream in the sanfrancisco cluster to a new activity stream in the newyork cluster, you could use this command:

```
maprccli stream replica autoseup -path /mapr/sanfrancisco/activity -replica /mapr/newyork/activity
```

- For multi-master replication:

```
maprccli stream replica autoseup -path <path to source stream> -replica <path to replica stream> -multimaster yes
```

For example, to set up multi-master replication between the activity stream in the sanfrancisco cluster and a new activity stream in the newyork cluster, you could use this command:

```
maprccli stream replica autoseup -path /mapr/sanfrancisco/activity -replica /mapr/newyork/activity -multimaster yes
```

NOTE: The parameter `-multimaster` is an optional parameter that you use to set up multi-master replication.

NOTE: By default, `maprccli stream replica autoseup` sets up asynchronous replication. If you want to set up synchronous replication or use any of the other optional parameters, see [stream replica autoseup](#) on page 2721.

3. To check the replication status, run [stream replica list](#) on page 2725.

Setting Up Primary-Secondary Stream Replication Manually

Describes how to setup a primary-secondary stream replica that replicates in one direction.

About this task

Replica streams can be in a remote Data Fabric cluster or in the Data Fabric cluster where their source streams are located. All updates from a source stream arrive at a replica stream after having been authenticated at a gateway. Therefore, the `produceperm` access control expressions on the replica stream is irrelevant; gateways have the implicit authority to publish messages to topics in replica streams.

To set up primary-secondary replication of streams:

Procedure

1. Create the replica manually with the `maprcli stream create` command. Use the `-copymetafrom` option to ensure that the metadata for the replica is identical to the metadata for the source stream.

```
maprcli stream create -path <path to replica>
-copymetafrom <path to source stream>
```

For example, to create the replica activity in the newyork cluster and use the metadata from the source stream in the sanfrancisco cluster, you could use this command:

```
maprcli stream create -path /mapr/newyork/activity
-copymetafrom /mapr/sanfrancisco/activity
```

2. Register the replica as a replica of the source stream by running the `maprcli stream replica add` command.

```
maprcli stream replica add -path <path to source stream>
-replica <path to replica> -paused true
```

For example, to register the activity stream in the newyork cluster as a replica of the activity stream in the sanfrancisco cluster, you could use this command:

```
maprcli stream replica add -path /mapr/sanfrancisco/activity
-replica /mapr/newyork/activity -paused true
```

The `-paused` parameter ensures that replication does not start immediately after you register the source stream as a source for this replica. You do this registration in step 4.

3. Verify that you specified the correct replica by running the `maprcli stream replica list` command.

```
maprcli stream replica list -path <path to source stream>
```

To verify that the activity stream in the newyork cluster is a replica of the activity stream in the sanfrancisco cluster, you could look at the output of this command:

```
maprcli stream replica list -path /mapr/sanfrancisco/activity
```

4. Authorize replication between the streams by defining the source stream as the upstream stream for the replica by running the `maprcli stream upstream add` command.

Definition of the upstream stream ensures that a stream cannot replicate updates to any replica. Replication depends on a two-way agreement between the owners of the two streams.

```
maprcli stream upstream add -path <path to replica> -upstream
<path to source stream>
```

To add the activity stream in the sanfrancisco cluster as an upstream source for the activity stream in the newyork cluster:

```
maprcli stream upstream add -path /mapr/newyork/activity -upstream
/mapr/sanfrancisco/activity
```

5. Verify that you specified the correct source stream by running the `maprcli stream upstream list` command.

```
maprcli stream upstream list -path <path to the replica>
```

To verify this in our example scenario, you could use this command:

```
maprcli stream upstream list -path /mapr/newyork/activity
```

6. Load the replica with data from the source stream by using the [mapr copystream](#) on page 7455 utility.
7. Start replication with the command `maprcli stream replica resume`.

```
maprcli stream replica resume -path <path to the source stream>
-replica <path to the replica>
```

For our example scenario, you could use this command:

```
maprcli stream replica resume -path mapr/sanfrancisco/activity
-replica /mapr/newyork/activity
```

Viewing the List of Stream Replicas

Explains how to view the list of replicas for a stream using the Control System and the CLI.

Viewing the List of Stream Replicas Using the Control System

Procedure

- Log in to the Control System and go to the **Replication** tab in the [stream information page](#).

The **Replicas** pane displays the the list of replicas for the selected stream and for each replica, the pane displays the following:

Column Name	Column Description
Paused	Specifies whether replication is paused.
Destination Cluster & Type	The cluster on which the replica stream resides.
Destination Path	Specifies the name and path of the replica stream.
Status	<p>The status of the replica. Replicas can be in one of the following states:</p> <ul style="list-style-type: none"> In-Synch — indicates replica is in synch with the source stream and there are no more bytes to be sent from the source. Pending — indicates replica is waiting for some bytes to be sent from the source. You can hover over the status to determine the number of bytes, puts, and buckets pending. Broken — indicates there was an error during replication. If necessary, remove and re-create the replica.
Earliest	The date of the oldest message that has yet to be replicated.

Column Name	Column Description
Latest	The date of the newest message that has yet to be replicated.
Errors	Indicates if there were errors during replication.
Compression Type	The type of on-wire compression.
Synchronous	Specifies whether replication is synchronous.
Throttled	Specifies whether replication operations are throttled.
Encrypted	Specifies whether on-wire encryption is enabled.

Selecting the checkbox beside a replica makes the Actions drop-down menu available. You can:

- [Add](#) a replica
- [Edit](#) a replica
- [Pause](#) a replica
- [Resume](#) replication
- [Un-register](#) replica(s)
- [Set](#) current stream as an upstream source

Viewing the List of Stream Replicas Using the CLI or REST API

About this task

The command to pause a replication is:

```
maprcli stream replica pause -path <stream path> -replica <remote stream path>
```

For complete reference information, see [stream replica pause](#) on page 2727.

Editing a Stream Replica

Explains how to edit a stream replica using the Control System and the CLI to modify the way in which messages are replicated from the source stream to the replica.

Editing a Stream Replica Using the Control System

About this task

To un-register one or more stream replicas from the Control System:

Procedure

1. Log in to the Control System and go to the **Replication** tab in the [stream information page](#).
2. Click  associated with the replica to edit in the **Replicas** pane.
The **Edit Replica** page displays.
3. Make necessary changes to any of the following properties.

Path to Replica	Specify path and name of the replica stream.
------------------------	--

Throttle	<p>Enable (Yes) or disable (No) throttling of replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load. By default, throttling is disabled.</p> <p>Throttling has two effects, both of which allow HPE Data Fabric Streams to use more system resources to process new messages:</p> <ul style="list-style-type: none"> • Throttling slows down the rate at which changes to a stream are replicated. • Throttling slows down the rate at which messages to be replicated are read from disk.
Replicate Synchronously	Set up synchronous (Yes) or asynchronous (No) replication.
Encrypt On Wire	Enable (Yes) or disable (No) on-wire encryption. By default, this is disabled (No). If you enable on-wire encryption, the local cluster and any other cluster that is part of the replication process must be enabled for security.
Compress On Wire	Specify type of compression to use when replicating messages.

4. Click **Save Changes** for the changes to take effect.

Editing a Stream Replica Using the CLI or REST API

About this task

The basic command to modify a replica is:

```
stream replica edit -path <stream path> -replica <remote stream path>
```

For complete reference information, see [stream replica edit](#) on page 2723.

Removing Stream Replicas

Explains how to unregister one or more replicas using the Control System and the CLI.

Removing Stream Replicas Using the Control System

About this task

To un-register one or more stream replicas from the Control System:

Procedure

1. Log in to the Control System and go to the **Replication** tab in the [stream information page](#).
2. Select the replicas to remove in the **Replicas** pane.
Selecting the checkbox next to a replica makes the **Actions** drop-down menu available.
3. Select **Remove Replica(s)** from the **Actions** drop-down menu.
The **Remove Replica(s)** confirmation window displays.
4. Verify the list of replicas to remove and click **Remove Replica**.
This action un-registers the stream as the replica of the source stream.

Removing a Stream Replica Using the CLI or REST API

About this task

The command to remove a replica is:

```
stream replica remove -path <stream path> -replica <remote stream path>
```

For complete reference information, see [stream replica remove](#) on page 2728.

Pausing Stream Replication

Explains how to pause replication from a source stream to a replica stream using the Control System and the CLI.

Pausing Stream Replication Using the Control System

About this task

To pause one or more replications:

Procedure

1. Log in to the Control System and go to the **Replication** tab in the [stream information page](#).
2. Select the replicas to pause in the **Replicas** pane.
Selecting the checkbox next to a replica makes the **Actions** drop-down menu available.
3. Select **Pause Replication** from the **Actions** drop-down menu.
The **Pause Replication** confirmation window displays.
4. Verify the list of replicas to pause and click **Pause Replication**.
This action pauses replication from the source stream to the selected replica stream(s).

Pausing Stream Replication Using the CLI or REST API

About this task

The command to pause a replication is:

```
maprcli stream replica pause -path <stream path> -replica <remote stream path>
```

For complete reference information, see [stream replica pause](#) on page 2727.

Resuming Stream Replication

Explains how to resume replication from one stream to another stream using either the Control System or the CLI.

Resuming Stream Replication Using the Control System

About this task

To resume one or more replications:

Procedure

1. Log in to the Control System and go to the **Replication** tab in the [stream information page](#).
2. Select the replicas (in **Paused** state) in the **Replicas** pane.
Selecting the checkbox next to a replica makes the **Actions** drop-down menu available.
3. Select **Resume Replication** from the **Actions** drop-down menu.
The **Resume Replication** confirmation window displays.
4. Verify the list of replicas to resume and click **Resume Replication**.
This action resumes replication from the source stream to the selected replica stream(s).

Resuming Stream Replication Using the CLI or REST API

About this task

The command to resume a replication is:

```
maprcli stream replica resume -path <stream path> -replica <remote stream path>
```

For complete reference information, see [stream replica resume](#) on page 2728.

Managing Upstream Sources for Stream Replicas

You can set up a stream to be the upstream source for replicas. This is especially useful if you did not set up replication automatically when setting up replicas.

Set up Stream as Upstream Source

Describes how to set up the current stream as the upstream source for a replica if the replica was not set up to automatically resync with the current stream.

Setting Up Current Stream as Upstream Source for a Replica Using the Control System

About this task

To set up a stream as the upstream source for a replica:

Procedure

1. Go to the **Replication** tab in the [stream information page](#)
2. Select the checkbox beside the replica(s) that do not have the current stream configured as upstream source for automatic resync.
Selecting a checkbox next to a replica makes the **Actions** drop-down menu available.
3. Select **Set Current Stream as Upstream Source** from the **Actions** drop-down menu.
The **Set Current Stream as Upstream Source** dialog displays.
4. Review the list of selected replicas and click **Set Upstream Source**.
The current stream will automatically send updates to the replica(s).

Setting Up Stream as Upstream Source for a Replica Using the CLI or REST API

About this task

The basic command to set a table as the upstream source for a replica is:

```
maprcli stream upstream add -path <replica stream path> -upstream <source stream path>
```

See [stream upstream add](#) on page 2729 for complete reference information.

Adding Upstream Source for a Stream

Explains how to add an upstream source for a stream using either the Control Panel or the CLI.

About this task

You can register a stream as an upstream source for a stream using the Control System and the CLI. When you register a stream as an upstream source, the registered upstream source stream will send updates to the stream.

*Adding Upstream Source for a Stream Using the Control System***About this task**

To register a stream as an upstream source:

Procedure

1. Log in to the Control System and go the [stream information page](#).
2. Click **Add Upstream Source** in the **Upstream Sources** pane.
The **Add Upstream Sources** window displays.
3. Specify the path and name of the source stream in the **Upstream Source** field.
4. Click **Add Upstream Source** to register the source stream as an upstream source for this stream.

*Adding Upstream Source for a Stream Using the CLI or REST API***About this task**

The command to add an upstream source is:

```
maprcli stream upstream add -path <stream path> -upstream <upstream stream path>
```

For complete reference information, see [stream upstream add](#) on page 2729.

Listing all Upstream Sources for a Stream

Describes how to list all the upstream sources for a stream using the Control System and the CLI.

*Listing all Upstream Sources for a Stream Using the Control System***Procedure**

- Log in to the Control System and go to the **Replication** tab in the [stream information page](#).
The **Upstream Sources** pane displays the list of upstream sources for the selected stream and for each upstream source, the pane displays the following:

Column Name	Column Description
IDX	The index number of the upstream stream.
Upstream Source Cluster	The name of the Data Fabric cluster in which the upstream stream is located.
Upstream Source Path	The path and name of the upstream stream.
UUID	The upstream stream's universally unique identifier.

You can [add](#) an upstream source and by selecting the checkbox beside a stream, you can decouple the selected upstream stream.

*Listing all Upstream Sources for a Stream Using the CLI or REST API***About this task**

The command to list all upstream sources for a stream is:

```
maprcli stream upstream list -path <stream path>
```

For complete reference information, see [stream upstream list](#) on page 2730.

Removing Upstream Sources for a Stream

Explains how to un-register a stream as an upstream source for a stream using either the Control System or the CLI.

About this task

When you remove a stream as an upstream source for a stream, the upstream source stream will stop sending updates to the stream.

Removing Upstream Sources for a Stream Using the Control System

Procedure

1. Log in to the Control System and go the **Replication** tab in the [stream information page](#).
2. Select the upstream sources to remove in the **Upstream Sources** pane and click **Remove Upstream Source(s)**.
The **Remove Upstream Source(s)** confirmation window displays.
3. Verify the list and click **Remove Upstream Source**.
This action un-registers the selected stream(s) as upstream source(s) for this stream.

Removing Upstream Sources for a Stream Using the CLI or REST API

About this task

The command to decouple upstream sources is:

```
maprcli stream upstream remove -path <stream path> -upstream <upstream stream path>
```

For complete reference information, see [stream upstream remove](#) on page 2731.

Preparing Clusters for Log Compaction

Describes how to prepare your environment so you can use log compaction.

Installing with the Data Fabric Installer

When you use the Data Fabric Installer to install HPE Data Fabric Streams, a local gateway is also locally installed so that log compaction can be implemented. To configure for log compaction, see [maprcli stream create](#) on page 2708 and [stream edit](#) on page 2715.

Installing without the Data Fabric Installer

Other sections of the documentation describe the detailed steps for installing and configuring without the Data Fabric installer. Generally, you need to perform the following steps:

1. Install the Data Fabric software. To install Data Fabric without using the Data Fabric installer, follow the steps outlined at [Installing without the Installer](#) on page 229.
2. Install the Data Fabric gateway on your local cluster. Since gateways for log compaction are installed on the local cluster, no configuration is needed. See [Gateways and Stream Replication](#) on page 872 for general information about gateways.

Adding Gateways for Load Balancing

Since the number of gateways impacts the compaction process, you might want to increase the number of gateways on the cluster to improve the load distribution. To add gateways for log compaction, you install

additional Data Fabric gateways on your local cluster. See [Gateways and Stream Replication](#) on page 872 for general information about gateways.

NOTE: No configuration is required because the additional gateways are installed on the local cluster.

For More Information

See the following topics for more information:

- `maprccli stream create` on page 2708 and `stream edit` on page 2715
- [HPE Data Fabric Streams Java Applications](#) on page 3964, [HPE Data Fabric Streams Java API Library](#) on page 3967, and [Enabling Log Compaction](#) on page 3976

Mirroring Topics with Apache Kafka MirrorMaker

Use the Apache Kafka MirrorMaker utility either to mirror topics that are in Apache Kafka clusters to streams that are in HPE Data Fabric clusters or to Mirror topics that are in HPE Data Fabric clusters to Apache Kafka clusters.

Mirroring is a type of replication that takes place in this sequence of steps:

1. Messages that are published to topics in a source cluster are read by consumers that MirrorMaker manages.
2. These consumers send the messages to producers that MirrorMaker also manages.
3. The producers publish the messages in topics that are in the destination cluster.

Mirroring can continue indefinitely. Alternatively, you can mirror your data as a way of migrating it from Apache Kafka to HPE Data Fabric Streams. If you use it for this purpose, you can stop mirroring after migrating your producers and consumers to use HPE Data Fabric Streams, as described in [Migrating Apache Kafka 0.9.0 Applications to HPE Data Fabric Streams](#).

ATTENTION: MirrorMaker does not provide the same reliability guarantees as the replication features in HPE Data Fabric Streams. In particular, MirrorMaker does not replicate cursors or message positions, which makes disaster recovery much more difficult than with replication of HPE Data Fabric Streams. Therefore, HPE Data Fabric recommends MirrorMaker for use only for mirroring between HPE Data Fabric Streams and Apache Kafka, not for replication of HPE Data Fabric Streams.

Prerequisites

- Ensure that the destination stream in the HPE Data Fabric cluster exists. To create a stream, run the command `maprccli stream create`.
- Ensure that the ID of the user that runs MirrorMaker has the `produceperm` and `topicperm` permissions on the stream.

Command Syntax and Descriptions of Parameters

```
bin/kafka-mirror-maker.sh
--consumer.config <File that lists consumer properties and values>
--num.streams <Number of consumer threads>
--producer.config <File that lists producer properties and values>
--whitelist=<Java-style regular expression for specifying the topics to mirror>
```

Parameter	Description
<code>consumer.config</code>	The path and name of the file that lists the consumer properties. See the Consumer Properties and Descriptions on page 1777 section for detailed information.
<code>num.streams</code>	Use the <code>--num.streams</code> option to specify the number of mirror consumer threads to create. Note that if you start multiple mirror maker processes then you may want to look at the distribution of partitions on the source cluster. If the number of consumption streams is too high per mirror maker process, then some of the mirroring threads will be idle by virtue of the consumer rebalancing algorithm (if they do not end up owning any partitions for consumption).
<code>producer.config</code>	The path and name of the file that lists the producer properties. See the Producer Properties and Descriptions on page 1777 section for detailed information.
<code>whitelist</code>	A Java-style regular expression for specifying the topics to copy. Commas (',') are interpreted as the regex-choice symbol (' '). This parameter is required.

Consumer Properties and Descriptions

```
group.id=<ID>
bootstrap.servers=<IP address>:<port>
shallow.iterator.enable=false
```

Property	Description
<code>group.id</code>	A unique string that identifies the consumer group this consumer belongs to. This property is required if the consumer uses either the group management functionality by using <code>subscribe(topic)</code> or the Kafka-based offset management strategy. If <code>group.id</code> is not set and the value of the <code>num.streams</code> option is <code>> 1</code> , messages might go multiple times to a stream.
<code>bootstrap.servers</code>	A list of host/port pairs to use for establishing the initial connection to the Kafka cluster. The client will make use of all servers irrespective of which servers are specified here for bootstrapping—this list only impacts the initial hosts used to discover the full set of servers. This list should be in the form <code>host1:port1, host2:port2, . . .</code> . Since these servers are just used for the initial connection to discover the full cluster membership (which may change dynamically), this list need not contain the full set of servers (you may want more than one, though, in case a server is down).
<code>shallow.iterator.enable</code>	Set this value to <code>false</code> .

Producer Properties and Descriptions

```
key.serializer=<serializer class>
value.serializer=<serializer class>
```

```
streams.producer.default.stream=<Path and name of the stream to copy the
topics to>
auto.create.topics.enable=true
```

Property	Description
key.serializer	The name of the appropriate serialization class in the org.apache.kafka.common.serialization package or a class that implements the Serializer interface for serializing keys.
value.serializer	The class that implements the Serializer interface for serializing values.
streams.producer.default.stream	Specifies the path and name of stream that the topics will be copied to.
auto.create.topics.enable	Enables auto-creation of topics within the stream specified with the <code>streams.producer.default.stream</code> parameter.

Mirroring Topics from an Apache Kafka Cluster to the HPE Cluster

You can use MirrorMaker to mirror data continuously from Apache Kafka clusters to streams in HPE Data Fabric Streams clusters.

Prerequisites

- Because this procedure requires that MirrorMaker be run from the HPE Data Fabric cluster, ensure that the `mapr-kafka` package is installed on the node that you choose to run MirrorMaker from.
- Configure the node as a `mapr` client.
- Ensure that the ID of the user that runs MirrorMaker has the `produceperm` and `topicperm` permissions on the destination stream.

About this task

Alternatively, you can stop mirroring after you migrate the consumers and producers for your applications from your Apache Kafka cluster to your Data Fabric cluster where the stream is located. See in [Migrating Apache Kafka 0.9.0 Applications to HPE Data Fabric Streams](#) for details. After you start MirrorMaker, it launches a configurable number of consumer threads to read topics that are in a Kafka cluster and a number of producers to write the messages from those topics into topics in HPE Data Fabric Streams.

Figure 22: Mirroring from Apache Kafka to HPE Data Fabric Streams

Before running MirrorMaker, you create a file that contains the required configuration parameters for the consumers that read from the Apache Kafka cluster. You also create a file that contains the required configuration parameters for the producers that publish to the stream in the HPE Data Fabric cluster. You point to these files in the MirrorMaker command.

To specify which topics you want to mirror, use the `whitelist` parameter to provide a Java-style regular expression that matches the names of the topics that you want mirrored.

Procedure

1. Create a file that contains the required properties and values for consumers to use. When you run MirrorMaker, you point to this file by using the `consumer.config` parameter.

The descriptions of these properties, except for the last, are taken from the documentation for Apache Kafka. The last property is not documented.

Property	Description
<code>group.id</code>	A unique string that identifies the consumer group the consumers started by MirrorMaker belong to.
<code>bootstrap.servers</code>	A list of host/port pairs to use for establishing the initial connection to the Kafka cluster. The client will make use of all servers irrespective of which servers are specified here for bootstrapping—this list only impacts the initial hosts used to discover the full set of servers. This list should be in the form <code>host1:port1,host2:port2,...</code> Since these servers are just used for the initial connection to discover the full cluster membership (which may change dynamically), this list need not contain the full set of servers (you may want more than one, though, in case a server is down).

2. Create a file that contains the required properties and values for producers to use. When you run MirrorMaker, you point to this file by using the `producer.config` parameter.

Property	Description
<code>streams.producer.default.stream</code>	Specifies the path and name of the stream in the HPE Data Fabric cluster that the topics will be mirrored to.
<code>auto.create.topics.enable</code>	Set the value to <code>true</code> . The producers will therefore be able to create topics in the destination stream automatically.

3. Run MirrorMaker with this command to start mirroring topics from Apache Kafka to HPE Data Fabric Streams:

Syntax

```
/opt/mapr/kafka/kafka-0.9.0/bin/kafka-mirror-maker.sh
--consumer.config <File that lists consumer properties and values>
--num.streams <Number of consumer threads>
--producer.config <File that lists producer properties and values>
--whitelist=<Java-style regular expression for specifying the topics to mirror>
```

Parameter	Description
<code>consumer.config</code>	The path and name of the file that lists the consumer properties and their values.

Parameter	Description
<code>num.streams</code>	Use this option to specify the number of mirror consumer threads to create. Note that if you start multiple mirror maker processes then you may want to look at the distribution of partitions on the source cluster. If the number of consumption streams is too high per mirror maker process, then some of the mirroring threads will be idle by virtue of the consumer rebalancing algorithm (if they do not end up owning any partitions for consumption).
<code>producer.config</code>	The path and name of the file that lists the producer properties and their values.
<code>whitelist</code>	A Java-style regular expression for specifying the topics to copy. Commas (',') are interpreted as the regex-choice symbol (' '). This parameter is required.

Example

In this example, the file that lists the properties and values for the consumers that will read messages from the topics in Apache Kafka is named `consumers.props`. It contains this list:

```
group.id=cg1
bootstrap.servers=10.10.100.87:9093
shallow.iterator.enable=false
```

The file that lists the properties and values for the producers that will publish messages to topics in HPE Data Fabric Streams is named `producers.props`. It contains this list:

```
streams.producer.default.stream=/newStream
auto.create.topics.enable=true
```

The topics to mirror all have names that begin with `na_west`. When running the command, we can use `"na_west.*"` as the regular expression to use for the `whitelist` parameter.

Here is the command:

```
bin/kafka-mirror-maker.sh --consumer.config consumers.props
--num.streams 2 --producer.config producers.props --whitelist="na_west.*"
```

Mirroring Topics from the HPE Cluster to an Apache Kafka Cluster

You can use MirrorMaker to mirror data continuously from streams in HPE Data Fabric clusters to Apache Kafka clusters.

Prerequisites

- This procedure requires MirrorMaker to run from the HPE Data Fabric cluster. Verify that the `mapr-kafka` package is installed on the node that you choose to run MirrorMaker on.
- Configure the node as a `mapr` client.
- Ensure that the ID of the user who runs MirrorMaker has the `consumeperm` permission on the stream.

About this task

After you start MirrorMaker, it launches a configurable number of consumer threads to read topics that are in a stream in a HPE Data Fabric cluster and a number of producers to write the messages from those topics into topics in an Apache Kafka cluster.

Figure 23: Mirroring from HPE Data Fabric Streams to Apache Kafka

Before running MirrorMaker, you create a file that contains the required configuration parameters for the consumers that read from the stream in the HPE Data Fabric cluster. You also create a file that contains the required configuration parameters for the producers that publish to the Apache Kafka cluster. You point to these files in the MirrorMaker command.

To specify which topics you want to mirror, use the `whitelist` parameter to provide a Java-style regular expression that matches the names of the topics that you want mirrored.

Procedure

1. Create a file that contains the required properties and values for consumers to use. When you run MirrorMaker, you point to this file by using the `consumer.config` parameter.

Property	Description
<code>streams.record.strip.streampath</code>	Set the value of this property to true. In messages that are written to streams, the names of topics include the paths and names of the streams in which those topics are located. Apache Kafka needs only the names of the topics. This parameter removes the path and name of the stream that the topics will be mirrored from.
<code>streams.consumer.default.stream</code>	Specifies the path and name of the stream that the topics will be mirrored from.
<code>group.id</code>	A unique string that identifies the consumer group the consumers started by MirrorMaker belong to.

2. Create a file that contains the required properties and values for producers to use. When you run MirrorMaker, you point to this file by using the `producer.config` parameter.

Property	Description
<code>bootstrap.servers</code>	A list of host/port pairs to use for establishing the initial connection to the Kafka cluster. The producers will make use of all servers irrespective of which servers are specified here for bootstrapping—this list only impacts the initial hosts used to discover the full set of servers. This list should be in the form <code>host1:port1,host2:port2,...</code> . Since these servers are just used for the initial connection to discover the full cluster membership (which may change dynamically), this list need not contain the full set of servers (you may want more than one, though, in case a server is down).
<code>producer.type</code>	Specifies whether the messages are published asynchronously in batches or as data is received by producers. The values are <code>async</code> and <code>sync</code> .
<code>compression.codec</code>	Specifies the compression codec for all messages that are generated by producers. The possible values are <code>none</code> , <code>gzip</code> , <code>snappy</code> , and <code>lz4</code> .

3. Run MirrorMaker with this command to start mirroring topics from HPE Data Fabric Streams to Apache Kafka:

Syntax

```
bin/kafka-mirror-maker.sh
--consumer.config <File that lists consumer properties and values>
--num.streams <Number of consumer threads>
--producer.config <File that lists producer properties and values>
--whitelist=<Java-style regular expression for specifying the topics to mirror>
```

Parameter	Description
<code>consumer.config</code>	The path and name of the file that lists the consumer properties and their values.
<code>new.consumer</code>	Specifies to use consumers that use the Apache Kafka 0.90 API library.
<code>num.streams</code>	Use this parameter to specify the number of mirror consumer threads to create. Note that if you start multiple mirror maker processes then you may want to look at the distribution of partitions on the source cluster. If the number of consumption streams is too high per mirror maker process, then some of the mirroring threads will be idle by virtue of the consumer rebalancing algorithm (if they do not end up owning any partitions for consumption).
<code>producer.config</code>	The path and name of the file that lists the producer properties and their values.
<code>whitelist</code>	A Java-style regular expression for specifying the topics to copy. Commas (',') are interpreted as the regex-choice symbol (' '). This parameter is required.

Example

In this example, the file that lists the properties and values for the consumer that will read messages from the topics in HPE Data Fabric Streams is named `consumers.props`. It contains this list:

```
streams.record.strip.streampath=true
streams.consumer.default.stream=/myStream
group.id=cg1
```

The file that lists the properties and values for the producers that will publish messages to topics in Apache Kafka is named `producers.props`. It contains this list:

```
bootstrap.servers =10.10.83.93:9092
producer.type=sync
compression.codec=none
```

The topics to mirror all have names that begin with `na_west`. When running the command, we can use `"na_west.*"` as the regular expression to use for the whitelist parameter.

```
bin/kafka-mirror-maker.sh --new.consumer
--consumer.config consumers.props --num.streams 2 --producer.config
producers.props
--whitelist="na_west.*"
```

Mirroring Topics with HPE Data Fabric MirrorMaker 2

MirrorMaker 2.0 is a multi-cluster, cross-data-center replication engine based on the Kafka Connect framework. MirrorMaker 2 is available starting in EEP 8.0.0.

Mirror Maker 2.0 replicates data in topics from one Kafka cluster to another. HPE Data Fabric Mirror Maker 2 can mirror data:

- from Apache Kafka clusters to Apache Kafka clusters.
- from Apache Kafka clusters to streams in HPE Data Fabric clusters.
- from streams in HPE Data Fabric clusters to Apache Kafka clusters.
- between streams in HPE Data Fabric clusters.

MirrorMaker 2 Architecture

MirrorMaker 2 uses the Kafka Connect framework to simplify configuration and scaling. Both source and sink connectors are provided to enable complex flows between multiple Kafka clusters and across data centers via existing Kafka Connect clusters. The main MirrorMaker 2 components are actually Kafka connectors, as described in the following list:

- The `MirrorSourceConnector` replicates records from local to remote clusters and enables offset synchronization.
- The `MirrorCheckpointConnector` manages consumer offset synchronization, emits checkpoints, and enables failover.
- The `MirrorHeartbeatConnector` provides heartbeats, monitoring of replication flows, and client discovery of replication topologies, which can be more complex than for the original MirrorMaker.

As shown in the following MirrorMaker 2 architecture diagram, the source and sink connectors contain a pair of producers and consumers to replicate records, and a pair of `AdminClients` to propagate configuration changes:

Prerequisites

When using HPE Data Fabric streams as the source or target:

- Ensure that the destination stream in the HPE Data Fabric cluster exists. To create a stream, run the `maprcli stream create` command.
- Ensure that the ID of the user that runs MirrorMaker 2 has the `produceperm` and `topicperm` permissions on the stream.

When using an Apache Kafka cluster as the source or target:

- Verify that a connection to the Apache Kafka cluster exists.

Connector Configuration Properties for MirrorMaker 2

Use the `.stream` property instead of the `.bootstrap.servers` property when an HPE Data Fabric stream is the source or the target.

The following table lists the properties common to the SourceConnectors and SinkConnector:

Property	Default	Description
name	required	name of the connector, e.g. "us-west->us-east"
topics	empty string	regex of topics to replicate, e.g. "topic1 topic2 topic3". Comma-separated lists are also supported.
topics.blacklist	".*\.\internal, .*\.replica, __consumer_offsets" or similar	topics to exclude from replication
groups	empty string	regex of groups to replicate, e.g. ".*"

Property	Default	Description
groups.blacklist	empty string	groups to exclude from replication
source.cluster.alias	required	name of the cluster being replicated
target.cluster.alias	required	name of the downstream Kafka cluster
source.cluster.stream	required or can be replaced by bootstrap.servers	stream from upstream HPE Data Fabric cluster to replicate
target.cluster.stream	required or can be replaced by bootstrap.servers	Stream from downstream HPE Data Fabric cluster
source.cluster.bootstrap.servers	required or can be replaced by stream	upstream cluster to replicate
target.cluster.bootstrap.servers	required or can be replaced by stream	downstream cluster
sync.topic.configs.enabled	true	whether or not to monitor source cluster for configuration changes
sync.topic.acls.enabled	true	whether to monitor source cluster ACLs for changes
emit.heartbeats.enabled	true	connector should periodically emit heartbeats
emit.heartbeats.interval.seconds	5 (seconds)	frequency of heartbeats
emit.checkpoints.enabled	true	connector should periodically emit consumer offset information
emit.checkpoints.interval.seconds	5 (seconds)	frequency of checkpoints
refresh.topics.enabled	true	connector should periodically check for new topics
refresh.topics.interval.seconds	5 (seconds)	frequency to check source cluster for new topics
refresh.groups.enabled	true	connector should periodically check for new consumer groups
refresh.groups.interval.seconds	5 (seconds)	frequency to check source cluster for new consumer groups
readahead.queue.capacity	500 (records)	number of records to let consumer get ahead of producer
replication.policy.class	org.apache.kafka.connect.mirror.DefaultReplicationPolicy	use LegacyReplicationPolicy to mimic legacy MirrorMaker
heartbeats.topic.retention.ms	1 day	used when creating heartbeat topics for the first time
checkpoints.topic.retention.ms	1 day	used when creating checkpoint topics for the first time
offset.syncs.topic.retention.ms	max long	used when creating offset sync topic for the first time
replication.factor	2	used when creating remote topics

The following table lists internal client properties that you can override:

Property	Description
source.cluster.consumer.*	overrides for the source-cluster consumer

Property	Description
source.cluster.producer.*	overrides for the source-cluster producer
source.cluster.admin.*	overrides for the source-cluster admin
target.cluster.consumer.*	overrides for the target-cluster consumer
target.cluster.producer.*	overrides for the target-cluster producer
target.cluster.admin.*	overrides for the target-cluster admin

Example Configuration File

The following `mm2.properties` configuration file example shows the configuration for an HPE Data Fabric stream to Apache Kafka cluster workflow.

```
# Datacenters.
clusters = source, target
source.stream = /str
target.bootstrap.servers = 192.168.33.12:9092

# Source and target cluster configurations.
source.config.storage.replication.factor = 1
target.config.storage.replication.factor = 1

source.offset.storage.replication.factor = 1
target.offset.storage.replication.factor = 1

source.status.storage.replication.factor = 1
target.status.storage.replication.factor = 1

source->target.enabled = true
target->source.enabled = false

# Mirror maker configurations.
offset-syncs.topic.replication.factor = 1
heartbeats.topic.replication.factor = 1
checkpoints.topic.replication.factor = 1

topics = .*
groups = .*

tasks.max = 1
replication.factor = 1
refresh.topics.enabled = true
sync.topic.configs.enabled = true
refresh.topics.interval.seconds = 30

topics.blacklist = .*[\-\.]internal, .*\.replica, __consumer_offsets
groups.blacklist = console-consumer-.*, connect-.*, __.*

# Enable heartbeats and checkpoints.
source->target.emit.heartbeats.enabled = true
source->target.emit.checkpoints.enabled = true
```

Command Syntax

To start the MirrorMaker 2 connectors, run the following command:

```
/opt/mapr/kafka/kafka-<version>/bin/connect-mirror-maker.sh mm2.properties
```

Logs are written to the console instead of log files. You can change where logs are written by editing the `/opt/mapr/kafka/kafka-<version>/config/connect-mirror-maker-log4j.properties` file.

Limitations

There are several limitations that differentiate HPE Data Fabric MirrorMaker 2 from Apache Kafka MirrorMaker 2:

- MirrorCheckpointConnector is not supported by HPE Data Fabric MirrorMaker 2; therefore, mirroring is based only on MirrorSourceConnector and MirrorHeartbeatConnector.
- Access Control Lists (ACLs) synchronization is not supported because HPE Data Fabric Streams are not supported ACL.
- Broker configurations that include any of the `log.*` properties are not synchronized. For example, if the broker configuration contains the `log.dir` property, the broker configuration is not synchronized across all brokers in the cluster.

Administering Data Fabric Gateways

A HPE Data Fabric gateway mediates one-way communication between a source HPE Data Fabric cluster and a destination cluster. You can replicate HPE Data Fabric Database tables (binary and JSON) and HPE Data Fabric Streams streams. HPE Data Fabric gateways also apply updates from JSON tables to their secondary indexes and propagate Change Data Capture (CDC) logs.

The initial task for setting up your gateways is to decide where you want to put them:

- If you are going to replicate HPE Data Fabric Database tables, see [Gateways for Replicating HPE Data Fabric Database Tables](#) on page 831.
- If you are going to replicate streams, see [Gateways and Stream Replication](#) on page 872.
- If your HPE Data Fabric Database JSON tables have secondary indexes, see [Preparing Clusters for Querying using Secondary Indexes on JSON Tables](#) on page 1719.
- If you are using CDC, see [Getting Started with CDC](#) on page 810.

NOTE: Gateways perform negligible disk I/O and use negligible amounts of memory, though gateways require significant CPU usage.

However, the resource that gateways use the most is network bytes. For example, if the peak network throughput for puts is about 40 MB per second per node, in a 10-node source cluster the peak network throughput will be about 400 MB per second. So, the aggregate network throughput required on the nodes running gateways will be 400 MB per second for both incoming and outgoing traffic. The aggregate network throughput for a 50 node cluster would be 2GB per second.

For another example, in the following diagram there are two source clusters of three nodes each and the clusters are replicating to one destination cluster. The peak traffic on the gateways will be 40MB per second per cluster node, which means that these gateways together will experience a peak network load of 240MB per second.

Although the load is balanced across the two gateways, so that each gateway experiences a peak network load of 120MB per second, each gateway should be able to tolerate the full aggregate network load in case the other gateway fails unexpectedly.

Configuring Gateways for Table and Stream Replication

Configuring gateways involves installing the `mapr-gateway` package on nodes on a Data Fabric destination cluster and then configuring the Data Fabric source cluster to communicate with the destination cluster. The Data Fabric source cluster is configured by specifying the destination cluster's CLDB node and gateway nodes.

How Many Gateways to Configure?

Although it is possible to use a single gateway, the recommended practice is to configure at least two (2) gateways, so that replication can continue if one gateway fails. Data Fabric source clusters distribute requests among the gateways in a round-robin fashion. See [Gateways for Replicating HPE Data Fabric Database Tables](#) on page 831, [Table Replication](#) on page 820, and [Preparing Clusters for Stream Replication](#) on page 1763 for more information about replication.

For more information about setting up cross-cluster security, including cross-cluster security for table and stream replication, see [Setting Up Cross-Cluster Security](#) on page 2222.

Default Gateway Configuration for Replication

If you do not perform any of these options, HPE Data Fabric Database uses the configuration from the `mapr-clusters.conf` file. It uses the cluster name specified in that file as the destination cluster, and the CLDB node addresses as the gateway nodes. You must have gateways running on these CLDB nodes.

Configuration Procedure

TIP: To list the current gateways, see [cluster gateway get](#) on page 2326.

1. On the destination cluster, install the `mapr-gateway` package on each node where you want to run a gateway. See [Step 4: Install Cluster Service Packages](#) on page 244.

NOTE: On the gateway nodes in the destination cluster, when you run (or re-run) the `configure.sh` script (in addition to your regular parameters) be sure to specify the `-N` parameter with the name of the cluster to which the gateway belongs. For more information about `configure.sh` usage, options, and examples, see [configure.sh](#) on page 3186.

2. To change the port that a gateway uses (by default, gateways use port 7660):

- a. On the node where the gateway is running, edit the `/opt/mapr/conf/gateway.conf` file, ensure that the line `#gateway.port=7660` is not commented, and change the port number. For more information about `gateway.conf` configuration properties, see [gateway.conf](#) on page 3367.
 - b. After saving the file, restart the gateway by running this command: `maprccli node services -name gateway -action restart`
3. On the source cluster, specify the destination cluster's name and gateway nodes by using one of the following methods:
 - Run the `maprccli cluster gateway set` command:

```
maprccli cluster gateway set -dstcluster <cluster name> -gateways
"<space-delimited list of gateways>"
```

The following sample command sets two gateway nodes on the destination cluster `my.cluster.com`:

```
maprccli cluster gateway set -dstcluster my.cluster.com -gateways
"node1.com node2.com"
```

- Add a DNS record to your DNS server's zone file for your domain.

See [Managing Gateways](#) on page 1791 for more information about using these methods.

Describes the commands for listing gateways, checking status of gateways, managing gateways if they fail, and troubleshooting gateways.

Managing Gateways

Describes the commands for listing gateways, checking status of gateways, managing gateways if they fail, and troubleshooting gateways.

You can run the following commands to perform operations on your gateways.

NOTE: If you have configured an intra-cluster gateway, the source and destination clusters are the same.

- To see a list of the gateways for a particular destination cluster:

Run the [maprccli cluster gateway get](#) command on the source cluster. Specify the name of the destination cluster with the `-dstcluster` parameter. If you run the command remotely from your source cluster, specify the name of the source cluster with the `-cluster` parameter.

- To see a list of the gateways for all of the destination clusters to which the source cluster is replicating:

Run the [maprccli cluster gateway list](#) command on the source cluster. If you run the command remotely from your source cluster, specify the name of the source cluster with the `-cluster` parameter.

- To remove the list of gateways that you specified for a destination cluster by using the `maprccli cluster gateway set` command:

Run the [maprccli cluster gateway delete](#) command on the source cluster. Specify the name of the destination cluster with the `-dstcluster` parameter. If you run the command remotely from your source cluster, specify the name of the source cluster with the `-cluster` parameter.

- To find out how HPE Data Fabric Database or HPE Data Fabric Streams is finding gateways (for example, from DNS records, lists created by the `maprccli cluster gateway set` command or the `mapr-clusters.conf` file):

Run the command [maprccli cluster gateway resolve](#) on the source cluster. Specify the name of the destination cluster with the `-dstcluster` parameter. If you run the command remotely from your source cluster, specify the name of the source cluster with the `-cluster` parameter.

- To stop and start one or more gateways:

Run the `maprccli node services -name gateway -action stop|start` on the clusters where the gateways are running.

```
/opt/mapr/bin/maprccli node services -name gateway -action stop -nodes
<hostnames or IP addresses separated by spaces>
```

```
/opt/mapr/bin/maprccli node services -name gateway -action start -nodes
<hostnames or IP addresses separated by spaces>
```

- To check the status of a gateway service on a particular node:

Run the command [maprccli service list](#) on the clusters where the gateways are running.

Running the `maprcli cluster gateway set` command

The syntax of the `maprcli cluster gateway set` command is:

```
/opt/mapr/bin/maprcli cluster gateway set -dstcluster <cluster name> -gateways "<space-delimited list of gateways>"
```

To generate a list of the existing gateways in a Data Fabric cluster, use the `maprcli cluster gateway list` command. You can then copy this list and paste it into the `maprcli cluster gateway set` command. Alternatively, to generate a list of the gateways on a local cluster, run the `maprcli cluster gateway local -format text` command. If you want to run the command from a different cluster and point to the cluster where the gateways are located, use the `-cluster` parameter to provide the name of that cluster.

For example, suppose that you are configuring table replication from the cluster `sanfrancisco` to the cluster `newyork`, and want to use two gateways. The nodes on which these gateways are located are named `gw1` and `gw2`.

The command that you run will be as follows:

```
/opt/mapr/bin/maprcli cluster gateway set -dstcluster newyork -gateways "gw1.bigcompany.com gw2.bigcompany.com"
```

Adding a DNS record to your DNS server's zone file for your domain

In your DNS server's zone file for your domain, you can add a record for the cluster where gateways are located, listing the nodes to use as gateways. You can use the Control System to create a record that you can copy into a DNS configuration file, run a `maprcli` command to generate the record, or create a record manually.

For details, see [Specifying the Location of Gateways](#) on page 1345.

If a Gateway Fails

If a gateway fails, the warden service tries three (3) times to restart it automatically. After an interval, the warden tries again three times to start the gateway. You can configure the interval by using the parameter `services.retryinterval.time.sec` in the `warden.conf` file. The default is 30 minutes.

During the time that the gateway is down, source clusters will resend updates to other gateways. Source clusters will also ping the failed gateway with an exponentially increasing backoff.

If all of the gateways fail in a destination cluster, source clusters will ping the failed gateways in the same manner. Updates pending replication are stored on disk in an internal data structure until at least one gateway in the destination cluster comes back online. Therefore, you will see additional storage costs during a gateway outage. The Gateway Service Down alarm in the Control System will notify you when none of the gateways in a destination cluster can be reached.

If the additional storage becomes too costly, you can follow either of these procedures:

If you are replicating to a HPE Data Fabric Database binary table:

1. Run the `maprcli table replica remove` command to stop replicating to the replica. This action deletes the pending updates.
2. Resolve the gateway outage.
3. Recreate the replica and start replicating to it by running the `maprcli table replica autosetup` command.

If you are replicating to a HPE Data Fabric Streams stream:

1. Run the `maprcli stream replica remove` command to stop replicating to the replica stream. This action cancels the pending updates to the replica stream.
2. Resolve the gateway outage.
3. Run the command `maprcli stream replica autsetup` to recreate the replica stream and start replicating to it.

Troubleshooting

You can refer to two log files for each gateway when troubleshooting. Both these files are in the `/opt/mapr/logs` directory on the node where the gateway is running:

- `gateway.log`
- `gatewayinit.log`

HPE Data Fabric Database Lookup Order

HPE Data Fabric Database uses the following order to locate the gateways that are running in a destination cluster.

- Look up the destination cluster's name and gateway addresses in the information specified by the `maprcli cluster gateway set` command. If a list of gateways, then a DNS lookup is performed.
- Perform a DNS lookup of the destination cluster and the addresses of the gateways. If no DNS record for the destination cluster is found, then the lookup goes to the `mapr-clusters.conf` file.
- Look up the destination cluster's name and the CLDB node addresses in the `mapr-clusters.conf` file under the assumption that gateways are running on all of the CLDB nodes and only on those nodes.

Administering Services

The various topics in this section describe how to manage (start, stop, restart, etc.) the various services installed on the Data Fabric cluster using the Control System (click **Services**) and the CLI.

Managing Services

Synopsis on managing services.

Once a role is installed on a node and the warden has been restarted, HPE Data Fabric recognizes the role for that node. You can then start the service. Refer to the following topics for information on managing services on a node using the Control System and the CLI.

Viewing the List of Services

Explains how to view the list of services using either the Control System or the CLI.

Viewing the Services Installed on the Cluster Using the Control System

Procedure

- Log in to the Control System and click **Services**.

The **Services** pane displays all the services installed on the cluster. On the non-Kubernetes version of the Control System, the pane displays the following:

Column Name	Column Description
Service	The name of the installed service.
Running Nodes	The number of nodes on which the associated service is running. The service can be stopped (■) or restarted (↺). Click the number in this column to view the nodes on which the service is running.
Standby Nodes	The number of nodes on which the associated service is in standby (available, but not running) state. The service can be started (▶) or restarted (↺). Click the number in this column to view the nodes on which the service is in standby state.
Failed Nodes	The number of nodes on which the service has failed. The service can be started (▶) or restarted (↺). Click the number in this column to view the nodes on which the service has failed.

Column Name	Column Description
Stopped Nodes	The number of nodes on which the associated service is stopped (and not running). The service can be started (▶) or restarted (↺). Click the number in this column to view the nodes on which the service has been stopped.
Log Viewer	(Displays only if Kibana is installed on a node) The link (🔗) to the Kibana UI.

You can filter the list of services displayed by:

- **EEP**, which includes services such as Hive, Drill, etc.
- **Core**, which includes services such as CLDB, Hoststats, File server, etc.
- **Monitoring**, which includes services such as Grafana, Kibana, etc.

Viewing the Services Running on a Node Using the Control System

Procedure

1. Log in to the Control System and click **Nodes**.

NOTE: The **Nodes** menu is not available in the Kubernetes version of the Control System.

2. You can:

- Hover the cursor over the number listed in the **Running Services** column in the **Nodes** pane to view the list of services installed on that node.
- Go to the **Summary** tab in the [node information page](#) to view detailed information on the services installed on a node.

In the **Summary** tab, for each service running on the node, the **Services** pane displays the following:

Column Name	Column Description
Service	The name of the service.
State	The current state of the service. Value can be: <ul style="list-style-type: none"> • Running • Stopped
Memory Allocated	The amount of system memory allocated to the service.
System Memory Utilized	The percentage of memory utilized by the service.
CPU Usage	The CPU used by the service.
Log Path	The path to the service log file.
Log Viewer	The link to the Kibana UI (only if Kibana is installed).

You can select the checkbox beside one or more services to take the following actions:

- [Start Services](#)
- [Stop Services](#)
- [Restart Services](#)

NOTE: If Kibana is installed, you can click  to view the logs. See [Kibana User Guide](#) for more information.

Retrieving the Services Running on a Node Using the CLI or REST API

About this task

The command to list all the services on a node is:

```
maprcli service list -node <node name>
```

For complete reference information, see [service list](#) on page 2695.

Enabling and Disabling a Service Using the CLI and REST API

Describes how to enable or disable a service using either the REST API or the CLI.

About this task

You can disable a service to prevent it from starting or restarting when Warden starts or restarts, and enable a service to allow it to start or restart when Warden starts or restarts.

Disabling a Service Using the CLI or REST API

About this task

CLI

Run the following command:

```
maprcli node
services -nodes <hostName> -name
<serviceName> -action disable
```

REST

Send a request of type POST. For example:

```
curl -X POST 'https://
<host>:8443/rest/node/services?
nodes=<hostName>&name=<serviceName>
&action=disable' --user
<username>:<password>
```

NOTE: When you disable a service, the service is stopped and the service is not automatically started/restarted when Warden is started/restarted.

See [node services](#) on page 2598 for more information.

Enabling a Service Using the CLI or REST API

About this task

CLI

Run the following command:

```
maprcli node
services -nodes <hostName> -name
<serviceName> -action enable
```

REST

Send a request of type POST. For example:

```
curl -X POST 'https://
<host>:8443/rest/node/services?
```

```
nodes=<hostName>&name=<serviceName>
&action=enable' --user
<username>:<password>
```

 **NOTE:** When you enable a service, the service is started/restarted when Warden is started/restarted.

See [node services](#) on page 2598 for more information.

Related tasks

[Restarting the Services](#) on page 1402

Describes how to restart a service using either the Control System, the CLI or the REST API.

Starting the Services

Explains how to start services using either the Control System, the CLI or the REST API.

About this task

You can start one or more services using the Control System or the CLI if the service is not disabled. If the service is disabled, you must enable the service first, in order to start the service. See [Enabling and Disabling a Service Using the CLI and REST API](#) on page 1399 for more information.

Starting the Services Running on the Nodes Using the Control System

About this task

To start the services running on the nodes:

Procedure

1. Log in to the Control System and click **Nodes** to display the **Nodes** page.

NOTE: The **Nodes** page is not available on the Kubernetes version of the Control System.

2. Select the nodes from the list of nodes in the **Nodes** pane and click **Manage Services** to display the **Manage Services** window.
3. Choose the **Start** radio button for the services you wish to start on the selected nodes and click **Save**.

Starting the Services Running on a Node Using the Control System

About this task

To start one or more services running on a node:

Procedure

1. Go to the **Summary** tab in the [node information page](#).
2. Select the services to start in the **Services** pane.
3. Click **Start Services**.
The **Start Services** confirmation dialog displays.
4. Verify the list of services to start and click **Start Service**.

Starting the Services on the Cluster Using the Control System

Procedure

1. Log in to the Control System and click **Services** to display the list of services on the cluster.
2. On the non-Kubernetes version of the Control System, click  for the service to start. The **Start Service** confirmation dialog displays.
3. Verify the list of nodes on which to start the service and click **Start Service**.

Starting a Service Using the CLI or REST API

About this task

The basic command to start a service on a node is:

```
maprcli node services -nodes <node name> -name <service> -action start
```

For complete reference information, see [node services](#) on page 2598.

Stopping the Services

Describes how to stop services using either the Control System, the CLI or the REST API.

Stopping the Services Running on the Nodes Using the Control System

About this task

To stop the services running on the nodes:

Procedure

1. Log in to the Control System and click **Nodes** to display the **Nodes** page.
 **NOTE:** The **Nodes** page is not available in the Kubernetes version of the Control System.
2. Select the nodes from the list of nodes in the **Nodes** pane and click **Manage Services** to display the **Manage Services** window.
3. Choose the **Stop** radio button for the services you wish to stop on the selected nodes and click **Save**.

Stopping the Services on a Node Using the Control System

About this task

To stop one or more services running on a node:

Procedure

1. Go to the **Summary** tab in the [node information page](#).
2. Select the services to stop in the **Services** pane.
3. Click **Stop Services**.
The **Stop Services** confirmation dialog displays.
4. Verify the list of services to stop and click **Stop Service**.

Stopping a Service on the Cluster Using the Control System

Procedure

1. Log in to the Control System and click **Services**.
2. On the non-Kubernetes version, click  associated with the service to stop. The **Stop Service** confirmation dialog displays.
3. Verify the list of nodes on which to stop the service and click **Stop Service**.

Stopping the Services Using the CLI or REST API

About this task

The basic command to stop a service on a node is:

```
maprcli node services -nodes <node name> -name <service> -action stop
```

For complete reference information, see [node services](#) on page 2598.

Restarting the Services

Describes how to restart a service using either the Control System, the CLI or the REST API.

About this task

When a HPE Data Fabric system is rebooted, the following services are automatically restarted:

- mapr-warden
- mapr-zookeeper
- mapr-loopbacknfs
- mapr-posix-client-*

These services are also automatically restarted if they are shut down externally (as opposed to being shut down explicitly via `service` or `sysctl` commands).

NOTE: This feature is implemented with `systemd` and is only supported on the following operating systems:

- RHEL 7.0, 7.1
- CentOS 7.0, 7.1
- SLES 12

This feature is not supported on any of the Ubuntu versions that HPE Data Fabric currently supports.

You can restart one or more services using the Control System and the CLI if the services are not disabled. However, if a service is disabled, the service cannot be restarted. To restart a service, make sure the service is enabled. See [Enabling and Disabling a Service Using the CLI and REST API](#) on page 1796 for more information.

Restarting the Services Running on the Nodes Using the Control System

About this task

To restart the services running on the nodes:

Procedure

1. Log in to the Control System and click **Nodes** to display the **Nodes** page.

NOTE: The **Nodes** page is not available on the Kubernetes version of the Control System.

2. Select the nodes from the list of nodes in the **Nodes** pane and click **Manage Services** to display the **Manage Services** window.
3. Choose the **Restart** radio button for the services you wish to restart on the selected nodes and click **Save**.

Restarting one or more Services on a Node Using the Control System**Procedure**

1. Go to the **Summary** tab in the [node information page](#).
2. Select the services to restart in the **Services** pane.
3. Click **Restart Service(s)**.
The **Restart Service(s)** confirmation dialog displays.
4. Verify the list of services to restart and click **Restart Service**.

Restarting the Services on the Cluster Using the Control System**Procedure**

1. Log in to the Control System and navigate to **Services**.
2. On the non-Kubernetes version, click  associated with the service to restart.
The **Restart Service** confirmation dialog displays.
3. Verify the list of nodes on which to restart the service and click **Restart Service**.

Restarting a Service Using the CLI or REST API**About this task**

The basic command to restart a service on a node is:

```
maprcli node services -nodes <node name> -name <service> -action restart
```

For complete reference information, see [node services](#) on page 2598.

Related tasks

[Enabling and Disabling a Service Using the CLI and REST API](#) on page 1796
Describes how to enable or disable a service using either the REST API or the CLI.

Viewing a Service Information Page

Describes how to view the information pages for the installed services using the Control System.

About this task

Procedure

1. Log in to the Control System and click **Services**.

NOTE: The **Services** page is not available on the Kubernetes version of the Control System.

The **Services** pane displays the list of services that are installed on the cluster.

2. Click the name of the service from the list.

The information page for the service displays.

Changing the User for Data Fabric Services from the Command-Line

Explains how use the CLI to change the user that Data Fabric services run as.

About this task

All services should run with the same uid/gid on all nodes in the cluster.

Running Data Fabric Services as the Root User**Procedure**

1. Stop Warden.

```
service mapr-warden stop
```

2. If ZooKeeper is installed on the node, stop it.

```
service mapr-zookeeper stop
```

3. Run the script `$INSTALL_DIR/server/config-mapr-user.sh -u root`

4. If Zookeeper is installed, start it.

```
service mapr-zookeeper start
```

5. Start Warden.

```
service mapr-warden start
```

Running Data Fabric Services as a Non-Root User**Procedure**

1. Stop Warden.

```
service mapr-warden stop
```

2. If ZooKeeper is installed on the node, stop it.

```
service mapr-zookeeper stop
```

3. If the MAPR_USER does not exist, create the user/group with the same UID and GID.

4. If the MAPR_USER exists, verify that the uid of MAPR_USER is the same as the value on the CLDB node.
5. Run `$INSTALL_DIR/server/config-mapr-user.sh -u MAPR_USER`.
6. If Zookeeper is installed, start it.

```
service mapr-zookeeper start
```

7. Start Warden.

```
service mapr-warden start
```

8. After clearing `NODE_ALARM_MAPRUSER_MISMATCH` alarms on all nodes, run `$INSTALL_DIR/server/upgrade2mapruser.sh` on all nodes wherever the alarm is raised.

Viewing the Service Log

Explains how to view service logs using Kibana.

About this task

If Kibana is installed on the node, you can view the service log in the Kibana UI from the Control System. To view the log in the Kibana UI from the Control System:

Procedure

1. Log in to the Control System and do one of the following:
 - Click **Services** to display the list of services installed on the cluster.
 - Go to the **Summary** tab in the [service information page](#) for the service.
2. Click  in the **Log Viewer** column to view the log for the associated service in the Kibana UI. See [Kibana User Guide](#) for more information.

Viewing CLDB Information

Describes how to view CLDB information from the CLDB page, and provides an explanation of each field that the page displays.

The CLDB page on the Control Panel provides information about the Container Location Database (CLDB). The CLDB is a management service that tracks container locations and the root of volumes.

To display the CLDB information page, log in to the Control System and go to the [service information page](#) for CLDB. Alternatively, you can use the following links to access the CLDB page:

- For a *secure* cluster, access the CLDB view at `https://<cldbmaster>:7443/cldb.jsp`.
- For an *non-secure* cluster, access the CLDB view at `http://<cldbmaster>:7221/cldb.jsp`.

The CLDB page displays the following information:

Container Location Database

Description: This section displays:

- CLDB Mode: The CLDB node can be in one of the following modes: MASTER_READ_WRITE or SLAVE_READ_ONLY.

- CLDB BuildVersion: Lists the build version.
- Master for CLDB volume ready: Indicates whether the CLDB volume is ready for use.
- CLDB Status: The status of the CLDB node.
- Cluster Capacity: The storage capacity for the cluster.
- Cluster Used: The amount of storage in use.
- Cluster Available: The amount of available storage.
- Cluster Used Percentage: The percentage of storage in use.

Active FileServers

Description: Displays information about the File Servers in use:

- ServerID (Hex): The server's ID in hexadecimal notation.
- ServerId: The server's ID in decimal notation.
- HostPort: The IP address of the file server.
- HostName: The hostname assigned to the file server.
- Network Location: The network topology for the file server.
- Last Heartbeat (s) : The timestamp for the last received heartbeat.
- State: Is the file server ACTIVE (in use at present)
- Capacity (MB): Total storage capacity on the file server.
- Used (MB): Storage used on the file server.
- Available (MB): Storage available on the file server.
- In Transit (MB): Amount of data in transit

Active NFSServers

Description: Displays information about the NFS Servers in use:

- ServerID (Hex): The server's ID in hexadecimal notation.
- ServerId: The server's ID in decimal notation.
- HostPort: The IP address of the NFS server.
- HostName: The hostname assigned to the NFS server.
- Last Heartbeat (s) : The timestamp for the last received heartbeat.
- State: Is the NFS server ACTIVE (in use at present)

Volumes

Description: Displays information about the volumes on the container:

- **Volume Name:** The name of the volume. Click the name of the volume to view the containers of the volume (including the container ID, size (in MB), container primary location and container locations, and replication type, which can be S for sequential and C for cascading).
- **Mount Point:** The path in which the volume is mounted over NFS.
- **Mounted:** Specifies whether volume is mounted. Value can be Y or N.
- **ReadOnly:** Specifies whether volume is a read-only or read/write volume. Value can be Y (if volume is read-only) or N (if volume is read/write).
- **Volume ID:** The Volume ID.
- **Volume Topology:** The path describing the topology to which the volume is assigned.
- **Quota:** The total size of the volume's quota. A quota of 0 means no quota is assigned.
- **Advisory Quota:** The usage level that triggers a disk usage warning.
- **Used:** Total size of data written to the volume after compression.
- **LogicalUsed:** Actual size of data written to the volume.
- **Root Container ID:** The ID of the root container.
- **Replication:** The number of copies of the volume.
- **Guaranteed Replication:** The minimum number of copies of the volume.

Accountable Entities

Description: Displays information about users and groups:

- **AE Name:** The name of the accountable entity.
- **AE Type:** The type of accountable entity.
- **AE Quota:** The hard quota allocated to the accountable entity.
- **AE Advisory Quota:** The advisory quota limit for the accountable entity.
- **AE Used:** The amount of disk space used by the accountable entity.

Mirrors Information

Description: Contains a link to the Mirrors page, which displays information about volume mirrors:

- **Mirror Volume Name:** The name of the mirror volume.

- **Mirror ID:** The ID of the mirror volume used for the last successful mirroring. This ID starts with 1 and is incremented by 1 after each mirroring.
- **Mirror NextID:** The ID to be used for the next mirroring operation.
- **Mirror Status:** The status of the mirroring operation.
- **Last Successful Mirror Time:** The date and time stamp from the last successful mirroring operation.
- **Mirror SrcVolume:** The source volume for the mirror volume.
- **Mirror SrcRootContainerID:** The source container ID for the mirror volume.
- **Mirror SrcClusterName:** The source cluster name for the mirror volume.
- **Mirror SrcSnapshot:** The source snapshot associated with the mirror volume.
- **Mirror DataGenerator Volume:** The first volume that generates data (RW Volume) in the mirror chain.
For example, if the mirror chain is **A > B > C**, then at C, the Mirror DataGenerator volume is A while the source volume is B.
- **Mirror DataGenerator snapshot time:** The time at which the last snapshot for the Mirror DataGenerator Volume was generated.

Snapshots Information

Description: Contains a link to the Snapshots page, which displays information about snapshots:

- **Snapshot ID:** The ID of the snapshot.
- **RW Volume ID:** The ID of the standard (or read/write) volume associated with the snapshot.
- **Snapshot Name:** The name of the snapshot.
- **Root Container ID:** The ID of the container.
- **Snapshot Size:** The size of the snapshot.
- **Snapshot InProgress:** The status of the snapshot if it is currently in progress.

The page also displays a list of snapshot containers, and the following information about each:

- **Snapshot Container ID:** The unique ID of the container.
- **Snapshot ID:** The ID of the snapshot corresponding to the container.
- **RW Container ID:** The corresponding source container ID.

- Latest Epoch: The latest sequence number of the snapshot. Higher the number, the newest and most up-to-date is the snapshot.
- SizeMB: The container size, in MB.
- Container Master Location: The location of the container's primary replica.
- Container Locations: The location of the data containers.
- Inactive Locations: The location of inactive containers.

Storage Pools

Description: Displays information about storage pools:

- SP: The ID of the storage pool.
- ServerId: The ID of the server associated with the storage pool.
- Spldx: The index of the storage pool.
- Last Heartbeat(s): The timestamp for the last received heartbeat.
- Capacity: The total capacity of the storage pool.
- Used: The amount of space used on the storage pool.
- Disk Fullness Level (percentage): The percentage of disk space (associated with the storage pool) that is full.
- InTransit: Indicates that some containers in the storage pool are being resynced.
- OutTransit: Indicates that none of the containers in the storage pool are being resynced.

Active Container Moves

Description: Displays information about the containers being moved:

- Container ID: The ID of the container being moved.
- SizeMB: The size (in MB) of the container being moved.
- From Location: The location from where the container is being moved.
- From SP: The SP out of which the container is being moved.
- To Location: The location to which the container is being moved.
- To SP: The SP to which the container is being moved.

[Listing CLDB Nodes](#) on page 1807

Describes how to list CLDB nodes in the HPE Data Fabric.

Listing CLDB Nodes

Describes how to list CLDB nodes in the HPE Data Fabric.

Use the [nodelist cldbs](#) command to list all the CLDB nodes for a specified cluster.

For example:

```
# maprcli node listcldbs -cluster my.cluster.com -json
{
  "timestamp":1529445021408,
  "timeofday":"2018-06-19 02:50:21.408 GMT-0700 PM",
  "status":"OK",
  "total":1,
  "data":[
    {
      "CLDBs":"in111-22.qa.lab,in111-24.qa.lab,in111-21.qa.lab"
    }
  ]
}
```

Alternatively, use the [maprcli node list](#) command to find out whether a node is a CLDB node.

SSH into the node as root or the Data Fabric admin user, and issue the following command:

```
maprcli node list -columns svc,ip
```

A node is a CLDB node if the service list includes cldb as one of the services. For example:

```
$ maprcli node list -columns svc,ip
hostname
service
ip
mynode.mycompany.net
s3server,historyserver,resource manager,files server,cldb,nfs,mastgateway,hosts
tats,apiserver 10.163.167.210
```

Describes how to view CLDB information from the CLDB page, and provides an explanation of each field that the page displays.

Managing Drill

Provides a short description on managing Drill services.

You can install and run a Drillbit service on one node or on all of the nodes on a Data Fabric cluster to form a distributed cluster environment. After you have installed Drill and configured connections to your data sources, you can view Drill metrics and manage Drillbits using the Control System.

Viewing Drill Information

Explains how to view Drill information using the Control System.

Viewing Drill Information Using the Control System

Procedure

1. Log in to the Control System and click **Services**.

NOTE: The **Services** page is not available on the Kubernetes version of the Control System.

2. Click **Drill** in the **Services** pane.

The **Drill** information page displays the following:

Summary

The **Summary** tab displays the following panes:

Information	Displays the number of Drillbits and the number of completed and in-progress queries.
Resource Utilization	The percentage of CPU, memory, and disk space utilized by Drill.
Running Fragments	<p>The number of query fragments running in the Drillbit during the selected date and time range. You can select a preset (last 15 minutes, last 1 hour, last 12 hours, last 7 days, last 30 days, last 90 days) or custom time range and zoom in (by clicking and dragging your mouse in the pane) for a more granular view.</p> <p>For more information on fragments, see Drill Query Execution.</p>
Memory Used	<p>The amount of direct memory used by the JVM during the selected date and time range. You can select a preset (last 15 minutes, last 1 hour, last 12 hours, last 7 days, last 30 days, last 90 days) or custom time range and zoom in (by clicking and dragging your mouse in the pane) for a more granular view.</p> <p>To configure the amount of direct memory allocated to a Drillbit for query processing in a Drill cluster, see Configuring Drill Memory.</p>
Queries	The number of queries during the selected time range. You can select a preset (last 15 minutes, last 1 hour, last 12 hours, last 7 days, last 30 days, last 90 days) or custom time range and zoom in (by clicking and dragging your mouse in the pane) for a more granular view.

NOTE: The metrics collection infrastructure must be installed during installation to visualize the metrics in the various panes. If the metrics collection infrastructure is not installed, perform an [Incremental Install](#) to install the metrics collection infrastructure.

Drill Bits

The **Drill Bits** tab displays the list of Drillbits. See [Viewing the List of Drillbits](#) on page 1808.

Viewing the List of Drillbits

Explains how to view the list of Drillbits using the Control System.

About this task

Procedure

- Log in to the Control System and go to the **Drill Bits** tab in the [service information page](#) for Drill.
For each Drillbit, the pane displays the following:

Column Name	Column Description
Drill Bit ID	The ID of the Drillbit.
Node	The node on which the Drillbit is installed.
Service State	The status of the service. Value can be: <ul style="list-style-type: none"> Running Stopped
Queries in Progress	The number of queries currently in progress.
Resource Usage - Memory	The percentage of memory being used.
Resource Usage - CPU	The percentage of CPU being used.

Select the checkbox beside one or more Drillbit IDs to:

- Stop the Service(s)**
- Start the Service(s)**
- Restart the Service(s)**

For more information, see [Stopping, Starting, and Restarting Drillbits](#) on page 1809.

Stopping, Starting, and Restarting Drillbits

Explains how to stop, start and restart Drillbits using the Control System.

Stopping Drillbits

Procedure

- Log in to the Control System and go to the **Drill Bits** tab in the [service information page](#) for Drill.
- Select the checkbox associated with the Drillbit(s) and click **Stop Service(s)** to display the **Stop Service** confirmation dialog.
You can only stop Drillbits that are currently in running state.
- Review the list of Drillbits and click **Stop Service** to stop the Drillbits.

Starting Drillbits

Procedure

- Log in to the Control System and go to the **Drill Bits** tab in the [service information page](#) for Drill.
- Select the checkbox associated with the Drillbit(s) and click **Start Service(s)** to display the **Start Service** confirmation dialog.
You can only start Drillbits that are currently in stopped state.
- Review the list of Drillbits and click **Start Service** to start the Drillbits.

Restarting Drillbits

Procedure

1. Log in to the Control System and go to the **Drill Bits** tab in the [service information page](#) for Drill.
2. Select the checkbox associated with the Drillbit(s) and click **Restart Service(s)** to display the **Restart Service** confirmation dialog.
3. Review the list of Drillbits and click **Restart Service** to restart the Drillbits.

Managing the HPE Data Fabric NFS Service

Provides an overview of managing the NFS for the HPE Data Fabric service on a licensed cluster.

The Data Fabric NFS for the HPE Data Fabric service lets you access data on a licensed HPE Data Fabric cluster using the [NFS](#) protocol:

- Community Edition license: one NFS for the HPE Data Fabric node allows you to access your cluster as a standard POSIX-compliant file system.
- Enterprise Edition or Enterprise Database Edition license: multiple NFS servers allow each node to mount its own Data Fabric file system on NFS for the HPE Data Fabric enabled with VIPs for high availability (HA) and load balancing.

You can mount the Data Fabric cluster using NFS for the HPE Data Fabric, and use standard shell scripting to read and write live data on the cluster. NFS for the HPE Data Fabric access to cluster data can be faster than accessing the same data with the hadoop commands. To mount the cluster using NFS for the HPE Data Fabric from a client machine, see [Accessing Data with NFS v3](#).

Managing VIPs for NFS

Explains how to use virtual IP addresses (VIPs) on NFS servers.

You can set up a pool of NFS servers on various nodes in your cluster and connect to them using virtual IP addresses (VIPs) to achieve High Availability (HA) with failover; if one node fails, the VIP will automatically be reassigned to another NFS node in the pool. If you do not specify a list of NFS nodes to form a pool, then Data Fabric uses any available node running the Data Fabric NFS Gateway service. VIPs are not assigned to any nodes that are not on the list, regardless of whether they are running NFS.

NOTE: To add a server to an NFS pool that is not divided into subnets, start the Data Fabric NFS service on that server. The Data Fabric cluster automatically detects it and adds it to the pool.

The following illustration shows three nodes (Host1, Host2, and Host3) acting as NFS servers. Each node has two NICs whose ports are labeled eth0 and eth1. The NICs are grouped into two subnets, called Subnet A and Subnet B. Clients can access any of the NFS servers through a pool (or range) of VIPs assigned to each subnet. Data Fabric assigns each VIP address in the pool at random to a MAC address in the subnet (with its corresponding physical IP address).

The initial VIP assignment shown above is summarized in the following table. If one NFS server becomes unavailable, the VIP assigned to that server is automatically assigned to another server on the same subnet.

Server	Subnet	VIPs (randomly assigned)
NFS1	A	VIP2
NFS2	A	VIP3
NFS3	A	VIP1
NFS1	B	VIP4
NFS2	B	VIP6
NFS3	B	VIP5

If the cluster's NFS nodes have multiple network interface cards (NICs) connected to different subnets, you should restrict VIP assignment to the NICs that are on the correct subnet: for each NFS server, choose whichever MAC address is on the subnet from which the cluster will be NFS-mounted, then add it to the list.

WARNING: If you add a VIP that is not accessible on the subnet, then failover will not work. Also, do not use duplicate MAC addresses. For example, for bonding interfaces on the cluster nodes, do not use the same MAC address for bond0 and bond0.X, as then the failover of VIP might not work.

You can only set up VIPs for failover between network interfaces that are in the same subnet. In large clusters with multiple subnets, you can set up multiple groups of VIPs to provide NFS failover for the different subnets.

VIPs are evenly distributed across NFS nodes. For example, if six VIP addresses are available for three NFS servers, two VIPs are assigned to each server. If the previous example did not have two separate subnets, the six VIP addresses might be assigned like this:

Server	VIPs (randomly assigned)
NFS1	VIP1, VIP3
NFS2	VIP4, VIP5
NFS3	VIP2, VIP6

The following sections describe how to set up, edit, and remove VIPs using the Control System and the CLI.

Using Consistent Export Rules

Lists the default NFS export rules.

Export rules (stored in `conf/exports`) should be the same across all NFS nodes that are in the same VIP pool, and for nodes that are configured for the same VIP failover. The default version of `conf/exports` is as follows:

```
# Sample Exports file

# for non /mapr exports
# <Path> <comma separated cldb addresses=host:port> <exports_control>

# for /mapr exports
# <Path> <exports_control>

#access_control -> order is specific to default
# list the hosts before specifying a default for all
# a.b.c.d,1.2.3.4(ro) d.e.f.g(ro) (rw)
# enforces ro for a.b.c.d & 1.2.3.4 and everybody else is rw

# special path to export clusters in mapr-clusters.conf. To disable
exporting,
# comment it out. to restrict access use the exports_control
#
/mapr (rw)

#to export only certain clusters, comment out the /mapr & uncomment.
# Note: this will cause /mapr to be unexported
#/mapr/clustername (rw)

#to export /mapr only to certain hosts (using exports_control)
#/mapr a.b.c.d(rw),e.f.g.h(ro)

# export /mapr/cluster1 rw to a.b.c.d & ro to e.f.g.h (denied for others)
#/mapr/cluster1 a.b.c.d(rw),e.f.g.h(ro)

# export /mapr/cluster2 only to e.f.g.h (denied for others)
#/mapr/cluster2 e.f.g.h(rw)

# export /mapr/cluster3 rw to e.f.g.h & ro to others
#/mapr/cluster2 e.f.g.h(rw) (ro)
```

Setting Up VIPs for NFSv3

Explains how to set up VIPs for NFS version 3 using either the Control System or the CLI.

About this task

NOTE: The NFSv3 server (mapr - nfs3server) nodes cannot failover to NFSv4 server (mapr - nfs4server) nodes and vice versa. Ensure that different sets of VIPs are assigned for NFSv3 and NFSv4 server nodes. When running the `maprccli virtualip add` command to set up VIPs, list the MACs of the respective nodes so that the failover works properly (this is necessary when both NFSv3 and NFSv4 are going to be set up on the same cluster). The MACs should be mutually exclusive as both NFSv3 and NFSv4 servers cannot run on the same node.

Adding VIPs Using the Control System

About this task

You can use the Control System to specify a range of virtual IP addresses and assign them to the pool of servers that are running the NFS service. You can also restrict the assignment of virtual IP addresses to certain subnets.

Before following this procedure, make sure:

- You have installed NFS on at least three nodes (recommended).
- You have started the NFS gateway service on the servers to which you plan to assign VIPs.

Procedure

1. Log in to the Control System, click **Services**, and go to the [NFS service information page](#) where you can configure VIPs for NFSv3 nodes.

NOTE: The **Services** page is not available on the Kubernetes version of the Control System.

2. Click **Add Virtual IP** to display the **Add Virtual IP** page.
3. Enter the start of the VIP range in the **Starting Virtual IP** field.
HPE Data Fabric distributes the VIPs in this range to the selected network interfaces. VIPs are automatically migrated between the network interfaces when failures occur.
4. Enter the end of the VIP range in the **Ending Virtual IP** field.
If you are assigning only one VIP, you can leave the field blank. HPE Data Fabric distributes the VIPs in this range to the selected network interfaces. VIPs are automatically migrated between the network interfaces when failures occur.
5. Enter the Netmask for the VIP range in the **Netmask** field.
For example: 255 . 255 . 255 . 0. HPE Data Fabric assigns this netmask to the network interfaces along with the VIPs.
6. Specify whether (**Yes**) or not (**No**) to assign a particular VIP address to a specific server or MAC address. If **Yes**, enter the MAC address for the network interface to be assigned to the Starting Virtual IP address. The remaining VIP addresses from the same pool are assigned randomly.
7. Select one of the following:
 - **Use all network interfaces on all nodes that are running the NFS Gateway service** to set up VIPs that use all network interfaces on all the nodes running the NFS Gateway service.
If additional NFS Gateway services are started, the network interfaces on their nodes will automatically become candidates for the VIPs in this range.
 - **Select network interfaces** to restrict the assignment of virtual IP addresses to certain subnets:

A list of available and selected node names, physical IP addresses, and MAC addresses displays. Select from the:

- Available list and click ► to move selection to **Selected** VIPs.
- Selected list and click ◀ to remove from selected list of VIPs.

See [Designating NICs for HPE Data Fabric](#) on page 1416.

8. Confirm the actual VIP assignment by clicking **Save Changes**.

It might take up to 40 seconds to assign the VIPs. If necessary, refresh the page in your browser to view the list of VIPs.

Adding VIPs Using the CLI and REST API

About this task

CLI

The basic command to set up VIPs is:

```
maprcli virtualip
add -netmask <netmask> -virtualip
<virtualip> -service nfs3 -json
```

REST

Send a request of type POST. For example:

```
curl -X POST 'https://<host>:8443/
rest/virtualip/add?
service=nfs3&netmask=<netmask>&virtual
ip=<vip>' --user <username>:<password>
```

For the complete list of required and optional parameters, see [virtualip add](#) on page 2899.

Setting Up VIPs for NFSv4

Describes how to setup Virtual IPs (VIPs) for high availability of NFSv4 servers, using either the Control System or the CLI.

About this task

NOTE: NFSv4 refers to NFS version 4.1.

Virtual IP addresses (VIPs) allow you to achieve high availability with failover when the NFS servers use them to connect to your cluster. When configuring VIPs for NFSv4 servers, ensure that you select NFSv4 server nodes only. HPE Data Fabric does not support failing over between NFSv3 and NFSv4 servers.

Adding VIPs Using the Control System

About this task

You can use the Control System to specify a range of virtual IP addresses and assign them to the pool of servers that are running the NFS service. You can also restrict the assignment of virtual IP addresses to certain subnets.

Before following this procedure, make sure that:

- You have installed NFS on at least three nodes (recommended).
- You have started the NFS gateway service on the servers to which you plan to assign VIPs.

Procedure

1. Log in to the Control System and go to the [NFS4 service information page](#) where you can configure VIPs for NFSv4 nodes.
2. Click **Add Virtual IP** to display the **Add Virtual IP** page.
3. Enter the start of the VIP range in the **Starting Virtual IP** field.
HPE Data Fabric distributes the VIPs in this range to the selected network interfaces. VIPs are automatically migrated between the network interfaces when failures occur.
4. Enter the end of the VIP range in the **Ending Virtual IP** field.
If you are assigning only one VIP, you can leave the field blank. HPE Data Fabric distributes the VIPs in this range to the selected network interfaces. VIPs are automatically migrated between the network interfaces when failures occur.
5. Enter the Netmask for the VIP range in the **Netmask** field.
For example: 255 . 255 . 255 . 0. HPE Data Fabric assigns this netmask to the network interfaces along with the VIPs.
6. Specify whether (**Yes**) or not (**No**) to assign a particular VIP address to a specific server or MAC address. If **Yes**, enter the MAC address for the network interface to be assigned to the Starting Virtual IP address. The remaining VIP addresses from the same pool are assigned randomly.
7. Select one of the following:
 - **Use all network interfaces on all nodes that are running the NFS Gateway service** to set up VIPs that use all network interfaces on all the nodes running the NFS Gateway service.
If additional NFS Gateway services are started, the network interfaces on their nodes automatically become candidates for the VIPs in this range.
 - **Select network interfaces** to restrict the assignment of virtual IP addresses to certain subnets:
The system displays a list of available and selected node names, physical IP addresses, and MAC addresses. Do one of the following:
 - Select from the available list and click ► to move the selection to **Selected** VIPs.
 - Choose from the selected list and click ◀ to remove the chosen entries from the selected list of VIPs.

See [Designating NICs for HPE Data Fabric](#) on page 1416.
8. Confirm the actual VIP assignment by clicking **Save Changes**.
It might take up to 40 seconds to assign the VIPs. If necessary, refresh the page in your browser to view the list of VIPs.

Setting up VIPs for NFSv4 Server from the Command-Line

About this task

To set up VIPs for NFSv4 server:

Procedure

1. Add VIPs to the NFS server nodes in the cluster by running the [virtualip add](#) on page 2899 command.

```
maprccli virtualip add -virtualip <vip> -virtualipend <vipend> -service
nfs4 -netmask <netmask> -macs <mac>
```

For example, for a range of virtual IPs use:

```
maprccli virtualip add -virtualip 10.10.104.203 -virtualipend
10.10.104.206 -service nfs4 -netmask 255.255.255.0 -macs
"18:e7:28:2e:b0:80 18:e7:28:2e:2d:a0 18:e7:28:2e:2d:a8"
```

For a single virtual IP, do not include the `-virtualipend` parameter. For example:

```
maprccli virtualip add -virtualip 10.10.104.203 -service nfs4 -netmask
255.255.255.0 -macs
"18:e7:28:2e:b0:80 18:e7:28:2e:2d:a0 18:e7:28:2e:2d:a8"
```

For the complete list of required and optional parameters, see [virtualip add](#) on page 2899.

2. Add the hostname for each VIP in the `/etc/hosts` file on all the nodes in the cluster.
3. Add the principal for each VIP and generate the keytab file. That is, repeat this step in the following order for each VIP:
 - a) Add the principals for the following:
 - NFS server hostnames in the kerberos server.
 - VIP hostname in the kerberos server.
 - b) Generate the keytab file, which contains entries for all the NFS server and VIP hostname principals.
4. Restart the `rpc.gssd` service on all the NFSv4 server nodes.
To restart, run the following command:

```
service rpcgssd start
```

5. Mount the cluster.

Editing a VIP

Explains how to modify the Virtual IP (VIP) range using either the Control System or the CLI.

Editing a VIP Using the Control System

Procedure

1. Log in to the Control System and go to the [service information page](#) for NFS.
2. Click the **VIP Range** to modify.
The **Edit Virtual IP** page displays.

3. Modify changes to one or more of the following as needed.

Preferred MAC Address	The preferred MAC for this virtual IP. When an NFS server restarts, the HPE Data Fabric system attempts to move all of the virtual IP addresses that list a MAC address on this node as a preferred MAC to this node. If the new value is null, this field resets the preferred MAC value.
Select network interfaces	The list of MAC addresses that represent the NICs on the nodes to which the VIPs in the VIP range can be associated. Use this list to limit VIP assignment to NICs on a particular subnet when your NFS server is part of multiple subnets.

4. Click **Save Changes** for the changes to take effect.

Editing a VIP Using the CLI and REST API

About this task

CLI

The basic command to modify a VIP range is:

```
maprcli virtualip edit -netmask
<netmask> -virtualip <virtualip>
```

REST

Send a request of type POST. For example:

```
curl -X POST 'https://<host>:8443/
rest/virtualip/edit?
netmask<netmask>&virtualip=<vip>' --us
er <username>:<password>
```

For the complete list of required and optional parameters, see [virtualip edit](#) on page 2902.

Viewing the List of Virtual IPs

Explains how to view the list of VIPs using either the Control System or the CLI.

Viewing the List of VIPs Using the Control System

Procedure

- Log in to the Control System and go to the [service information page](#) for NFS.

The page displays the following:

Column Name	Column Description
VIP Range	The Virtual IP range.
Virtual IP	The VIP (in the range) of the associated node.
Node Name	The host name of the node.
Physical IP	The physical IP of the associated node.
MAC Address	The MAC address of the network interface that is assigned to the associated VIP.

You can add and remove VIPs.

*Retrieving the List of VIPs Using the CLI and REST API***About this task****CLI**

The basic command to retrieve a list of VIPs is:

```
maprccli virtualip list
```

REST

Send a request of type GET. For example:

```
curl -X GET 'https://<host>:8443/rest/virtualip/list' --user
<username>:<password>
```

For complete reference, see [virtualip list](#) on page 2904.

Removing a VIP

Explains how to remove a VIP range using either the Control System or the CLI.

*Removing a VIP Range Using the Control System***Procedure**

1. Log in to the Control System and go the [service information page](#) for NFS.
2. Select the VIP range(s) to remove and click **Remove Virtual IP**.
The **Remove Virtual IP** confirmation dialog displays.
3. Review the VIP range(s) to remove and click **Remove Virtual IP**.

*Removing a VIP Range Using the CLI or REST API***About this task**

The basic command to remove a VIP range is:

```
maprccli virtualip remove -virtualip <virtual IP>
```

For complete reference information, see [virtualip remove](#) on page 2908.

Accessing Data with NFS v3

Describes how Data Fabric works with NFS v3.

Unlike other Hadoop distributions that only allow cluster data import or import as a batch operation, Data Fabric lets you mount the cluster itself using NFS for the Data Fabric so that your applications can read and write data directly. Data Fabric allows direct file modification and multiple concurrent reads and writes using POSIX semantics. With a NFS-mounted cluster, you can read and write data directly with standard tools, applications, and scripts. For example, you could run a MapReduce application that outputs to a CSV file, then import the CSV file directly into SQL using NFS for Data Fabric.

Data Fabric exports each cluster as the directory `/mapr/<cluster name>` (for example, `/mapr/my.cluster.com`). If you create a mount point with the local path `/mapr`, then Hadoop FS paths and NFS v3 paths to the cluster will be the same. This makes it easy to work on the same files using NFS v3 and Hadoop. In a multi-cluster setting, the clusters share a single namespace, and you can see them all by mounting the top-level `/mapr` directory.

WARNING: Data Fabric uses version 3 of the NFS protocol. NFS version 4 bypasses the port mapper and attempts to connect to the default port only. If you are running NFS on a non-standard port, mounts from NFS version 4 clients time out. Use the `-o nfsvers=3` option to specify NFS v3.

CAUTION: It is observed that NFS v3 clients are caching older [atime values](#) from previous history. Therefore, you might observe wrong `atime` values. To mitigate, make sure to clear caches, before checking file timestamps.

You can mount the cluster on a Linux, Mac, or Windows client. Before you begin, make sure you know the hostname and directory of the NFS v3 share you plan to mount.

Starting, Stopping, and Restarting HPE Data Fabric NFSv3

Explains how to start, stop, and restart NFS version 3 using either the Control System or the CLI.

Starting, Stopping, and Restarting HPE Data Fabric NFSv3 Using the Control System

About this task

See:

- [Starting the Services on the Cluster Using the Control System](#) on page 1401
- [Stopping a Service on the Cluster Using the Control System](#) on page 1402
- [Restarting the Services on the Cluster Using the Control System](#) on page 1403

Starting, Stopping, and Restarting HPE Data Fabric NFSv3 Using the CLI and REST API

About this task

NFSv3 Server

The command to stop, start, or restart HPE Data Fabric NFSv3 server is:

```
maprccli node services -nodes <node
names> -nfs stop|start|restart
```

REST

Send a request of type POST. For example:

```
curl -X
POST 'https://<host>:8443/rest/node/
services?nodes=<nodeName>&nfs=stop|
start|restart' -- user
<username>:<password>
```

NOTE: When NFS server is stopped, the VIPs associated with the server are released, and CLDB attempts to reassign the VIPs to other available NFS servers. For the complete list of parameters, see [node services](#) on page 2598.

Setting Up Aliases for NFS Exports

About this task

When provisioning file system for various tenants, you can set up an alias for the path in file system, rather than exporting the whole path, to mask the path from the users. Once the alias is set up, users will not be able to access or mount the path in file system.

Aliases can be set up for the cluster, volume, and directory, but not for the root of the path in file system (`/mapr`). To set up an alias for a path in file system:

Procedure

1. Open the NFS exports file in `/opt/mapr/conf/` directory.

2. Specify the alias name for the mount path using the following syntax:

```
<path in MFS> /<alias name> <options>
```

Here:

<path in MFS>	Refers to the file system mount path. If this points to a: <ul style="list-style-type: none">• Volume, the user can access the snapshots associated with the volume.• Directory, the user cannot access the snapshots.
/<alias name>	Refers to the alias name to use. If there are duplicate aliases in the file, the last entry will take effect and all other duplicate entries will be ignored. If the alias name is not specified, the path in file system will be exported.
<options>	The list of available/supported options.

For example, suppose a file system mount path of `/mapr/samplecluster/samplevolume` for tenant `samplecustomer`. To set up an alias, add the following to the exports file:

```
/mapr/samplecluster/samplevolume /samplecustomer (rw)
```

For example, to export a certain cluster, volume, or a subdirectory as an alias, comment out `/mapr` and add the following:

```
/mapr/clustername /alias1 (rw)
/mapr/clustername/vol /alias2 (rw)
/mapr/clustername/vol/dir /alias3 (rw)
```

 **NOTE:** Only the alias will be visible/exposed to the NFS client.

3. Run the following command for the file changes to take effect:

```
/opt/mapr/bin/maprccli nfsmgmt refreshexports
```

4. Run the following command to export the path:

```
mount -t nfs nfsServer:/<alias_name> /localpath
```

Run this command once for each entry in the file.

What to do next

The same export rules must be set up on all the NFS servers in the cluster to ensure that in the event of a node failure, the same aliases work with VIP failover.

Mounting NFS for the HPE Data Fabric to file system on a Cluster Node

You can *automatically* or *manually* mount NFS for the HPE Data Fabric to the file system on a cluster node.

 **NOTE:** The procedure works only on nodes where NFS service is installed.

Automatically Mount

 **ATTENTION:** The root user must not be the owner of the `/mapr` mount point.

Use this procedure to *automatically* mount NFS for the HPE Data Fabric to file system on the cluster `my.cluster.com` at the `/mapr` mount point.

1. Set up the mount point by creating the directory.

```
sudo mkdir /mapr
```

2. Run the chown command to change the owner of the /mapr mount point.

```
sudo chown <user ID of Data Fabric user>:<group ID of Data Fabric user> /mapr
```

3. Add the following line to /opt/mapr/conf/mapr_fstab:

```
<hostname>:/mapr /mapr hard,no lock
```

NOTE: The change to /opt/mapr/conf/mapr_fstab will not take effect until Warden is restarted.

Every time your system is rebooted, the mount point is automatically re-established according to the mapr_fstab configuration file.

Manually Mount

Use this procedure to *manually* mount NFS for the HPE Data Fabric to file system on the cluster *my.cluster.com* at the /mapr mount point.

1. Set up a mount point for a NFS for the HPE Data Fabric share.

```
sudo mkdir /mapr
```

2. Mount the cluster via NFS for the HPE Data Fabric.

```
sudo mount -o hard,no lock usa-node01:/mapr /mapr
```

NOTE: When you mount manually from the command line, the mount point does not persist after a reboot.

Mounting NFS on a Linux Client

Explains how to mount NFS on a Linux client either automatically at start up or manually.

You can *automatically* or *manually* mount NFS on a Linux client when your system starts up.

Automatically Mount

Use this procedure to *automatically* mount to NFS on a Linux client when your system starts up.

Add an NFS mount to /etc/fstab.

#	device	mountpoint	fs-type	options	dump	fsckorder
...						
	usa-node01:/mapr	/mapr_nfs/	nfs	rw	0	0
...						

Manually Mount

Use this procedure to *manually* mount to NFS on a Linux client.

1. Install the NFS client.

- `sudo yum install nfs-utils` (Red Hat or CentOS)

- `sudo apt-get install nfs-common` (Ubuntu)
- `sudo zypper install nfs-client` (SLES)

2. List the NFS shares exported on the server. For example:

```
showmount -e usa-node01
```

NOTE: If the NFS protocol is v4 only, the `showmount` command does not return the list of exported NFS shares. Instead, to view the export list, run the following command:

```
/opt/mapr/server/nfs4mgr list-exports
```

3. Set up a mount point for an NFS share. For example:

```
sudo mkdir /mapr_nfs/
```

4. Mount the cluster using NFS. Use the command as in the following example:

```
sudo mount -t nfs -o sec=mode vers=NFS_version usa-node01:/mapr /mapr_nfs/
```

where `mode` is one of the following:

- `krb5` for Kerberos version 5 authentication service.
- `krb5i` for Kerberos version 5 with integrity.
- `krb5p` for Kerberos version 5 with privacy.
- `none` for no authentication.

and `NFS_version` is either 3 or 4.

RESTRICTION: You can use the `sec=mode` option only for NFS version 4. NFS version 3 does not support this option.

TIP: For the best performance, use NFS v4.0.

Use the `vers=4.0` parameter in the mount command. For example:

```
mount -t nfs -o sec=krb5,vers=4.0 usa-node01:/mapr /mapr_nfs/
```

For NFS v3, use the command as in the following example:

```
mount -t nfs -o vers=3 usa-node01:/mapr /mapr_nfs/
```

NOTE: The mount point does not persist after reboot when you mount manually from the command line.

5. List all mounted file systems to verify that the cluster is mounted. For example:

```
$ mount | grep nfs4
usa-node01:/mapr on /mapr_nfs (nfs, nodev, nosuid, mounted by testUser)
```

Mounting NFS on a Mac Client

Describes how to mount a NFS server on a Mac client.

About this task

Use this procedure to mount to the cluster *manually* from the command line:

Procedure

1. Open a terminal. For example, you can click on **Launchpad > Open terminal**.
2. At the command line, enter the following command to become the root user:
`sudo bash`
3. List the NFS shares exported on the server. For example:

```
showmount -e usa-node01
```

4. Set up a mount point for an NFS share. For example:

```
sudo mkdir /mapr_nfs/
```

5. Mount the cluster using NFS. Use the command as in the following example:

```
sudo mount -t nfs -o vers=3 usa-node01:/mapr /mapr_nfs/
```

NOTE: The mount point does not persist after reboot when you mount manually from the command line.

6. List all mounted file systems to verify that the cluster is mounted. For example:

```
$ mount | grep nfs
usa-node01:/mapr on /mapr_nfs (nfs, nodev, nosuid, mounted by testUser)
```

Mounting NFS on a Windows Client

Describes how to mount an NFS share on a Windows client, and configure the relevant user and group IDs.

About this task

To set up the Windows NFS client, mount the cluster, map a network drive, and configure the user ID (UID) and group ID (GID). The Windows client must access NFS using a valid UID and GID from the Linux domain. Mismatched UID or GID results in permission problems when MapReduce jobs try to access files that were copied from Windows over an NFS share.

Due to Windows directory caching, the `.snapshot` directory may not appear in the root directory of each volume. As a workaround, you can force Windows to re-load the volume's root directory by updating its modification time (for example, by creating an empty file or directory in the volume's root directory).

With Windows NFS clients, use the `-o noLock` option on the NFS server to prevent the Linux NLM from registering with the portmapper. The native Linux NLM conflicts with the HPE Data Fabric NFS server.

Complete the following steps to mount NFS on a Windows client:

Procedure

1. Mount the Cluster.

Windows 10 Enterprise

Complete the following steps for *Windows 10 Enterprise*

- a. Open **Start > Control Panel > Programs**.
- b. Select **Turn Windows features on or off**.
- c. Select **Services for NFS**.
- d. Click **OK**.
- e. Enable write permissions for the anonymous user as the default options only grant read permissions when mounting a UNIX share using the anonymous user.

To grant write permissions, make a change to the Windows registry by performing the following steps:
 1. Open `regedit` by typing it in the search box and pressing **Enter**.
 2. Create a new **New DWORD (32-bit) Value** inside the `HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\ClientForNFS\CurrentVersion\Default` folder named `AnonymousUid` and `AnonymousGid` and assign the UID and GID found on the UNIX directory as shared by the NFS system.
- f. Restart the NFS client or reboot the machine to apply the changes.
- g. Mount the cluster and map it to a drive using the Map Network Drive tool or from the command line.

```
mount -o anon usa-node01:/mapr z:
```

For more information, see step 2.

Windows 7 Enterprise

Complete the following steps for *Windows 7 Ultimate* or *Windows 7 Enterprise*

- a. Open **Start > Control Panel > Programs**.
- b. Select **Turn Windows features on or off**.
- c. Select **Services for NFS**.
- d. Click **OK**.
- e. Mount the cluster and map it to a drive using the Map Network Drive tool or from the command line.

```
mount -o nolock usa-node01:/mapr z:
```

For more information, see step 2.

Other Versions of Windows

Complete the following steps for all other versions of Windows:

- a. Download and install Microsoft Windows Services for Unix (SFU). You only need to install the NFS Client and the User Name Mapping.
- b. Configure the user authentication in SFU to match the authentication used by the cluster (LDAP or operating system users). You can map local Windows users to cluster Linux users, if desired.
- c. Once SFU is installed and configured, mount the cluster and map it to a drive using the Map Network Drive tool or from the command line.

```
mount -o noexec usa-node01:/map  
z:
```

For more information, see step 2.

2. Map a network drive with the Map Network Drive tool.

- a) Open **Start > My Computer**.
- b) Select **Tools > Map Network Drive**.
- c) In the Map Network Drive window, choose an unused drive letter from the **Drive** drop-down list.
- d) Specify the folder by browsing for the MapR cluster, or by typing the hostname and directory into the text field.
- e) Browse for the MapR cluster or type the name of the folder to map. This name must follow UNC. Alternatively, click **Browse...** to find the correct folder by browsing available network shares.
- f) Select **Reconnect at login** to reconnect automatically to the MapR cluster whenever you log into the computer.
- g) Click **Finish**.

3. Configure the UID and GID for NFS access.

System that is part of Active Directory Domain

For a system that is part of the Active Directory Domain, you must instruct the NFS client to access an AD server to get uidNumber and gidNumber.

- a. Ensure that the AD Users schema has auxiliary class posixAccount.
- b. Populate the AD uidNumber and gidNumber fields with the matching uid and gid from Linux.
- c. Configure the NFS client to look up uid and gid in the AD DS store.
- d. Refer to details here: [http://technet.microsoft.com/en-us/library/hh509016\(v=ws.10\).aspx](http://technet.microsoft.com/en-us/library/hh509016(v=ws.10).aspx).

System not using Active Directory

For a standalone Windows 7 or Vista machine (not using Active Directory), Windows always uses its configured anonymous UID and GID for NFS access, which by default are -2. However, you can

configure Windows to use specific values, which results in being able to access NFS using those values.

The UID and GID values are set in the Windows Registry and are global on the Windows NFS client box. This solution might not work well if your Windows box has multiple users who each need access to NFS with their own permissions, but there is no obvious way to avoid this limitation.

The values are stored in the registry path `HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\ClientForNFS\CurrentVersion\Default`. The two DWORD values are `AnonymousUid` and `AnonymousGid`. If they do not exist, you must create them.

Refer to details here: <https://docs.microsoft.com/en-us/archive/blogs/msdn/sfu/can-i-set-up-user-name-mapping-in-windows-vista>.

4. (Optional) Deactivate the nlockmgr service.

If the nlockmgr service is active on a Windows machine, attempts to mount a HPE Data Fabric NFS share fail with the following message:

```
C:\Users\administrator.Client1>mount -o nolock -u:mapr -p:mapr
ClusterNode1:/mapr / g:
Network Error - 53
Type 'NET HELPMSG 53' for more information.
```

- a) Run the `rpcinfo` command to confirm that the nlockmgr service is active.

```
C:\Users\administrator.Client1>rpcinfo -p ClusterNode1
program version protocol    port
-----
100000      4      tcp      111      portmapper
100024      1      udp     60588      status
100007      2      udp       817      ypbind
100021      1      udp     47016      nlockmgr
100021      3      udp     47016      nlockmgr
100021      4      udp     47016      nlockmgr
100021      1      tcp     34254      nlockmgr
100021      3      tcp     34254      nlockmgr
100021      4      tcp     34254      nlockmgr
```

- b) Check the output for the presence of nlockmgr. To deregister nlockmgr services on the node, use the `-d` switch in `rpcinfo` on the HPE Data Fabric node.

```
rpcinfo -d 100021 1
rpcinfo -d 100021 2
rpcinfo -d 100021 3
rpcinfo -d 100021 4
```

- c) Re-check `rpcinfo` output to verify that no `nlockmgr` services are registered. The NFS mount completes successfully at this point.

```
C:\Users\administrator.Client1>mount -o nolock -u:mapr -p:mapr
ClusterNode1:/mapr/ Z:
Z: is now successfully connected to ClusterNode1:/mapr/
The command completed successfully.
```

Configuring Access When ACES are set

About this task

NOTE: NFSv4 refers to NFS version 4.1.

Some NFS clients, such as the Microsoft native Windows NFSv3 client, check mode bits to determine if access is allowed even before contacting the NFS server. If [ACEs](#) are set on a directory or file, the client-side permission checks based solely on mode bits prevent the client from accessing the file or directory. You can set the value for the `WindowsAceSupport` property to `true` in the `nfsserver.conf` on page 3376 file to allow the Windows client access to the file or directory. The default value for this property is `false`, and denies access to the client even before contacting the NFS server.

When the `WindowsAceSupport` property value is set to `true`, HPE Data Fabric returns mode bits 777 to the client if [ACE](#) is set on the file or directory, thus allowing the client to establish a connection to the server. However, when the client actually tries to read or write from the server, HPE Data Fabric performs permission checks against the mode bits and [ACEs](#) on the directory and/or file, ensuring proper access.

NOTE: When the `WindowsAceSupport` property value is set to `true`:

- Tools that visually display access information might show read/write access for users who do not have that access.
- Files that are not executables might appear executable.
- You cannot use the NFSv3 to access an NFSv4 server, because the NFSv4 server only supports the v4 protocol.

Configuring the Linux NFS Client

Describes how to set the optimal number of RPC requests to the NFS server.

About this task

The default RPC requests configuration can negatively impact performance and memory. To avoid performance and memory issues, configure the number of outstanding RPC requests to the NFS server to be 128.

Perform the following steps as the `root` user on each NFS client machine:

Procedure

1. To enable the configuration to persist after a reboot of the NFS client machine, issue the following commands to create the `sunrpc.conf` file under `/etc/modprobe.d` with the recommended configuration:

```
echo "options sunrpc tcp_slot_table_entries=128" >> /etc/modprobe.d/
sunrpc.conf
echo "options sunrpc tcp_max_slot_table_entries=128" >> /etc/modprobe.d/
sunrpc.conf
```

- To enable the configuration to take effect after you remount the NFS client to the NFS for the HPE Data Fabric gateway, issue the following echo commands:

```
echo 128 > /proc/sys/sunrpc/tcp_slot_table_entries
echo 128 > /proc/sys/sunrpc/tcp_max_slot_table_entries
```

- Remount the NFS client to the NFS for the HPE Data Fabric gateway. For example, the following commands unmount and mount NFS for the HPE Data Fabric assuming that the cluster is mounted at /mapr:

```
umount /mapr
mount -o hard,nolock <hostname>:/mapr /mapr
```

NOTE: Failure to configure this property may result in the following error in /opt/mapr/logs/nfsserver.log:

```
ERROR nfsserver[38960] fs/nfsd/requesthandle.cc:791 0.0.0.0[0]
cannot allocate more OncRpcContexts: [numDropped=2556001]
dropping connection from nfsc=10.13.64.225:0
```

TIP: For CentOS, after the reboot of the node, if the /proc/sys/sunrpc directory is not available or if rpcidmapd is not running, start the rpcidmapd service using the following command:

```
service rpcidmapd start
```

Accessing Data with NFS v4

Describes how HPE Data Fabric works with the NFS v4 protocol. Presents an overview of the process flow to read and write HPE Data Fabric processes with NFS v4, and a list of NFS v4 features that HPE Data Fabric does not support.

NOTE: NFSv4 refers to NFS version 4.1.

HPE Data Fabric lets you mount the cluster using NFS v4 so that your applications can read and write data directly. HPE Data Fabric allows direct file modification and multiple concurrent reads and writes using POSIX semantics. With an NFS v4-mounted cluster, you can read and write data directly with standard tools, applications, and scripts. For example, you could run a MapReduce application that outputs to a CSV file, then import the CSV file directly into SQL using NFS v4.

HPE Data Fabric uses NFS Ganesha for supporting NFS v4 features. NFS Ganesha is an Open Source userspace implementation of the NFS v4 server. The following table summarizes the NFS Ganesha versions used by various HPE Data Fabric release versions.

Data Fabric release version	NFS Ganesha release version used
Up to version 6.1	Version 2.3
Version 6.2 to version 7.6	Version 3.3
Version 7.7	Version 5.7

The HPE Data Fabric NFS v4, running as a userspace process, registers callbacks with NFS Ganesha through the File System Abstraction Layer (FSAL), which is a shared library (libfsalmapr.so). NFS Ganesha loads and uses this library whenever the file system is exported/mounted. The FSAL, in turn, uses FileClient (libMapRCClient.so) to connect to the cluster.

The following diagram illustrates how the HPE Data Fabric processes read and write operations to the HPE Data Fabric cluster using NFS v4. When the user enters a command (such as `ls`), the NFS client submits the request over TCP to the HPE Data Fabric NFS v4 server. The NFS v4 server uses the HPE Data Fabric FileClient to perform the requested operation on the cluster and returns the response to the NFS v4 client over TCP.

HPE Data Fabric exports each cluster as the directory `/mapr/<cluster name>` (for example, `/mapr/my.cluster.com`). If you create a mount point with the local path `/mapr`, then Hadoop FS paths and NFS v4 paths to the cluster are the same. This makes it easy to work on the same files using NFS v4 and Hadoop. In a multi-cluster setting, the clusters share a single namespace, and you can see them all by mounting the top-level `/mapr` directory.

For NFS v4, HPE Data Fabric also requires alias or pseudo-path, which when specified masks the mount path from the NFS v4 client. The HPE Data Fabric NFS v4 server provides a pseudo-file system where only the exported volumes are visible. This is especially useful in scenarios where one or more volumes in the hierarchy should be hidden and not be visible. For more information, see [NFS v4 RFC](#).

CAUTION: It is observed that NFS v4 clients are caching older `atime` values from previous history. Therefore, you might observe wrong `atime` values. To mitigate, make sure to clear caches, before checking file timestamps.

Unsupported NFS v4 Features

HPE Data Fabric does not currently support the following NFS v4 features:

- pNFS
- Delegations
- Mandatory locking
- Lock upgrades and downgrades
- Deny share

- [ACL](#)
- [ACE](#)
- Namespaces
- Persistent reply cache
- Data retention
- Attributes such as time_access, FATTR4_ARCHIVE, FATTR4_FILES_AVAIL, FATTR4_FILES_FREE, FATTR4_FILES_TOTAL, FATTR4_FS_LOCATIONS, FATTR4_MIMETYPE, FATTR4_QUOTA_AVAIL_HARD, FATTR4_QUOTA_AVAIL_SOFT, FATTR4_QUOTA_USED, FATTR4_TIME_BACKUP, and FATTR4_ACL

Configuring the NFSv4 Server

NOTE: NFSv4 refers to NFS version 4.1.

You can configure NFSv4 server by setting the values for the parameters in the `/opt/mapr/conf/nfs4server.conf` file. The configuration parameters are defined within blocks in the file. The following sections describe the blocks and required parameters (within each block) for the Data Fabric NFSv4 server.

By default, the NFSv4 server is configured to rely on a Kerberos infrastructure. If you don't want or don't have a Kerberos infrastructure, comment out the SecType parameter of the EXPORT section.

NFS_CORE_PARAM

Contains the general settings for the daemon. The parameters in this block should not be modified.

Clustered	The value is false. Do not modify this parameter.
Plugins_Dir	The directory for the FSAL libraries. The value is <code>/opt/mapr/lib</code> . Do not modify this parameter.
DRC_TCP_Size	The maximum number of results stored in the DRC. The default value is 16.
DRC_TCP_Recycle_Expire_S	The amount of time after which to expire results stored in DRC. The default value is 60 seconds.
Dirent_Entries_Track	Specifies whether (true) or not (false) to monitor dirent entries. If true, the process restarts if the number of dirent entries exceeds limit.
Num_Log_Files	The maximum number of log files. The default value is 1.

Max_Logfile_Size	<p>The maximum amount of space for each log file. The default value is 1073741824. The total amount of disk space for log files is calculated using the following:</p> <div>$\text{Num_Log_Files} * \text{Max_LogFile_Size}$</div> <p>For example, suppose Num_Log_Files = 32 and Max_LogFile_Size = 1GB. Then, the total disk space for log files is 32GB.</p>
Enable_RQUOTA	<p>Specifies whether (true) or not (false) to enable support for remote quotas. The default value is false.</p>
NFS_Protocols	<p>The supported NFS protocols. The only supported value is 4.</p>

NFSV4

Contains settings for the NFSv4 protocol. The following parameters should not be modified.

Delegations	boolean	<p>Specifies whether delegation is supported. The default value is false and should not be modified (cannot be set to true) as delegation is not supported.</p>
-------------	---------	---

Dirent_Cache_Threshold	128	<div>The threshold for caching directory entries. If directory entries exceed threshold, the entries are not cached; caching is enabled only if entries are below this threshold.</div> <div> NOTE: This should be used only if readdirplus is true.</div>
------------------------	-----	--

EXPORT_DEFAULTS

Contains default values for all subsequent EXPORT blocks. The settings in subsequent EXPORT blocks can override these default values on a per export basis.

Anonymous_Uid	The anonymous UID. The default value is -2, which is converted to a 32 bit unsigned integer (4294967294) when root squash is enabled.
Anonymous_Gid	The anonymous GID. The default value is -2, which is converted to a 32 bit unsigned integer (4294967294) when root squash is enabled.
Protocols	The supported NFS protocols. The default value is 4. This cannot be changed.

EXPORT

Contains settings for exporting a file system.

SecType	<p>The comma-separated list of supported authentication flavors for the export or the type of security. Value can be comma-separated list of:</p> <ul style="list-style-type: none"> • krb5 — authentication • krb5i — integrity • krb5p — privacy <p> NOTE: This <i>must</i> be specified if you want the clients to use kerberos ticket for secure access.</p>
Path	<p>(Required) The (cluster) path to export via NFS. The path should have a leading slash. If just /mapr is specified as the path, all the clusters (listed in the <code>mapr-clusters.conf</code> file) will be visible. To export only a specific cluster, specify the complete path to the cluster to export.</p> <p> NOTE: Exporting will not be successful if extra forward slash (/) characters are in the path. For example, the following path will not be exported because of the extra slash (shown in bold) in the path: /mapr/Test3//ATS-VOLUME</p>

Pseudo	(Required for NFSv4 protocol for every directory or volume to export) The pseudo path, which when specified, masks the mount path from the NFS client, for the NFSv4 exports. MapR's NFSv4 server provides a pseudo-file system where only the exported volumes are visible. This is especially useful in scenarios where one or more volumes in the hierarchy should be hidden and not be visible. When mounting with NFSv4, use the pseudo path. Value can be the volume or directory path.
Export_Id	<p>(Required) The tag used to set the ID for the export or the unique ID to associate with each export. Value should not be 0.</p> <p> NOTE: The export ID associated with each export must be the same across all NFSv4 servers on the cluster.</p>
Clients	The list of clients these export permissions apply to. Clients may be specified by hostname, IP address, netgroup, CIDR network address, host name wild card, or simply "*" to apply to all clients.
Squash	Specifies whether to enable or disable root squashing. By default, root squashing is disabled. If root squash is enabled, the values substituted for the root user will be anonymous user (Anonymous_Uid and Anonymous_Gid); that is, the UID and GID of a file created will not be nfsnobody because the default value of -2 is converted to a 32 bit unsigned integer (4294967294) instead of the 16 bit equivalent (65534), which is the value of nfsnobody.

Access_Type	(Required) The type of access on the mount point. Valid values include: <ul style="list-style-type: none">• RO — for read-only mount point• RW — for read/write mount point• MDONLY — for read/write access to metadata only• MDONLY_RO — for read-only access to metadata only
FSAL	(Required) The file system to use. Value must be MAPR to use the file system <code>libfsalmapr.so</code> library, which contains the shared library (<code>libMapRCClient</code>) and the callbacks.
Attr_Expiration_Time	The timeout value in seconds for file/directory (regular) attributes cache. This value is used to determine whether to use the cached attribute information (only if within the specified timeout window) or to fetch attribute information again. The default is 3.0 seconds, which specifies that cached attribute information must be considered stale and refreshed after 3.0 seconds. A value of 0 disables caching. For better performance, avoid disabling caching.

LOG

Contains configuration for logging. The default log level is INFO. Value can be one of the following:

- FATAL
- MAJ
- CRIT
- WARN
- EVENT
- INFO

- DEBUG
- MID_DEBUG
- FULL_DEBUG

MAPRFS

Contains configurations for NFS gateway access to the Data Fabric file system.

Parameter	Default Value	Description
log_path	/opt/mapr/ logs/nfs4	Path for the log files.
ra_sessions	5	<p>Number of parallel read ahead sessions per client library (libMapRClient.so). Each open file acts as one read ahead session. For example, if value is set to 5, up to 5 files can have read ahead sessions per client library (libMapRClient.so). To disable read ahead sessions, set value to 0.</p> <p> NOTE: The number of client libraries is 3 by default and cannot be configured.</p>

Parameter	Default Value	Description
flush_inline	true	<p>Specifies whether or not to flush all writes inline. Value can be:</p> <ul style="list-style-type: none"> • true — flush all writes inline • false — disable inline flushing <p>If enabled (default), writes are sent to server directly. If disabled, for all open files, the buffer is flushed automatically every 3 seconds or when it reaches 64KB.</p>
fast_local_directio	false	<p>Specifies whether to optimize or disable NFS client for local direct IO. Value can be:</p> <ul style="list-style-type: none"> • true — optimize • false — disable
nfs_track_memory	false	<p>Specifies whether to enable (true) or disable (false) memory tracking for NFS.</p>

Parameter	Default Value	Description
hb_interval	5	The interval (in seconds) for sending heartbeat to CLDB to allow CLDB to determine whether server is running. The CLDB will declare the NFS gateway dead when it loses about 8 heartbeats in a row and will trigger a failover.
req_threshold	5	The amount of time (in seconds) for processing requests. If the threshold is exceeded, warnings will be logged.

Parameter	Default Value	Description
client_lib_path	/tmp/nfs4	<p>The location for the client library (libMapRClient).</p> <p> NOTE: To install and use NFSv4 and FUSE-based POSIX client on the same node, ensure that the path for the client library for the NFSv4 and FUSE-based POSIX client is not /tmp. Specify a different location for the client libraries. For example, /tmp/nfs4lib.</p>
readdirplus	true	<p>Specifies whether (true) or not (false) to enable extended read from the directory. If enabled (true), each entry returns the name, the file ID, attributes (including the field), and file handle.</p>

**NOTE:**

- The `libnfsidmap` must be configured to use `nsswitch`, a translation mechanism for mapping names to IDs, in the `/etc/idmapd.conf` file.
- The NFSv3 (`mapr-nfsserver`) nodes cannot failover to NFSv4 server nodes and vice versa. Ensure that different set of VIPs are assigned for NFSv3 and NFSv4 server nodes. When running the `maprcli virtualip add` command to set up VIPs, list the MACs of the respective nodes so that the failover works properly (this is necessary if both NFSv3 and NFSv4 are going to be set up for same cluster). The MACs should be mutually exclusive as both NFSv4 and NFSv3 servers cannot run on the same node.

Sample Configurations

You can refer to the following sections, which contain blocks for the various required configurations using sample values.

NOTE: NFSv4 refers to NFS version 4.1.

Configuration for Supported NFS Protocols

To specify the supported NFS protocols, set the value for the `NFS_Protocols` parameter in the `/opt/mapr/conf/nfs4server.conf` file. For example, for NFSv4 protocol, in the `/opt/mapr/conf/nfs4server.conf` file, set the value for the `NFS_Protocols` parameter as shown (in bold) below.

```
NFS_CORE_PARAM
{
    Plugins_Dir = /opt/mapr/lib;
    NFS_Protocols = 4;
    Clustered = false;
}
```

NOTE: The only supported protocol is 4.

For NFSv4, the `showmount` command does not return the list of exported NFS shares.

Configuration for Mounting the Cluster

Add the MAPRFS block in the `/opt/mapr/conf/nfs4server.conf` file as shown below.

```
MAPRFS
{
    #Directory path where nfsv4 logs should be stored
    log_path = /opt/mapr/logs/nfs4;

    #Set number of readahead sessions
    ra_sessions = 5;

    #Flush all writes inline
    flush_inline = true;

    #Optimize for local direct writes
    fast_local_directio = false;

    #Set security ticket file
    tkt_location = /tmp/maprticket_XXX;

    #Hearbeat interval for NFSv4 (in seconds)
    hb_interval = 5;
```

```
#Request threshold, logs warning if any request takes more time (in
seconds)
req_threshold = 5;
}
```

Configuration for Exporting the File System

Modify the EXPORT block in the `/opt/mapr/conf/nfs4server.conf` file as shown (in bold) below. The following sample block shows a standard configuration where the exported path and the actual path are the same.

```
EXPORT
{
    # Export Id (mandatory, each EXPORT must have a unique Export_Id)
    Export_Id = 77;

    # Exported path (mandatory)
    Path = /mapr;

    # Pseudo Path (required for NFS v4)
    Pseudo = /mapr;
    Squash = No_Root_Squash;

    # Required for access (default is None)
    # Could use CLIENT blocks instead
    Access_Type = RW;

    # Security type (krb5,krb5i,krb5p)
    SecType = krb5;

    # Exporting FSAL
    FSAL {
        Name = MAPR;
    }
}
```

NOTE: If you change anything in the export block, restart NFSv4 service and remount the path.

Configuration for Pseudo Path

To mask the path to the volume from the client, set the pseudo path. For the pseudo path, you can specify a value that is different from the path parameter to hide the true path name. To hide the full path to volumes and/or directories, specify the complete path in the EXPORT block.

For example, modify the EXPORT block in the `/opt/mapr/conf/nfs4server.conf` file as shown (in bold) below to mask the path and show only the name of the volume to the client. Note that the following sample block shows a pseudo path that is different from the exported path.

```
EXPORT
{
    # Export Id (mandatory, each EXPORT must have a unique Export_Id)
    Export_Id = 77;

    # Exported path (mandatory)
    Path = /mapr;

    # Pseudo Path (required for NFS v4)
    Pseudo = /vol1;
    Squash = No_Root_Squash;
```

```

# Required for access (default is None)
# Could use CLIENT blocks instead
Access_Type = RW;

# Security type (krb5,krb5i,krb5p)
SecType = krb5;

# Exporting FSAL
FSAL {
    Name = MAPR;
}
}

```

Configuration for Security

The NFS client to NFS Server can be secured using Kerberos. Before configuring Kerberos to work with MapR, modify the `/opt/mapr/conf/nfs4server.conf` file to specify the security type. For example, modify the `EXPORT` block in the `/opt/mapr/conf/nfs4server.conf` file as shown (in bold) below.

```

EXPORT
{
    # Export Id (mandatory, each EXPORT must have a unique Export_Id)
    Export_Id = 77;

    # Exported path (mandatory)
    Path = /mapr;

    # Pseudo Path (required for NFS v4)
    Pseudo = /vol1;
    Squash = No_Root_Squash;

    # Required for access (default is None)
    # Could use CLIENT blocks instead
    Access_Type = RW;

    # Security type (krb5,krb5i,krb5p)
    SecType = krb5;

    # Exporting FSAL
    FSAL {
        Name = MAPR;
    }
}

```

The NFSv4 server uses the ticket in `/opt/mapr/conf` directory, if it is present, to secure communication between the NFS server and the MapR cluster.

Configuration for Clients

You can add a client block to the NFSv4 server configuration specifying the list of clients to which the export permissions apply. Clients may be specified by hostname, IP address, netgroup, CIDR network address, host name wild card, or simply "*" to apply to all clients. For example:

```

EXPORT
{
    # Export Id (mandatory, each EXPORT must have a unique Export_Id)
    Export_Id = 77;

```

```

# Exported path (mandatory)
Path = /mapr;

# Pseudo Path (required for NFS v4)
Pseudo = /mapr;

# Defining the clients who are allowed to export
CLIENT
{
  # Required for access (default is None)
  Clients=192.168.0.10, 192.168.1.0/8;
  Access_Type = RW;
  Squash = No_root_squash;
  SecType=krb5;
}
# Exporting FSAL
FSAL{
  Name = MAPR;
}
}

```

Configuration for NFS Ganesha Debug Logging

Add the following block in the `/opt/mapr/conf/nfs4server.conf` file.

```

LOG {
  COMPONENTS {
    ALL = DEBUG;
  }
}

```

Default NFSv4 Server Configuration File

NOTE: NFSv4 refers to NFS version 4.1.

The `nfs4server.conf` file is available in `/opt/mapr/conf` directory.

```

LOG
{
  COMPONENTS {
    ALL = INFO;
  }

  FORMAT {
    EPOCH = false;
    CLIENTIP = true;
    HOSTNAME = false;
    PROGNAME = false;
    FILE_NAME = false;
    LINE_NUM = true;
    FUNCTION_NAME = true;
    COMPONENT = false;
    LEVEL = false;
    time_format = syslog_usec;
  }
}

NFSV4
{
  #Delegation is not supported.
  Delegations = false;
}

```

```

#Dirent cache threshold. Use only when readdirplus is true
#Dirent_Cache_Threshold = 128;
}

NFS_CORE_PARAM
{
    Plugins_Dir = /opt/mapr/lib;

    Clustered = false;

    # Max number of results stored in DRC
    DRC_TCP_Size = 16;

    # Expire DRC after 60 seconds (if refcount is zero)
    DRC_TCP_Recycle_Expire_S = 60;

    # Only NFSv4 is supported. showmount will not work
    NFS_Protocols = 4;

    # RQUOTA protocol is not supported
    Enable_RQUOTA = false;

}

```

Configuring NFSv4 Server for Kerberos

Describes how to configure and use NFSv4 on Kerberos.

About this task

NOTE: NFSv4 refers to NFS version 4.1.

You can configure Data Fabric NFSv4 server to use Kerberos-based authentication. Data Fabric supports configuration of [NFSv4 server for Kerberos with Active Directory server](#) and Kerberos with LDAP. You can also configure Data Fabric NFSv4 server to work with [other Kerberos installations](#). Before configuring Data Fabric NFSv4 server for Kerberos, you must have performed the following:

- Installed packages for Kerberos server.
- Installed NFSv4 server. See [Installing NFS for the HPE Data Fabric](#) on page 357 for more information.
- Installed packages for Kerberos client.

NOTE: The steps in this section assume a Linux-based Kerberos environment, and the specific commands for your environment may vary. Please consult with your Kerberos administrator for assistance.

By default, the NFSv4 server is configured to rely on a Kerberos infrastructure. If you don't want or don't have a Kerberos infrastructure, comment out the `SecType` parameter of the `EXPORT` section of the `/opt/mapr/conf/nfs4server.conf` file.

Configure NFSv4 Server for Kerberos with Active Directory Server

About this task

The following procedure describes how to configure the Data Fabric NFSv4 server to work with the Kerberos available with Active Directory server. Before configuring the Data Fabric NFSv4 server, ensure that Active Directory server is installed and all the nodes on the cluster have joined that Active Directory server. The following procedure requires the NFSv4 server to run under user `mapr` and group `maprgrp`.

Procedure

1. In an Active Directory server environment, join the cluster nodes to the Active Directory server. Follow the sample procedure [here](#) or consult with your system administrator for assistance with installing and joining the nodes to Active Directory server.
2. Check if Kerberos tickets for host and NFS service principal are present, by running the following command:

```
# klist
klist: No credentials cache found (filename: /tmp/krb5cc_0)
```

3. Ensure host principal is available by checking to see if existing keys are present on the node. For example, when you run the following command, the output should look similar to the following output for `nfs4ad.com` domain:

```
# klist -kt
Keytab name: FILE:/etc/krb5.keytab
KVNO Timestamp Principal
-----
2 04/10/2018 23:51:24 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
2 04/10/2018 23:51:24 host/ATSQA4-161@NFS4AD.COM
2 04/10/2018 23:51:24 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
2 04/10/2018 23:51:24 host/ATSQA4-161@NFS4AD.COM
2 04/10/2018 23:51:24 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
2 04/10/2018 23:51:24 host/ATSQA4-161@NFS4AD.COM
2 04/10/2018 23:51:25 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
2 04/10/2018 23:51:25 host/ATSQA4-161@NFS4AD.COM
2 04/10/2018 23:51:25 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
2 04/10/2018 23:51:25 host/ATSQA4-161@NFS4AD.COM
2 04/10/2018 23:51:25 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
2 04/10/2018 23:51:25 host/ATSQA4-161@NFS4AD.COM
2 04/10/2018 23:51:25 ATQA4-161$@NFS4AD.COM
2 04/10/2018 23:51:25 ATQA4-161$@NFS4AD.COM
2 04/10/2018 23:51:25 ATQA4-161$@NFS4AD.COM
2 04/10/2018 23:51:25 ATQA4-161$@NFS4AD.COM
2 04/10/2018 23:51:25 ATQA4-161$@NFS4AD.COM
```

4. Generate the host ticket by running the kinit command.

For example:

```
[root@atsqa4-161 ~]# kinit -k ATSQA4-161$
[root@atsqa4-161 ~]# klist
Ticket cache: FILE:/tmp/krb5cc_0
Default principal: ATSQA4-161$@NFS4AD.COM
Valid starting      Expires              Service principal
04/11/2018 03:04:38  04/11/2018 13:04:38  krbtgt/NFS4AD.COM@NFS4AD.COM
        renew until 04/18/2018 03:04:38
```

5. Add NFS service principal entry for the host in the AD server by running the setspn command.

For example, for nfs4ad.com domain, run the following command:

```
C:\Users\Administrator>setspn -A nfs/atsqa4-161.nfs4ad.com mapr
Checking domain DC=nfs4ad,DC=com
Registering ServicePrincipalNames for CN=mapr,CN=Users,DC=nfs4ad,DC=com
        nfs/atsqa4-164.nfs4ad.com
Updated object
```

6. Get the latest service ticket for the host from the AD server by running the kvno command.

For example:

```
# kvno nfs/atsqa4-164.nfs4ad.com@NFS4AD.COM
nfs/atsqa4-164.nfs4ad.com@NFS4AD.COM: kvno = 46
kvno nfs/qa108-43.nfs4ad.com@NFS4AD.COM
```

7. Add entry for NFS service principal key in the Kerberos keytab file, /etc/krb5.keytab:

```
# ktutil
ktutil: addent -password -p nfs/atsqa4-164.nfs4ad.com@NFS4AD.COM -k
46 -e RC4-HMAC
Ex: addent -password -p nfs/qa108-43.nfs4ad.com@NFS4AD.COM -k 46 -e
RC4-HMAC
Password for nfs/atsqa4-164.nfs4ad.com@NFS4AD.COM:
( Give mapr user password i.e nfs4AD123 )
ktutil: l
slot KVNO Principal
-----
    1  46      nfs/atsqa4-164.nfs4ad.com@NFS4AD.COM
ktutil: wkt /etc/krb5.keytab
ktutil: q
```

8. Verify that NFS service principal and host principal are in the `/etc/krb5.keytab` file by running the `klist` command.

For example, for domain `nfs4ad.com`, run the following command and verify the entries in the file:

```
# klist -kt /etc/krb5.keytab
Keytab name: FILE:/etc/krb5.keytab
KVNO Timestamp                Principal
-----
 4 08/01/2018 00:29:21 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
 4 08/01/2018 00:29:21 host/ATSQA4-161@NFS4AD.COM
 4 08/01/2018 00:29:21 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
 4 08/01/2018 00:29:21 host/ATSQA4-161@NFS4AD.COM
 4 08/01/2018 00:29:21 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
 4 08/01/2018 00:29:21 host/ATSQA4-161@NFS4AD.COM
 4 08/01/2018 00:29:21 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
 4 08/01/2018 00:29:21 host/ATSQA4-161@NFS4AD.COM
 4 08/01/2018 00:29:21 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
 4 08/01/2018 00:29:21 host/ATSQA4-161@NFS4AD.COM
 4 08/01/2018 00:29:21 ATSQA4-161$@NFS4AD.COM
 4 08/01/2018 00:29:21 ATSQA4-161$@NFS4AD.COM
 4 08/01/2018 00:29:22 ATSQA4-161$@NFS4AD.COM
 4 08/01/2018 00:29:22 ATSQA4-161$@NFS4AD.COM
 4 08/01/2018 00:29:22 ATSQA4-161$@NFS4AD.COM
 46 08/01/2018 02:58:01 nfs/atsqa4-161.nfs4ad.com@NFS4AD.COM
```

9. Ensure that `/etc/krb5.keytab` file is owned by user `mapr` and if necessary, change ownership to user `mapr`.

For example:

```
[root@qa108-41 ~]# chown mapr:root /etc/krb5.keytab
[root@qa108-41 ~]# ls -l /etc/krb5.keytab
-rw----- 1 mapr root 4175 Jul 22 23:53 /etc/krb5.keytab
```

10. Restart the `rpcgssd` service on the host to establish GSS security contexts.

CentOS

```
service rpcgssd start
```

Ubuntu

```
service gssd restart
```

11. Enable security variable, `SecType`, in the NFSv4 server configuration file at `/opt/mapr/conf/nfs4server.conf`.

For example:

```
# Security type (krb5, krb5i, krb5p)
SecType = krb5;
```

12. Start the NFSv4 server.

For more information, see [Starting, Stopping, and Restarting HPE Data Fabric NFSv4](#) on page 1852.

- 13.** List the shares exported on the server by running `showmount -e` command.

If the protocol is v4 only, the `showmount` command will not return the list of exported NFS shares. Instead, to view the export list, run the following command:

```
/opt/mapr/server/nfs4mgr list-exports
```

- 14.** Ensure that the `list-exports` command runs successfully.

For example:

```
# maprccli nfs4mgmt list-exports
Export Id      Path
30             /mapr
0              /
```

- 15.** (Troubleshooting) Run the following command to restart the services if you see security-related issues.

CentOS

```
maprccli node services -nfs4
stop -nodes `hostname` ; service
rpcgssd restart; sleep 1; service
rpcbind restart ; sleep 1;
service nfs restart ; service
nfs stop ; sleep 2; maprccli
node services -nfs4 start -nodes
`hostname`
```

Ubuntu

```
maprccli node services -nfs4
stop -nodes `hostname` ; service
gssd restart; sleep 1; service
rpcbind restart ; sleep 1; service
nfs-kernel-server restart ; service
nfs-kernel-server stop ; sleep
2; maprccli node services -nfs4
start -nodes `hostname`
```

- 16.** Set up VIPs for the NFSv4 servers:

- a) Add entries for IPs and names of VIPs in the `/etc/hosts` file on the NFSv4 server host first and then on the AD server host.

For example:

```
10.10.88.14 nfsvirtualip1
10.10.88.15 nfsvirtualip2
```

- b) Add NFS service principal for the virtual IP by running the `setspn` command.

For example:

```
C:\Users\Administrator>setspn -A host/nfsvirtualip1 nfsserver
C:\Users\Administrator>setspn -A nfs/nfsvirtualip1 nfsserver

C:\Users\Administrator>setspn -A host/nfsvirtualip2 nfsserver
C:\Users\Administrator>setspn -A nfs/nfsvirtualip2 nfsserver
```

- c) Restart the `rpcgssd` service on the host to re-establish GSS security contexts.

For example:

```
service rpcgssd restart
```

Configuring NFSv4 Server for Other Kerberos Installations

Procedure

1. Configure NFS server for Kerberos.

Consult with your system administrator for assistance with the commands for configuring the NFS server for Kerberos-based authentication. For example, you must do the following:

- Create a service principal with `nfs` as the service name.

For example: `nfs/host.domain.com@REALM`

- Generate a keytab for the NFS service principal, store it in the `/etc/krb5.keytab` file, and set correct permissions on the file.

2. Enable the security variable, `SecType`, in the NFSv4 server configuration file at `/opt/mapr/conf/nfs4server.conf`.

For example:

```
# Security type (krb5,krb5i,krb5p)
SecType = krb5;
```

3. Start the NFSv4 server.

For more information, see [Starting, Stopping, and Restarting HPE Data Fabric NFSv4](#) on page 1852.

4. List the shares exported on the server by running `showmount -e` command.

If the protocol is v4 only, the `showmount` command will not return the list of exported NFS shares. Instead, to view the export list, run the following command:

```
/opt/mapr/server/nfs4mgr list-exports
```

5. Ensure that the `list-exports` command runs successfully.

For example:

```
# maprcli nfs4mgmt list-exports
Export Id      Path
30             /mapr
0              /
```

Configuring NFSv4 Client

Procedure

1. Ensure that NFS client has a `/etc/krb5.keytab` file with a valid principal similar to one of the following: `nfs/<client_fqdn>@<domain>@<REALM>`, `host/<client_fqdn>@<domain>@<REALM>`, or `<HOSTNAME>.$@<REALM>`.

If the principal is not present, create the keytab file with the principal, which will be used to mount the share, for the OS (as mentioned in the OS vendor documentation).

2. Mount the cluster by running the mount command.

For example:

```
mount -t nfs4 -o sec=<security-type> <nfs4-server-hostname>:/
<pseudo-path> <mount-point>
```

For example:

```
# mount -t nfs4 -o sec=krb5 <FQDN>:/mapr /mnt/nfs4mnt
```

3. Generate user ticket for the user to access the mount path.

For example, for user mapr on domain nfs4ad.com, run one of the following commands to generate the ticket:

- ```
kinit mapr@NFS4AD.COM
```

  
 <Enter password>
- ```
echo usr2AD123 | kinit user2@NFS4AD.COM
```

NOTE: You must renew the user ticket before it expires; otherwise, the mount path returns permissions denied error after the ticket expires.

4. (Troubleshooting) Restart the services and mount again to avoid security-related issues.

CentOS

```
service rpcgssd restart; sleep 1;
service rpcbind restart ; sleep 1;
service nfs stop
```

Ubuntu

```
service rpcgssd restart; sleep 1;
service rpcbind restart ; sleep 1;
service nfs stop
```

TROUBLE: Any running IO on NFSv4 mount (with Kerberos) is stuck if the krb5 ticket expires for the current user. The mount point also hangs and becomes inaccessible.

Workaround: Restart the rpcgssd service with the new ticket to make the mount point accessible and re-trigger the IO to proceed.

Configuring NFSv4 Server Without Kerberos

About this task

NOTE: NFSv4 refers to NFS version 4.1.

To start using NFSv4 server without Kerberos, do the following:

Procedure

1. Start the NFSv4 server.

For more information, see [Starting, Stopping, and Restarting HPE Data Fabric NFSv4](#) on page 1852.

2. Verify that the `list-exports` command runs successfully.

For example:

```
# maprcli nfs4mgmt list-exports
Export Id      Path
30             /mapr
0              /
```

3. Mount the cluster by running the `mount` command.

For example:

```
mount -t nfs4 <nfs4-server-hostname>:/<pseudo-path> <mount-point>
```

Starting, Stopping, and Restarting HPE Data Fabric NFSv4

Describes how to start, stop and restart the NFS version 4 service using either the Control System, the CLI, or the REST API.

Starting, Stopping, and Restarting HPE Data Fabric NFSv4 Using the Control System

About this task

NOTE: NFSv4 refers to NFS version 4.1.

See:

- [Starting the Services on the Cluster Using the Control System](#) on page 1401
- [Stopping a Service on the Cluster Using the Control System](#) on page 1402
- [Restarting the Services on the Cluster Using the Control System](#) on page 1403

Starting, Stopping, and Restarting HPE Data Fabric NFSv4 Using the CLI and REST API

About this task

NOTE: On Ubuntu 20, run the following commands before starting NFS4, Else, NFS fails to start, as it cannot find the `jemalloc` library.

```
apt-get install libjemalloc2

ln /usr/lib/x86_64-linux-gnu/libjemalloc.so.2 /opt/mapr/lib/
libjemalloc.so.1
```

CLI

To stop, start, or restart the HPE Data Fabric NFSv4 server, run:

```
maprcli node services -nodes <node
names> -name nfs4 -action stop|start|
restart
```

REST

Send a request of type POST. For example:

```
curl -X
POST 'https://<host>:8443/rest/node/
services?nodes=<nodeNames>&nfs4=stop|
```

```
start|restart' --user
<username>:<password>
```

NOTE: When the NFS server is stopped, the VIPs associated with the server are released, and CLDB attempts to reassign the VIPs to other available NFS servers.

For the complete list of parameters, see [node services](#) on page 2598.

Mounting NFS on a Linux Client

Describes how to mount a NFS server on a Linux client.

About this task

You can manually mount NFS on a Linux client when your system starts up.

NOTE: On nodes running CentOS, use the VIP for mounting because, by default, the mount command will use the physical IP of the node.

Procedure

1. List the NFS shares exported on the server.

For example, run the following command for NFS version 4 servers:

```
maprccli nfs4mgmt list-exports
```

If the NFS protocol is not version 4 only, use the `showmount` command to retrieve the list of exported NFS shares. For example:

```
showmount -e usa-node01
```

2. Mount the cluster using NFS.

For example:

```
mount -t nfs4 -o sec=krb5 usa-node01:/<psuedo_mapr> /mapr
```

Results

TIP: For the best performance, use NFS v4.0.

Use the `vers=4.0` parameter in the mount command. For example:

```
mount -t nfs4 -o sec=krb5,vers=4.0 usa-node01:/<psuedo_mapr> /mapr
```

NOTE: When you mount manually from the command line, the mount point does not persist after a reboot.

Configuring the Linux NFS Client

Describes how to set the optimal number of RPC requests to the NFS server.

About this task

The default RPC requests configuration can negatively impact performance and memory. To avoid performance and memory issues, configure the number of outstanding RPC requests to the NFS server to be 128.

Perform the following steps as the root user on each NFS client machine:

Procedure

1. To enable the configuration to persist after a reboot of the NFS client machine, issue the following commands to create the `sunrpc.conf` file under `/etc/modprobe.d` with the recommended configuration:

```
echo "options sunrpc tcp_slot_table_entries=128" >> /etc/modprobe.d/sunrpc.conf
echo "options sunrpc tcp_max_slot_table_entries=128" >> /etc/modprobe.d/sunrpc.conf
```

2. To enable the configuration to take effect after you remount the NFS client to the NFS for the HPE Data Fabric gateway, issue the following echo commands:

```
echo 128 > /proc/sys/sunrpc/tcp_slot_table_entries
echo 128 > /proc/sys/sunrpc/tcp_max_slot_table_entries
```

3. Remount the NFS client to the NFS for the HPE Data Fabric gateway. For example, the following commands unmount and mount NFS for the HPE Data Fabric assuming that the cluster is mounted at `/mapr`:

```
umount /mapr
mount -o hard,nolock <hostname>:/mapr /mapr
```

NOTE: Failure to configure this property may result in the following error in `/opt/mapr/logs/nfsserver.log`:

```
ERROR nfsserver[38960] fs/nfsd/requesthandle.cc:791 0.0.0.0[0]
cannot allocate more OncRpcContexts: [numDropped=2556001]
dropping connection from nfsc=10.13.64.225:0
```

TIP: For CentOS, after the reboot of the node, if the `/proc/sys/sunrpc` directory is not available or if `rpcidmapd` is not running, start the `rpcidmapd` service using the following command:

```
service rpcidmapd start
```

Advisory Locking in NFS v4

Explains NFS v4 support for Advisory Locking.

Data Fabric NFS v4 service includes support for (advisory) file locking. Data Fabric keeps track of the locks on a file in the NFS for the Data Fabric gateway, but does not prevent a client process from writing to a file that is locked by another process. The locks are not shared with other NFS for the Data Fabric gateways. Since the locks are enforced locally, it is the responsibility of the client process to check for write locks on a file before attempting to perform write operations on the file.

To ensure that a file is locked and not available for changes by other processes and to ensure that the lock on a file by a process is honored by other processes, add a program similar to the following for the process.

Sample Program Description

The following program demonstrates how to open a file, check if the file has a write lock, and wait if another process currently has locked the file.

Before running this application, ensure that you have access to a cluster running file system.

Opens a file

```
if (argc > 1) {
    int fd
    = open(argv[1],
    O_WRONLY);
    if(fd == -1)
    {
        printf("Unable
        to open the
        file\n");
        exit(1);
    }
}
```

Checks if the file is locked for a write operation

```
lock.l_type
= F_WRLCK;
lock.l_start
= 0;

lock.l_whence =
SEEK_SET;
lock.l_len =
0;
lock.l_pid =
getpid();
```

Gets lock, else waits

```
int ret
= fcntl(fd,
F_SETLKW,
&lock);

printf("Return
value of
fcntl:%d\n",ret);
if(ret==0) {
    while (1) {

scanf("%c",
NULL);
    }
}
```

Sample Program Code

```
#include <stdio.h>
#include <fcntl.h>

int main(int argc, char **argv) {
    if (argc > 1) {
        int fd = open(argv[1], O_WRONLY);
        if(fd == -1) {
            printf("Unable to open the
            file\n");
            exit(1);
        }
        static struct flock lock;
```

```

lock.l_type = F_WRLCK;
lock.l_start = 0;
lock.l_whence = SEEK_SET;
lock.l_len = 0;
lock.l_pid = getpid();

int ret = fcntl(fd, F_SETLKW,
&lock);
printf("Return value of
fcntl:%d\n",ret);
if(ret==0) {
    while (1) {
        scanf("%c", NULL);
    }
}
}
}

```

NFSv4 Troubleshooting

NOTE: NFSv4 refers to NFS version 4.1.

Unable to start the service:

If you or the warden is unable to restart the NFS service, do the following:

1. Review the warden logs (in \$MAPR_HOME/logs/warden.log file) to determine when the [NFSv4 Service Alarm](#) on page 3406 was raised.

2. Review the following NFSv4 server logs in \$MAPR_HOME/logs/nfs4/nfs4server.log-0 and \$MAPR_HOME/logs/nfs4/fsal.log-0, and other logs under \$MAPR_HOME/logs/nfs4 on the node where the service went down to determine the cause for the error.

The following example logs show some common causes for NFSv4 service shutting down such as license not present or an issue in the configuration.

```

3. Take corrective action to rectify the cause for the error.

Viewing the List of NFS Servers

Explains how to view the list of NFS servers using the Control System.

About this task

Procedure

- Log in to the Control System and go to the [service information page](#) for CLDB.

The **Active NFS Servers** section displays the following:

Column Name	Column Description
Server ID-HEX	The server's ID in hexadecimal notation.
Server ID	The server's ID in decimal notation.
Host Port	The IP address of the NFS server host.

Column Name	Column Description
Hostname	The hostname of the NFS server host.
Last heartbeat	The timestamp for the last received heartbeat.
State	The status of the NFS server. Value can be: <ul style="list-style-type: none"> Active

Handling Heavy Write Loads on Red Hat Enterprise Linux

Describes a fix to mitigate resource contention between NFS Clients and the NFS Server on Red Hat Linux.

If you are operating on RHEL and have a heavy NFS write load, you might experience resource contention between the NFS client and the NFS server. This resource contention can cause the NFS server to be unresponsive. To avoid this potential problem, try one of following approaches. These approaches work on all versions of Red Hat (5.x, 6.x and 7.x).

- Edit `/etc/sysctl.conf` and apply these settings on each NFS server:

```
vm.dirty_ratio=10
vm.dirty_background_ratio=5
```

Reboot the server so the changes will take effect. To make the settings take effect immediately, issue the `echo` command as shown:

```
% echo 10 > /proc/sys/vm/dirty_ratio
% echo 5 > /proc/sys/vm/dirty_background_ratio
```

- Separate the NFS client from the NFS server so they do not compete for memory on the same system.

Configure NFS Write Performance

Describes how to set the optimal value for outstanding Remote Procedure Call (RPC) requests to the NFS server.

The default Remote Procedure Call (RPC) requests configuration can negatively impact performance and memory. To avoid performance and memory issues, configure the number of outstanding RPC requests to the NFS server to be 128, for optimal performance. The NFS client uses this value to determine when to send requests to the NFS server, along with the number of parallel requests to send.

- If the value is too small, the NFS client does not send many parallel requests. This scenario results in decreased performance.
- If the value is too high, the NFS client sends a lot of parallel requests, but the NFS server discards some requests, as it has a limit on the number of requests it can handle. This scenario causes the NFS client to resend the requests, and negatively affects performance.

The kernel tunable value `sunrpc.tcp_slot_table_entries` represents the number of simultaneous RPC requests. The default value of this tunable is 16 (on Red Hat versions prior to version 6.3). On Red Hat versions 6.3 and above, the default value of this tunable is set at 65536. Increasing or decreasing this value to 128 (depending on the Red Hat version in use), may improve write speeds. Use the command `sysctl -w sunrpc.tcp_slot_table_entries=128` to set the value. Add an entry to your `sysctl.conf` file to make the setting persist across reboots.

Perform the following steps as the root user, on each NFS client machine:

1. Issue the following commands to create the `sunrpc.conf` file under `/etc/modprobe.d` with the recommended configuration. These commands enable the configuration to persist after a reboot of the NFS client machine.

```
echo "options sunrpc tcp_slot_table_entries=128" >> /etc/modprobe.d/sunrpc.conf
echo "options sunrpc tcp_max_slot_table_entries=128" >> /etc/modprobe.d/sunrpc.conf
```

2. Issue the following `echo` commands. These commands enable the configuration to take effect after you remount the NFS client to the NFS for the HPE Data Fabric gateway.

```
echo 128 > /proc/sys/sunrpc/tcp_slot_table_entries
echo 128 > /proc/sys/sunrpc/tcp_max_slot_table_entries
```

3. Remount the NFS client to the NFS for the HPE Data Fabric gateway. Mount the Data Fabric NFS server with a `rsize` and `wsize` of 128K, as this value significantly cuts down NFS server requests for a given transfer, and improves the overall performance. For example, the following commands unmount and mount the NFS server, assuming that the cluster is mounted at `/mapr`.

```
umount /mapr
mount -o nolock,rsize=131072,wsize=131072 <hostname>:/mapr /mapr
```

4. After rebooting the node, if the `/proc/sys/sunrpc` directory is not available, or if `rpcidmapd` is not running, start the `rpcidmapd` service, using the following command: `service rpcidmapd start`.

Failure to set this tunable to an optimum value, may result in the following error in the `/opt/mapr/logs/nfsserver.log` file:

```
ERROR nfsserver[38960] fs/nfsd/requesthandle.cc:791 0.0.0.0[0] cannot
allocate more OncRpcContexts: [numDropped=2556001] dropping connection from
nfsc=10.13.64.225:0
```

NFS for the HPE Data Fabric write performance varies between different Linux distributions. The recommended value of this tunable may have no effect, or even a negative effect on your particular cluster.

Adjusting NFS Memory Settings

The memory allocated to each Data Fabric service is specified in the `/opt/mapr/conf/warden.conf` file, which Data Fabric automatically configures based on the physical memory available on the node. You can adjust the minimum and maximum memory used for NFS, as well as the percentage of the heap that it tries to use, by setting the `percent`, `max`, and `min` parameters in the `warden.conf` file on each NFS node. Example:

```
...
service.command.nfs.heapsize.percent=3
service.command.nfs.heapsize.max=1000
service.command.nfs.heapsize.min=64
...
```

The percentages need not add up to 100; in fact, you can use less than the full heap by setting the `heapsize.percent` parameters for all services to add up to less than 100% of the heap size. In general, you should not need to adjust the memory settings for individual services, unless you see specific memory-related problems occurring.

Running NFS on a Non-standard Port

Procedure

1. To run NFS on an arbitrary port, modify the following line in `warden.conf`:

```
service.command.nfs.start=/etc/init.d/mapr-nfsserver start
```

Add `-p <portnumber>` to the end of the line, as in the following example:

```
service.command.nfs.start=/etc/init.d/mapr-nfsserver start -p 12345
```

2. After modifying `warden.conf`, restart the Data Fabric NFS server by issuing the following command:

```
maprccli node services -nodes <nodename> -nfs restart
```

3. You can verify the port change with the `rpcinfo -p localhost` command.

WARNING: MapR uses version 3 of the NFS protocol. NFS version 4 bypasses the port mapper and attempts to connect to the default port only. If you are running NFS on a non-standard port, mounts from NFS version 4 clients time out. Use the `-o nfsvers=3` option to specify NFS version 3.

Enabling Debug Logging for NFS Using the CLI

About this task

Debug-level logging is available to help you isolate and identify NFS-related issues.

NOTE: NFSv4 refers to NFS version 4.1.

Enabling Debug Logging for NFSv3

Procedure

1. To enable logging at the debug level, enter this command at the command line:

```
maprccli trace setlevel -port 9998 -level debug
```

where `-port 9998` indicates NFS.

WARNING: The debug log level provides much more information than the default log level of `info`.

2. In default mode, information is logged to a buffer and dumped periodically. To display information immediately instead, enable continuous mode by entering:

```
maprcli trace setmode -port 9998 -mode continuous
```

Sample log output from an `ls` command is shown here:

From `/opt/mapr/logs/nfsserver.log`:

```

```

The log shows every operation sent to and received from an NFS client.

3. To return to the default log level and log mode, enter:

```

maprcli trace setlevel -port 9998 -level default
maprcli trace setmode -mode default

```

Enable Debug Logging for NFSv4

Procedure

- 1. Modify `core-site.xml` file to add the following:

```
<property>
  <name>fs.mapr.trace</name>
  <value>DEBUG</value>
  <description> </description>
</property>
```

- 2. Save and close the file.

Example

Run the `/opt/mapr/server/nfs4mgr` command for debugging NFS Ganesha.

Unmounting the Data Fabric Cluster from the Command-Line

Procedure

- To unmount the Data Fabric cluster, run the `umount` command.
For example, to unmount the cluster in `/mapr`, run the following command:

```
umount /mapr
```

If a process is busy on the mount point, the `umount` command will fail. To unmount the cluster after the process completes, run the following command:

```
umount -l /mapr
```

Managing HPE Data Fabric POSIX Clients

Provides a brief synopsis of HPE Data Fabric POSIX clients.

The HPE Data Fabric POSIX clients allow app servers, web servers, and other client nodes and apps to read and write data directly and securely to a HPE Data Fabric cluster. The following topics describe the steps for configuring and managing loopback NFS POSIX and FUSE-based POSIX clients.

Apart from the clients that are EOL, all others are supported. However, newer clients might have features that may not be supported in older clients.

Difference between the POSIX loopback NFS client and the FUSE-based POSIX Basic and Platinum clients

The following table summarizes the differences between the POSIX loopback NFS client and the FUSE-based POSIX Basic and Platinum clients:

	HPE Data Fabric POSIX Loopback NFS Client	HPE Data Fabric FUSE-based POSIX Basic/Platinum Client
Throughput	<ul style="list-style-type: none">• 500MB/s for remote read/write• 1G/s for local read/write	Greater than 2G/s for remote and local read/write
Client OS	Supported Linux and Ubuntu distributions only.	

	HPE Data Fabric POSIX Loopback NFS Client	HPE Data Fabric FUSE-based POSIX Basic/Platinum Client
Installs On Node Type	<ul style="list-style-type: none"> Client node Cluster node 	
Access to Cluster	Must have direct network access to all HPE Data Fabric cluster nodes.	Must have direct network access to all HPE Data Fabric cluster nodes. However, each client only supports up to 16 clusters.
Connection to File System	<ul style="list-style-type: none"> Proxied on host to regular HPE Data Fabric client traffic Direct, no NFS for the HPE Data Fabric gateway No single point of failure 	
Security	Fully secured.	
Caching	Buffered writes are cached in the kernel.	Buffered writes are cached (only in kernel >= 3.15) if writeback option is enabled.

HPE Data Fabric loopbacknfs POSIX Client

Explains the differences between the HPE Data Fabric POSIX client and the Linux native NFS client.

The HPE Data Fabric POSIX Client feature allows app servers, web servers, and other client nodes and apps to read and write directly to a HPE Data Fabric cluster. Starting with the 4.0.2 release, HPE Data Fabric provides single-user loopbacknfs licenses that give access to one or more clusters.

The table below summarizes the differences between the basic Linux OS NFS client and the HPE Data Fabric POSIX client:

	Linux OS Client	HPE Data Fabric POSIX Client
Client OS	<ul style="list-style-type: none"> Supported Linux distributions and desktop systems (Mac OS X and Windows) 	<ul style="list-style-type: none"> Supported Linux distributions only No version for Mac OS X
Installs On Node Type	<ul style="list-style-type: none"> Client node - not part of the HPE Data Fabric cluster No mapr-fileserver or other Hadoop services 	<ul style="list-style-type: none"> Client node Cluster node
Access to Cluster	<ul style="list-style-type: none"> Must have direct network access to NFS Gateways. 	<ul style="list-style-type: none"> Must have direct network access to all HPE Data Fabric cluster nodes
Supported Interfaces	<ul style="list-style-type: none"> POSIX-NFS 	<ul style="list-style-type: none"> POSIX-NFS
Connection to File System	<ul style="list-style-type: none"> Point to point Via an NFS gateway Single point of failure 	<ul style="list-style-type: none"> Proxied on host to regular HPE Data Fabric client traffic Direct, no NFS gateway No single point of failure
Security	<ul style="list-style-type: none"> Link to NFS gateway is insecure 	<ul style="list-style-type: none"> Fully secured

The Linux OS NFS client must go through an NFS gateway, the link to the gateway is not secured, and transmitted data is not compressed.

The following diagram illustrates how the HPE Data Fabric POSIX client (mapr - loopbacknfs) works, in comparison with the Linux OS NFS client (left).

The instructions on this page are for the HPE Data Fabric POSIX client. For instructions on setting up NFS on a HPE Data Fabric cluster, see [Managing the HPE Data Fabric NFS Service](#) on page 1810.

The table below summarizes the differences in the HPE Data Fabric POSIX client deployment behavior when installed with a HPE Data Fabric cluster where security is disabled or enabled:

	Cluster Security Disabled	Cluster Security Enabled
Client Node	<ul style="list-style-type: none"> HPE Data Fabric cluster looks exactly like network attached storage (NAS) POSIX permissions are enforced 	<ul style="list-style-type: none"> Single-user authentication Write access is supported only for applications with UID matching authenticated user

	Cluster Security Disabled	Cluster Security Enabled
Cluster Node	<ul style="list-style-type: none"> • HPE Data Fabric cluster looks exactly like NAS • POSIX permissions are enforced 	<ul style="list-style-type: none"> • Secure cluster access is key • Best Practice: Use ticket from <i>mapr</i> user

Specifying Environment Variables

Explains how to set environment variables on a client node.

About this task

Some of the environment variables defined on the servers for the HPE Data Fabric cluster must be defined with the same values on the client. You can add environment variables directly to the startup script, or create a local `env.sh` file in `/usr/local/mapr-loopbacknfs/conf`. You cannot simply copy the `env.sh` file from a server node in the cluster because the `MAPR_HOME` setting would be different.

The `loopbacknfs` service can run either on file server nodes or external edge nodes.

loopbacknfs running on file server node:

- If you want `loopbacknfs` to avoid using the internal IP address that has been set by using the `MAPR_SUBNETS` (usually set through `env_override.sh/env.sh` which is applied across all processes running in a machine), mark `NFS_LOOPBACK_HONOUR_SUBNETS` as `false`.

loopbacknfs running on edge node:

- When `MAPR_SUBNETS` environment variable is set on edge nodes, the intention is to divert the traffic through the intended IP address, instead of all. Whether the given subnet is to be used or not is determined by the value of the `NFS_LOOPBACK_HONOUR_SUBNETS` environment variable.

Re-registration of loopbacknfs service

- The process of re-registration of `loopbacknfs` with CLDB when using or honoring subnets is done as follows:
 - If there is change in device address, but device address is out of the subnet, `loopbacknfs` does not re-register.
 - If there is change in device address and if there are no subnets at all, `loopbacknfs` reregisters.

Complete the following steps to specify environment variables:

Procedure

1. On a server node in the HPE Data Fabric cluster, locate the `env.sh` and `env_override.sh` files in the `/opt/mapr/conf` directory. If the `env_override.sh` file is not present, use the `env.sh` file. For more information about these files, see [About env_override.sh](#) on page 3467.
2. Retrieve the values for `MAPR_SUBNETS` and `JAVA_HOME` from the server files and clone them to `/usr/local/mapr-loopbacknfs/conf/env.sh` on the client node.
3. (Optional) Set the `NFS_LOOPBACK_HONOUR_SUBNETS` environment variable to avoid re-registration whenever there is a change in any network interface. The value can be:
 - `true` to consider the `MAPR_SUBNETS` while registering with CLDB. If set to `true`, re-registration does not happen when there is a change in any network interface with IP that is not in the given `MAPR_SUBNETS`. If there is a change in the device address, but the device address is outside of subnet, the re-registration does not happen. Re-registration happens if there are no subnets at all and the device address has changed.

- `false` to ignore the `MAPR_SUBNETS`. If set to `false`, re-registration happens when there is a change in any network interface.

For example:

```
# export NFS_LOOPBACK_HONOUR_SUBNETS=true
# export MAPR_SUBNETS=10.10.104.0/24

# env | grep SUBNET
NFS_LOOPBACK_HONOUR_SUBNETS=true
MAPR_SUBNETS=10.10.105.0/24,10.10.104.0/24
```

4. Change the `JAVA_HOME` setting to point to the location where Java is installed on the client.
5. Add the following lines to the client node `env.sh` file:

```
export MAPR_HOME=/usr/local/mapr-loopbacknfs
export MAPR_TICKETFILE_LOCATION=<MAPR user ticket path>
```

NOTE: To allow impersonation, set the value for `MAPR_TICKETFILE_LOCATION` to the path to the mapr user ticket.

6. Save and close the `env.sh` file.
7. Restart the `loopbacknfs` service for the changes to take effect.

Copying Configuration Files from a Server Node

About this task

Settings in the `nfsserver.conf` and `mapr-clusters.conf` files on server nodes in the Data Fabric cluster are also needed by the POSIX client. Complete the following steps to copy configuration files from a server node:

Procedure

1. On a server node in the Data Fabric cluster, locate the `nfsserver.conf` and `mapr-clusters.conf` files in the `/opt/mapr/conf/` directory.
2. Copy both of those files to the `/usr/local/mapr-loopbacknfs/conf/` directory on the client machine.

Starting the mapr-loopbacknfs Service to Access a Cluster

Describes the prerequisites and the process of starting the `mapr-loopbacknfs` service to access a secure cluster.

The following instructions explain how to start the `loopbacknfs` service so you can access either a non-secure or secure cluster.

To access multiple clusters, ensure that the first cluster that you configure is a HPE Data Fabric cluster, with available POSIX client licenses.

Prerequisites for accessing a secure cluster:

- Ensure that the stock Linux NFS service is not running. Linux NFS and HPE Data Fabric NFS cannot run concurrently.
- Disable the lock manager (`nlockmgr`).

- Check that the `rpcbind` service is running on RHEL and CentOS v6.0 and higher. You can use the command `ps ax | grep rpcbind` to check.
- Check that the `portmapper` service is running on RHEL and CentOS v5.x and lower, and on Ubuntu and SLES. You can use the command `ps ax | grep portmap` to check.
- Make sure you have applied a Community Edition (M3) license or an Enterprise Edition (M5) license (paid or trial) to the cluster. See [Adding a License](#) on page 1339.
- Enable security for the cluster. See [Enabling Wire-level Security](#) on page 2067 and [Disabling Wire-level Security](#) on page 2069 wire-level security.

NOTE: Securing the cluster so that only one user can have secure access provides tight control over cluster access, but it also means that any user on the client who is able to read the generated ticket has read access to all data in the cluster.

Start the `mapr-loopbacknfs` service and mount the volume

Complete the following steps from your client node, except where noted, to start the `mapr-loopbacknfs` service and mount the volume:

1. Use the `scp` utility to copy the `mapr-clusters.conf` file from any cluster node to the `/usr/local/mapr-loopbacknfs/conf/` directory on the loopbacknfs client node.

```
scp /opt/mapr/conf/mapr-clusters.conf root@<client_ip>:/usr/local/
mapr-loopbacknfs/conf/mapr-clusters.conf
```

2. Generate a user ticket. See [Generating a HPE Data Fabric User Ticket](#) on page 2103 for instructions. If you do not have your HPE Data Fabric user ticket with full control [ACL](#) authorization on the cluster, you must have a cluster administrator do the following for you.
 - a. In the HPE Data Fabric cluster, navigate to the cluster node to which you want to connect.
 - b. Log on to the cluster node as an administrator by running the `maprlogin password` command.
 - c. Run the `maprlogin generateticket -type service -user <user> -duration 365:0:0 -out /tmp/nfsticket` command to generate the user ticket.

If the service ticket expires, the POSIX client:

- Automatically uses the renewed service ticket without requiring a restart, if the ticket is replaced before expiration (that is, ticket expiry time + grace period of 55 minutes). If the ticket is replaced after expiration, the POSIX loopbacknfs client does not refresh the ticket as the mount becomes stale.
 - Allows impersonation if a service ticket is replaced before ticket expiration (that is, ticket expiry time + grace period of 55 minutes) with a `servicewithimpersonation` ticket.
 - Honors all changes in the user IDs/group IDs of the renewed ticket.
3. Copy the user ticket file `/tmp/nfsticket` from the cluster node where you generated it to the `/usr/local/mapr-loopbacknfs/conf` directory on the client node running the HPE Data Fabric POSIX client.

NOTE: Since the NFS server runs based on a single user's ticket, it can act on behalf of only one user. Therefore, the UID or GID associated with the ticket must match the UID or GID of any user who accesses the NFS server through the HPE Data Fabric POSIX Client.

4. Create the `/usr/local/mapr-loopbacknfs/conf/env.sh` file with the 644 permissions (read permission for all users and write permission for owner) on the file, if the file is not already present. Add the path of the maprticket path file location to `env.sh`.

```
export MAPR_TICKETFILE_LOCATION=/usr/local/mapr-loopbacknfs/conf/
nfsticket
```

5. Start the `mapr-loopbacknfs` service from the command line.

```
service mapr-loopbacknfs start
```

6. Create a mount point at `/mapr` and mount the client node to it.

```
mkdir /mapr
mount localhost:/mapr /mapr
```

7. Automate the mounting of the volume with every launch of the `mapr-loopbacknfs` service. On the POSIX client node, create `/usr/local/mapr-loopbacknfs/conf/mapr_fstab` and add the following line:

```
localhost:/mapr /mapr hard,noexec
```

Securing the Mountpoint

About this task

POSIX permissions are the only limitation on read access by the Data Fabric POSIX client, whether the cluster connected to has security enabled or disabled. By securing the mountpoint, you can limit access to a single user.

Complete the following steps to secure the mountpoint:

Procedure

1. On the client system, create `/mapr/<clustername>`:

```
mkdir -p /mapr/<clustername>
```

2. Set ownership and permissions:

```
chown user1:<posix_user> /mapr
chmod 700 /mapr
```

3. Mount the cluster:

```
mount localhost:/mapr/<clustername> /mapr/<clustername>
```

Now only the `<posix_user>` can access the cluster with the POSIX client.

Registering a POSIX Client with Additional Clusters

The first time you start the `loopbacknfs` service, you edit the `mapr-loopbacknfs` init script by defining the `CLUSTER_NAME` and `CLDB_IPS` variables, then run the script. These actions update the `/usr/local/mapr-loopbacknfs/conf/mapr-clusters.conf` file.

However, when you want to register a client with a new cluster or an additional cluster, you must add entries directly to the `/usr/local/mapr-loopbacknfs/conf/mapr-clusters.conf` file. Editing the `mapr-loopbacknfs` script and restarting the `loopbacknfs` service does not update the `mapr-clusters.conf` file.

Configuring the HPE Data Fabric POSIX Client

Explains how to set the number of RPC requests that POSIX clients send to a cluster.

About this task

The default RPC requests configuration can negatively impact performance and memory. To avoid performance and memory issues, configure the number of outstanding RPC requests to the cluster to be 128.

Perform the following steps as the root user on each POSIX client machine:

Procedure

1. Issue the following commands to create the `sunrpc.conf` file under `/etc/modprobe.d` with the recommended configuration:

```
echo "options sunrpc tcp_slot_table_entries=128" >> /etc/modprobe.d/sunrpc.conf
echo "options sunrpc tcp_max_slot_table_entries=128" >> /etc/modprobe.d/sunrpc.conf
```

These commands enable the configuration to persist after a reboot of the NFS client machine.

2. Issue the following echo commands:

```
echo 128 > /proc/sys/sunrpc/tcp_slot_table_entries
echo 128 > /proc/sys/sunrpc/tcp_max_slot_table_entries
```

The commands enable the configuration to take effect after you remount the POSIX client to the HPE Data Fabric cluster.

3. Remount the POSIX client to the HPE Data Fabric cluster. For example, the following commands unmount and mount the NFS assuming that the cluster is mounted at `/mapr`:

```
umount /mapr
mount -o hard,noexec 127.0.0.1:/mapr /mapr
```

NOTE: Failure to configure this property may result in the following error in `/usr/local/mapr-loopbacknfs/log`: `ERROR nfsserver[38960] fs/nfsd/requesthandle.cc:791 0.0.0.0[0] cannot allocate more OncRpcContexts: [numDropped=2556001] dropping connection from nfsc=10.13.64.225:0`

CentOS Troubleshooting Tip

After the reboot of the node, if the `/proc/sys/sunrpc` directory is not available, or if `rpcidmapd` is not running, start the `rpcidmapd` service using the following command: `service rpcidmapd start`.

Verifying Data Fabric POSIX Client Licenses

Use the Control System, to check how many Data Fabric POSIX client licenses are available and being used.

About this task

Procedure

- 1. Log in to the Control System and click **Admin > Cluster Settings**.
- 2. Look at the **LICENSES** pane for the number of POSIX Client nodes that are available and currently being used.

Managing the mapr-loopbacknfs Service

Explains how to start/stop and manage the loopbacknfs service from the command line.

To manually start or stop the service:

```
service mapr-loopbacknfs [start|stop]
```

To have the service start automatically when the OS starts up:

```
systemctl enable mapr-loopbacknfs
```

To monitor the service:

```
service mapr-loopbacknfs status
showmount -e localhost
```

The showmount command displays:

```
Export list for <host>
/mapr 127.0.0.1
/mapr/<clustername> 127.0.0.1
```

Setting Up Aliases for NFS Exports

About this task

When provisioning file system for various tenants, you can set up an alias for the path in file system, rather than exporting the whole path, to mask the path from the users. Once the alias is set up, users will not be able to access or mount the path in file system.

Aliases can be set up for the cluster, volume, and directory, but not for the root of the path in file system (/mapr). To set up an alias for a path in file system:

Procedure

- 1. Open the NFS exports file in /opt/mapr/conf/ directory.
- 2. Specify the alias name for the mount path using the following syntax:

```
<path in MFS> /<alias name> <options>
```

Here:

<path in MFS>	Refers to the file system mount path. If this points to a: <ul style="list-style-type: none">• Volume, the user can access the snapshots associated with the volume.• Directory, the user cannot access the snapshots.
/<alias name>	Refers to the alias name to use. If there are duplicate aliases in the file, the last entry will take effect and all other duplicate entries will be ignored. If the alias name is not specified, the path in file system will be exported.

<options>	The list of available/supported options.
-----------	--

For example, suppose a file system mount path of `/mapr/samplecluster/samplevolume` for tenant `samplecustomer`. To set up an alias, add the following to the exports file:

```
/mapr/samplecluster/samplevolume /samplecustomer (rw)
```

For example, to export a certain cluster, volume, or a subdirectory as an alias, comment out `/mapr` and add the following:

```
/mapr/clustername /alias1 (rw)
/mapr/clustername/vol /alias2 (rw)
/mapr/clustername/vol/dir /alias3 (rw)
```

NOTE: Only the alias will be visible/exposed to the NFS client.

3. Run the following command for the file changes to take effect:

```
/opt/mapr/bin/maprcli nfsmgmt refreshexports
```

4. Run the following command to export the path:

```
mount -t nfs nfsServer:/<alias_name> /localpath
```

Run this command once for each entry in the file.

What to do next

The same export rules must be set up on all the NFS servers in the cluster to ensure that in the event of a node failure, the same aliases work with VIP failover.

Troubleshooting mapr-loopbacknfs Service Issues

Describes solutions for mapr-loopbacknfs issues.

To debug authentication issues, follow these steps:

1. If you receive a standard error (stderr):
 - Make sure `rpcinfo/portmap` is installed and/or run `service portmap start`.
 - Run `service rpcbind restart`.
2. Examine the log files for error messages:

```
/usr/local/mapr-loopbacknfs/logs/loopbacknfs.log
/usr/local/mapr-loopbacknfs/logs/mount_local_fs.log
```

Error messages in `loopbacknfs.log` file:

Error Message	Solution
Refresh User tickets failed as security layer could not be initialized with user ticket /tmp/maprticket_0	Unset <code>MAPR_TICKETFILE_LOCATION</code> in <code>initscripts/mapr-loopbacknfs</code> .

Error Message	Solution
exiting: license only allows 10 NFS/mfs server(s), currently alive=10	If you have multiple clusters listed in the <code>mapr-clusters.conf</code> file on the client, make sure the first one listed is a MapR 4.0.2 or later cluster. If that is not the problem, you will probably need to purchase additional licenses, or reduce number of installations of the <code>mapr-loopbacknfs</code> service.
mount.nfs: Protocol not supported	The NFS directory with <code>mapr-loopbacknfs</code> is already mounted.

3. Verify that settings in configuration files are correct.

- For all clusters: `/usr/local/mapr-loopbacknfs/conf/mapr-clusters.conf`
- For secure clusters: `MAPR_TICKETFILE_LOCATION`

4. Check for “stale” mounts.

- The `mount_local_fs.pl` script can cause the `initscript` wrapper to force unmounts of the mounted file systems.
- Always check for stale mounts after stopping the service:
 - `df -k` should return instantly.
 - Use `umount -f <mount_point>` to force the unmount.
 - Use `ps -ef | grep mount_local` to confirm that the script is not stuck.

HPE Data Fabric FUSE-Based POSIX Client

Provides a brief description of the FUSE-based POSIX client.

The HPE Data Fabric FUSE-based POSIX client (either *mapr-posix-client-basic* or *mapr-posix-client-platinum*) allows app servers, web servers, and other client nodes and apps to read and write data directly and securely to a HPE Data Fabric cluster like a Linux filesystem.

The same HPE Data Fabric client can access both secure and nonsecure clusters; however, a HPE Data Fabric client that is configured to access a secure cluster can access a nonsecure cluster only if these conditions are met:

1. The secure cluster must be listed in the `mapr-clusters.conf` file.
2. A user must obtain a ticket for the secure cluster even if the user wants to access only the nonsecure cluster.

The FUSE-based HPE Data Fabric POSIX client runs as a userspace process to connect to one or more HPE Data Fabric clusters. The necessary FUSE (Filesystem in Userspace) library (`libfuse`) is bundled with the POSIX client package. With the installation of the POSIX client package, the HPE Data Fabric POSIX client performs operations such as read and write on the filesystem exposed by FUSE. The following diagram illustrates how the HPE Data Fabric FUSE-based POSIX client works.

Example of Mounting FUSE

This example shows you how to mount FUSE and perform operations as a regular user.

The following example is a quick introduction to mounting FUSE and accessing the mount point as a regular user.

Assume that you have a mount point `/mapr` that you want to mount on FUSE and access as user `kate`.

Perform the following steps:

1. Create the user `kate`: Run

```
adduser kate
```

2. Generate a ticket with impersonation as user `kate`. You will use this ticket to mount and access FUSE. Run:

```
maprlogin generateticket -type servicewithimpersonation -user  
kate -out /var/tmp/sample_ticket
```

NOTE: For more information on generating a ticket with impersonation, see [How Impersonation Works](#) on page 2215 and [Generating a Service with Impersonation Ticket](#) on page 2104

3. Edit the `/opt/mapr/conf/fuse.conf` file and set `fuse.ticketfile.location=/var/tmp/sample_ticket`
4. The mount point `/mapr` is already set in the `fuse.conf` file.

NOTE: Change `fuse.mount.point=/mapr` if your mount point is different from `/mapr`.

5. Create the `/mapr` directory. Run:

```
mkdir /mapr
```

6. Start the MapR FUSE POSIX client, either *basic* or *platinum* as per your licence. For example:

```
service mapr-posix-client-basic start
```

The `/mapr` directory is now mounted on FUSE. You can perform all operations on `/mapr/` as the user `kate`.

Related concepts

[Configuring the HPE Data Fabric FUSE-Based POSIX Client](#) on page 1876

Lists FUSE configuration parameters.

[Managing the FUSE-Based POSIX Client](#) on page 1892

Describes how to use the FUSE-based POSIX client.

[How Impersonation Works](#) on page 2215

Introduces impersonation functionality, limitations, and core requirements.

[Generating a Service with Impersonation Ticket](#) on page 2104

Configuring the HPE Data Fabric FUSE-Based POSIX Client

Lists FUSE configuration parameters.

FUSE Parameters

You can set the POSIX client configuration values in the `/opt/mapr/conf/fuse.conf` file. After [installing the FUSE-based POSIX client](#), you can edit the configuration file to define the values for the following parameters and save the file.

To retrieve the list of configuration parameters, run the following command:

```
/opt/mapr/bin/posix-client-* --help
```

Here `*` refers to the basic or platinum client package installed on the system. If necessary, set the shared `LD_LIBRARY_PATH` environment variable to run the `help` option with the command. For example:

```
export LD_LIBRARY_PATH=/usr/lib/jvm/
java-1.7.0-openjdk-1.7.0.79.x86_64/jre/lib/amd64/server:/opt/mapr/lib
```

NOTE: The HPE Data Fabric FUSE-based POSIX clients support only the configuration parameters in the `fuse.conf` file. All other FUSE configuration parameters are not supported. For more information on the non-mapr configuration parameters, refer to FUSE [documentation](#).

`fuse.access.type`

Default Value: `rw`

Sets the type of access on the mount point. Value can be:

- `ro` — Read only
- `rw` — Read and write

`fuse.affinity`

Default Value: `0` (Disabled)

Specifies whether to enable (1) or disable (0) NUMA affinity. If enabled, sets the NUMA affinity for the POSIX client.

`fuse.allow.other`

Default Value: `1`

Allow other users to access the mount point. Value can be one of:

- `0` - do not allow other users

- 1 - allow other users

Set this to 1 if the root user starts the FUSE service. Set to 0 or comment out this parameter if a non-root user starts the FUSE service. If set to 1, also add the `user_allow_other` parameter to the `/etc/fuse.conf` file.

`fuse.asyncdirect.io`

Default Value: 1

Specifies whether to enable asynchronous direct IO. Value can be one of:

- 0 - disable
- 1 - enable

`fuse.attr.timeout`

Default Value: 3.0

The timeout value in seconds for file/directory (regular) attributes (such as file size, UID, and GID, which are normally stored inside the inode) cache. This value is used to determine whether to use the cached attribute information (only if within the specified timeout window) or fetch attribute information again. The default is 3.0 seconds, which specifies that cached attribute information must be considered stale and refreshed after 3.0 seconds. You can assign fractions of a second as well (for example, `fuse.attr.timeout=2.8`).

Set the value for this parameter to 0 to compare POSIX (pjd) compliance with the ext3/4 file system. A value of 0 disables caching. For better performance, avoid disabling caching.

`fuse.auto.inval.data`

Default Value: 1

Specifies whether (1) or not (0) to automatically invalidate the kernel FUSE cache for any data change that causes mtime change, on the files. If set to 1, when the file is read, the correct file data is returned. If set to 0, the kernel cache of the data, which might not have the most current change, is returned.

`fuse.auto.unmount`

Default Value: 1

Specifies whether to automatically unmount the file system when the process is terminated. Value can be one of:

- 0 - disable
- 1 - enable

`fuse.big.writes`

Default Value: 1

Specifies whether to enable writes larger than 4KB. Value can be one of:

- 0 - disable
- 1 - enable

Sets the size of the data/buffer that can be transferred from the kernel to the FUSE library, per request. If enabled, FUSE allows writes of 128KB from the kernel. If disabled, FUSE allows writes of 4KB from the kernel.

`fuse.client.lib.path`*Default Value:* /tmp

Specifies the path to store the client libraries.

NOTE: To install and use FUSE-based POSIX client and NFS v4 on the same node, ensure that the path for both the client library for the FUSE-based POSIX client, and NFS v4 is not /tmp, which is the default. Specify a different location for the client libraries. For example, /tmp/fuseLib.

`fuse.cluster.conf.location`*Default Value:* /opt/mapr/conf/
mapr-clusters.conf

The path to the configuration file to use.

`fuse.congestion.threshold`*Default Value:* 10

Specifies the kernel's congestion threshold.

`fuse.disable.shardcache`*Default Value:* 0 (false)

Specifies whether to disable shard cache, which is a cache of lookups. Value can be:

- 0 - false
- 1 - true

If true, more number of lookup calls are used. The FUSE client uses the shard cache to ensure that requests for data related to the same file are served by the same library. This is done using hash to improve performance. In very rare circumstances, it might make sense to disable this cache in conjunction with HPE Data Fabric support.

`fuse.disable.writeback`*Default Value:* 0

Specifies whether (1) or not (0) to disable the writeback cache. This parameter is applicable only in kernel versions ≥ 3.15 . By default, in kernel versions ≥ 3.15 , writeback is enabled. To disable writeback cache, set the value for this parameter to 1. If enabled, the writes are buffered in the kernel. However, when multiple FUSE clients work on the same file, writes to a file by one FUSE client might never be seen by other FUSE clients performing a read because the kernel does not update the attributes of the file unless the file is modified locally. You can disable the writeback cache to allow the kernel to perform a write through.

`fuse.enforce.core.pattern`*Default Value:* false

Specifies whether (true) or not (false) to write to /proc/sys/kernel/core_pattern file when the FUSE-based POSIX starts. The default value is false. If true, the core_pattern file contains an /opt/cores/%e.core.%p.%h entry and if false, the file is not touched.

`fuse.entry.timeout`*Default Value:* 3

The timeout value in seconds for the name lookup cache. Use this parameter to determine whether to use the cached entry for the name lookup (if within the specified timeout window) or lookup the name again. The default is 3 seconds, which specifies that cached name lookup information must be considered stale and refreshed after 3 seconds. For this option, it is possible

to give fractions of a second as well (for example, `fuse.entry.timeout=2.8`).

Set the value for this parameter to 0 to compare POSIX (pjd) compliance with the ext3/4 file system. Avoid retaining this value as 0 as it disables the cache, and impacts performance.

`fuse.evently.spread.data`

Default Value: 0

Specifies whether (1) or not (0) to evenly spread writes across the nodes on the cluster. If set to 0, writes are always sent to the local primary node, from where data is replicated on all the other nodes. If set to 1, writes are distributed across different nodes. Set the value to 1 in case of reduced performance resulting from a large number of writes on the local primary node.

`fuse.export`

Default Value: `/mapr`

Denotes the fully-qualified cluster path to the volume or directory under the mount point.

When you do not specify a value, all clusters found in `mapr-clusters.conf` are mounted under the entity specified by the `fuse.mount.point` property (`/mapr` by default). If `mapr-clusters.conf` contains two clusters A and B, there are directories pointing to the root directories of those clusters, for example `/mapr/A` and `/mapr/B`.

When you specify a value, it overrides the default behavior, and causes exactly one path from one cluster to be exposed at the entity specified by the `fuse.mount.point` property. You can either fully expose a single cluster, or expose only a subset of a single cluster.

If you set `fuse.export` to the name of a cluster, enclosed within `/`, then that cluster is mounted at `/mapr`. For example if `fuse.export=/A/`, then the path `/mapr` shows the root directory of cluster A.

If you set `fuse.export` to a path within a cluster, then `/mapr` points to that path. For example, if `fuse.export=/A/var/`, then `/mapr` displays the directory contents of `/var` from the HPE Data Fabric cluster A.

NOTE: If the value is not a valid path to the name of a volume or directory, the FUSE service does not start. The value *cannot* be the path to a file.

`fuse.fast.local.directio`

Default Value: 0

Specifies whether to optimize (1) or disable (0) FUSE client for local direct IO. Value can be one of:

- 0 - disable
- 1 - optimize

`fuse.flush.inline`

Default Value: 0

Specifies whether (1) or not (0) to flush all writes inline. Value can be one of:

- 0 - disable inline flushing
- 1 - flush all writes inline

If disabled, for all open files, by default, the buffer is flushed automatically every 3 seconds or when it reaches 64KB. If enabled, writes are sent to server directly.

`fuse.fsname`

Default Value: FUSE mount point

Specifies the file system source, which is the first field in the `/etc/mtab` file. The default value is the FUSE mount point that is denoted by the parameter `fuse.mount.point`.

`fuse.hb.interval`

Default Value: 5

Specifies the heartbeat interval (in seconds) for the FUSE-based POSIX client.

`fuse.log.debug_level`

Default Value: error

The FUSE-based POSIX client log level. The value can be one of:

- fatal
- error
- warn
- info
- debug

`fuse.log.path`

Default Value: `/opt/mapr/logs`

Specifies the path to store the log files.

`fuse.max.background`

Default Value: 64

Specifies the maximum number of asynchronous requests that can be submitted. IO requests beyond the maximum limit are blocked.

`fuse.max.cache.pages`

Default Value: 1048576 (1 Million pages)

Specifies the maximum number of pages (each page is 8KB) in the page cache that each HPE Data Fabric Client library in FUSE process can use when working with a large number of open files. This setting limits the amount of memory consumed by FUSE.

`fuse.max.read`

Default Value: 131072

Specifies the maximum size (in bytes) of read requests.

`fuse.max.readahead`

Default Value: 131072

Specifies the maximum number of bytes to read ahead.

`fuse.max.write`

Default Value: 131072

Specifies the maximum number of bytes that is allowed in a single write request.

`fuse.mount.point`

Default Value: `/mapr`

This parameter is mandatory. Specifies the mount point where the HPE Data Fabric file system must

be mounted. Ensure that the specified mount point is empty before starting the service. Once mounted, the POSIX client has access to all the clusters specified in `/opt/mapr/conf/mapr-clusters.conf` file. The value should not be `/mapr` if you wish to mask HPE Data Fabric branding.

NOTE: If NFS server is also running on this node, ensure that the FUSE mount point is different from the NFS server mount point.

`fuse.mount.setuid`

Default Value: 0

By default, FUSE mounts with the `nosuid` option. This prevents users other than `root` from running executable files with the SUID bit set, on FUSE. Enable this parameter (set to 1), to allow users other than `root` to run executable files with the SUID bit enabled, on the HPE Data Fabric Fuse File System.

This parameter works in conjunction with the `allowreadforexecute` parameter in [volume create](#) on page 2929 and [volume modify](#) on page 3018 commands.

The following table describes how both parameters work together to permit running SUID binaries:

Table

<code>fuse.mount.setuid</code>	<code>allowreadforexecute</code>	Result
Disabled	Does not matter	SUID binaries cannot be executed by users other than <i>root</i> .
Enabled	Disabled	Users other than <i>root</i> can run the SUID binaries only when the binary has both read and execute permissions .
Enabled	Enabled	Users other than <i>root</i> can execute the SUID binaries either when the binary has both read and execute permissions OR execute permission alone .

`fuse.negative.timeout`

Default Value: 3

Applicable for the Container, Basic, and Platinum POSIX clients.

Indicates the duration in seconds to cache negative lookup results.

Negative lookup results that are returned when a file does not exist (lookup returned ENOENT), are cached for the specified number of seconds. The lookup is performed again, only after this period elapses. The file is deemed to be non-existent till this period elapses.

The default value of 3 indicates that negative lookup results are cached for 3 seconds.

Set this value to 0 to disable the negative lookup cache.

When patching or upgrading the client from an older release, this parameter is automatically applied. However, new parameters are not automatically written to `fuse.conf`. Make sure to copy this parameter from `fuse.conf.new` to `fuse.conf`, only if you want to change the default value, or disable this cache.

`fuse.nonempty`

Default Value: 0

Specifies whether FUSE can be mounted on a non-empty mount point (1) or on an empty mount point (0). Value can be:

- 0 - indicates that mount point should be empty
- 1 - indicates that mount point need not be empty

`fuse.num.libs`

Default Value:

- Container - 1
- Basic - 1
- Platinum - 5

Specifies the number of client libraries to run with. For:

- Container client, value must be 1.
- Basic client, value must be 1.
- Platinum client, default value is 5 and can be set to a value greater than 5.

More than one library allows for more than 1GB/sec throughput on remote operations as each additional library increases the throughput by sharding operations across libraries (for parallelism).

NOTE: Each additional library will consume additional memory and CPU.

`fuse.num.threads`

Default Value: 64

Specifies the number of FUSE threads in userspace per mount point. A higher number allows parallel processing of multiple operations. Recommended value is only up to 64.

`fuse.ra.sessions`

Default Value:

- Container - 1
- Basic - 1

- Platinum - 5

Specifies the number of parallel read ahead sessions per library. Each open file acts as one read ahead session. For example, for the default value of 5, up to 5 files can have read ahead sessions per library. If value is set to 0, readahead is disabled.

NOTE: A greater value allows larger number of parallel read ahead sessions, which is useful if more number of files need to be opened simultaneously. However, each additional read ahead session consumes additional memory (512K per read ahead session) and threads.

`fuse.readdirplus`

Default Value: 1

Enables (1) or disables (0) readdirplus functionality for high latency networks. The readdirplus attribute returns the file handle and attribute information such as the name and the file ID, along with the directory entries, unlike the readdir attribute that requires the client to query the server separately for each directory entry. For the best performance, do not disable this parameter.

`fuse.sync.read`

Default Value: 0

Specifies whether to enable or disable synchronized reads. Value can be:

- 0 - disable
- 1 - enable

`fuse.ticketfile.location`

Default Value: /opt/mapr/conf/maprfuseticket

Specifies the ticket to use to start the service in secure mode. Generate the required ticket and place it in /opt/mapr/conf/<maprfuseticket>.

NOTE: To support impersonation, provide the mapr user ticket file location or the user's servicewithimpersonation ticket file location. You can use the mapr user ticket on the server node, and service with impersonation ticket on client node. The FUSE service must be started by the root user if servicewithimpersonation ticket is specified. In case of non-impersonated ticket, the ticket credentials becomes the identity for all the requests, no matter which user is accessing the fuse mount point.

See also: [Setting up a Ticket for the POSIX Client](#).

`fuse.track.memory`

Default Value: false

Specifies whether to enable (true) or disable (false) memory tracking for FUSE.

`fuse.use.compressed.inode.format`

Default Value: 0

Specifies whether or not to use compressed inode format. When enabled, a 16-bit unique identifier is used to avoid inode cache collisions when multiple clients are modifying (creating, deleting, and similar operations) the same directories/files. The value can be one of:

- 0 — (default) do not use compressed inode format
- 1 — use compressed inode format including unique identifier

NOTE: Even when set to 1, EBUSY errors are returned if client accesses more than 32k volumes at the same time.

Enabling this flag may not completely avoid inode cache collisions when too many modifications such as creation, and deletion are performed on the same directories or files. Give the kernel sufficient time to purge inode cache entries between modifications.

`fuse.xattr.enable`

Default Value: 0 (false)

Specifies whether (true) or not (false) to enable extended attributes through the FUSE client. Value can be one of:

- 0 - false
- 1 - true

The default value is 0 (false). This is disabled by default because if enabled, during operations, the kernel might make a lot of extended attribute calls for security checks resulting in performance degradation even when there are no extended attributes on the inode. When disabled, extended attributes can still be added using the `hadoop fs` command; however, this must be enabled to perform any operations on extended attributes using the FUSE-based POSIX client.

NOTE: Of the five types of extended attribute namespaces in Linux, system, trusted, user, raw, and security, only user namespace is supported. For all other namespaces, EINVAL is returned.

You must start/restart the FUSE-based POSIX client for the changes to take effect. See [Starting and Stopping the POSIX Client](#) for more information.

Configuration Backup When Installing/Upgrading POSIX Clients

When you install a patch, the `/opt/mapr/conf/fuse.conf` file contains the new settings. You can copy the new parameters (with default values) to your existing `fuse.conf` file and restart FUSE for the settings to take effect.

When you upgrade from a prior release, on all supported OS other than Ubuntu, the old `fuse.conf` file is backed up as `fuse.conf.backup`, before being overwritten with the new settings. This backup is available in the `/opt/mapr/conf` directory.

On Ubuntu, the upgrade process does not create a backup copy of the file. You need to manually backup the `fuse.conf` file before upgrading, as this file is overwritten with the new settings after upgrading.

To continue using FUSE with your custom settings, and take advantage of the new settings, manually copy your custom settings in the `fuse.conf.backup` file to the `fuse.conf` file, set custom values for the new parameters in the `fuse.conf` file where necessary, and restart FUSE for the settings to take effect.

To restart FUSE, use one of the following commands depending on the POSIX client of your choice:

- For POSIX container: `service mapr-posix-client-container restart`
- For POSIX basic: `service mapr-posix-client-basic restart`
- For POSIX platinum: `service mapr-posix-client-platinum restart`

Optimizing FUSE performance when running the Flexible I/O tester (fio tool)

Performance Tips

- With Linux kernels prior to version 4.8, size extending writes are serialized by the kernel, and result in degraded write performance. For optimized write performance, ensure that the Linux kernel in use, is at least version 4.8.
- With kernel 4.8 and above, fio performance improves when using larger block sizes and larger number of jobs (numjobs). Keep numjobs constant and use larger block sizes (>128k) for enhanced performance.

For example, for optimised performance, the fio command could be as follows:

```
fio --ioengine=libaio --direct=1 --gtod_reduce=1 --name=perftest --filename=
perfile
      --bs=16m --iodepth=64 --size=4G --rw=write --numjobs=4
```

Configuring Timeout for Inactive Connections

In cases where the file client connects infrequently to a remote CLDB node that is firewalled, TCP segments on the connection are silently dropped by the firewall due to the long idle time. However, the client keeps waiting for the response till RPC times out. To mitigate this scenario, you can now configure the timeout for inactive connections. Use the `fs.mapr.binding.inactive.threshold` parameter in the `core-site.xml` file to set this threshold in seconds. For example:

```
<property>
<name>fs.mapr.binding.inactive.threshold</name>
<value>600</value>
</property>
```

In this example, when the client tries to send data to the CLDB after a certain idle time, the system checks if the specified time (here 600 seconds, that is 10 minutes) is crossed after the previous request was sent. If so, the system tears down the existing TCP connection and creates a new TCP connection for the file client and CLBD to use for communication.

Tuning the Cache for FUSE-Based POSIX Clients

Describes performance tuning measures for FUSE clients.

The FUSE kernel and the FUSE userspace process caches both data and metadata. When an application performs a read of a file using the FUSE-based POSIX client, data is generally returned from the local FUSE kernel cache if that portion of the file resides in cache from a previous read or write operation. However, if the file has been modified on the HPE Data Fabric cluster by a different client, the data in the local kernel cache may be stale. The following illustration shows the layers of cache — FUSE kernel cache (referred to as kCache), the FUSE userspace cache (referred to as uCache), HPE Data Fabric file system cache (referred to as mfsCache) — and the following sections describe how these affect reads and writes and how the FUSE attributes can be used to tune the caching behavior.

Inode Attribute Cache

Inode attributes are cached in the FUSE kernel cache (kCache) and in the userspace cache (uCache). When the same file is accessed from multiple FUSE clients, writes on the file through one mountpoint may not be seen by other applications performing a read on the file (through a different client). The inode attributes are cached in the kernel because of which another application modifying the file might not see the updates instantly. For example, the inode attributes, to name a few, such as size, or modification timestamp (mtime) of the file, in the kCache and uCache on Node A might be stale if the file is being modified concurrently by an application on Node B.

Tuning the attribute timeout in kCache

The FUSE kernel refreshes inode attributes from the userspace FUSE process once every 3 seconds by default. This can be tuned through the `fuse.attr.timeout` parameter in the `fuse.conf` file. The `fuse.attr.timeout` parameter specifies the interval of time at which to refresh the inode attributes in kernel and can be used to minimize the amount of time it takes to refresh the cache. Even if `fuse.attr.timeout` is set to 0, Node A might still not see the latest writes from Node B because there is cached metadata in the userspace FUSE process on Node A; metadata can be served from the uCache and the application might not see current updates for attributes like size. To see the latest changes on a file, see [Tuning the attribute timeout in uCache](#) on page 1886.

Tuning the attribute timeout in uCache

The userspace FUSE process caches both data and metadata and refreshes the inode attributes from the HPE Data Fabric file system once every 3 seconds; *this is not tunable*. Even if the `fuse.attr.timeout` is set to 0, because there is cached data and metadata

in the userspace FUSE process (uCache), stale data or metadata can be served from the userspace FUSE process, which only refreshes inode attributes every 3 seconds. However, the userspace FUSE process updates the inode attributes every time a file is opened. To see the latest changes on a file, applications, especially readers on a file, that require to see updates on the file within 3 seconds can close and open the file to refresh the attributes and see instant updates.

Readdir Cache

Directory entries (files within a directory) are not cached in the uCache, but are cached in the kCache. The kCache can be stale on Node A if there are files being created in the directory by an application from the mountpoint on Node B. That is, a user listing directory entries on Node A for a directory (using a command like ls) might not see the files that were just created from Node B.

Tuning the entry timeout in kCache

The `fuse.entry.timeout` parameter specifies the interval of time at which to refresh the readdir (or lookup) cache in the kernel (kCache). The default value is 3 seconds and this can be configured in the `fuse.conf` file.

Data Cache

By default:

- Reads are buffered both in the kCache and the uCache.
- Writes are not buffered in the kCache, but are buffered in the uCache.

An application trying to read a file on Node A might not see the latest updates to the file (written from node B) for the following reasons:

- Reads on Node A might have been served either from the kCache or the uCache of Node A.
See [Tuning the cache for reads](#) on page 1887 for information on invalidating the cache.
- The writes might have been buffered in the uCache of Node B.

See [Tuning the cache for writes](#) on page 1888 for information on disabling buffering at a file level or altogether.

Tuning the cache for reads

Tuning the kCache

The `fuse.auto.inval.dat` a parameter specifies whether or not to automatically invalidate the kCache for any data change, which causes mtime change, on the files. If enabled, any mtime update on the file automatically invalidates the page cache of the file. The mtime is an inode attribute; for information on refreshing the cache for inode attributes, see Inode Attributes.

	Tuning the uCache	Every read cache page is valid for 3 seconds. After 3 seconds, the read cache page is dropped from uCache. <i>This is not tunable.</i>
Tuning the cache for writes	Tuning the kCache	<p>The <code>fuse.writeback.cache</code> parameter specifies whether to buffer writes in the kernel or to perform a write through. If enabled, the writes are buffered in the kernel. If disabled, writes are not buffered in the kernel and are directly sent to the FUSE process.</p> <p>By default, writeback caching is disabled; that is, the kernel sends all writes to the FUSE process directly. If an application does small writes, then the FUSE process might run out of CPU because of the overhead involved in small writes. To mitigate this, the FUSE kernel can be configured to enable caching in the kernel using the <code>fuse.writeback.cache</code> attribute. However, this can be enabled only on kernels running version ≥ 3.15.</p>
	Tuning the uCache	<p>The <code>fuse.flush.inline</code> attribute can be used to disable data buffering in the uCache. By default, the userspace FUSE process caches the writes locally. This parameter specifies whether to cache writes (for up to 3 seconds or 64KB in size) or write directly to server. This can be disabled at both the file and FUSE process levels.</p> <p>If the application does buffering before writing to file system, to avoid redundant buffering, you can disable buffering at the FUSE level by setting the</p>

`fuse.flush.inline`
parameter value to 1
in the `fuse.conf` file.
Caching can be disabled
at a file-level by opening
the file in `O_DIRECT`
mode.

Caching Negative Lookup Results

FUSE issues thousands of lookup calls for the file, even when the initial lookup call has returned `ENOENT`, indicating that the file that does not exist. This behaviour is in contrast to NFS for the HPE Data Fabric, which caches the lookup result for a specified time. For example, when running a `git clone` operation on the *mapr-core* repository, testing indicated that FUSE issued 870k calls, while NFS for the HPE Data Fabric issued 82k calls, for files that are non-existent.

To reduce the number of negative lookups, and optimize performance, the FUSE configuration contains the `fuse.negative.timeout` parameter.

By default, this parameter is set to 3 seconds. Negative lookup results that are returned when a file does not exist (lookup returned `ENOENT`), are cached for 3 seconds. The lookup is performed again, only after this period elapses. The file is deemed to be non-existent till this period elapses.

For more information on this parameter, check the [FUSE configuration](#).

Configuring HPE Data Fabric FUSE-based POSIX Client for Tenant Environment

Explains the parameters to set to enable tenant user access to tenant shares from the FUSE-based POSIX client.

To enable tenant users to access the tenant share from the FUSE-based POSIX client, set the following configuration parameters in the `fuse.conf` file on the tenant host:

<code>fuse.mount.point</code>	Specifies the local mount path to where the cluster filesystem is going to mount. To mask the HPE Data Fabric branding from the tenant user, do not specify <code>/mapr</code> as the value for this parameter.
<code>fuse.export</code>	Specifies the path to the tenant volume mount path or directory under the tenant volume mount point. This is disabled by default, allowing users to access all the clusters specified in the <code>/opt/mapr/conf/mapr-clusters.conf</code> file. This must be set to enable the user on the tenant host to directly access only the specified volume or directory.
<code>fuse.ticketfile.location</code>	Specifies the path to the tenant ticket file to start the service in secure mode.

For more information on all other available and supported parameters, see [Configuring the HPE Data Fabric FUSE-based POSIX Client](#).

Sample Data Fabric FUSE-Based POSIX Client Configuration File

```
#Set path to the mount point
fuse.mount.point=/mapr

#Set path where logs shall be stored
fuse.log.path=/opt/mapr/logs

#Set path where client libraries shall be stored
fuse.client.lib.path=/tmp
```

```

#Allow all users to access the filesystem
fuse.allow.other=1

#Enable larger than 4kB writes
fuse.big.writes=1

#Enable NUMA affinity
fuse.affinity=0

#Auto unmount on process termination
fuse.auto.unmount=1

#Set number of libMapRClient libraries to run with
#fuse.num.libs=DEFAULT_NUM_LIBS

#Set number of readahead sessions
#fuse.ra.sessions=1

#Enable/Disable memory tracking for fuse
fuse.track.memory=false

#Set number of FUSE threads
#fuse.num.threads=64

#Enable async direct io
fuse.asyncdirect.io=1

#Set the maximum size of read requests
#fuse.max.read=128

#Set the maximum bytes to readahead
#fuse.max.readahead=128k

#Set the maximum size in a single write request
#fuse.max.write=128

#Enable sync reads
#fuse.sync.read=0

#Set number of maximum background requests
fuse.max.background=64

#Set kernel's congestion threshold
#fuse.congestion.threshold=10

#Flush all writes inline
#fuse.flush.inline=0

#Optimize for local direct writes
#fuse.fast.local.directio=0

#Optimize by evenly distribute data across cluster
#fuse.evenly.spread.data=0

#Disable shard cache
#fuse.disable.shardcache=0

#Sets the filesystem source (first field in /etc/mtab).
#The default is the mount program name.
#fuse.fsname=NAME

#Set fuse ticket file
fuse.ticketfile.location=/opt/mapr/conf/maprfuseticket

```

```

#fuse nonempty option to enable mounting at nonempty mount point
#fuse.nonempty=0

#by default, we support user namespace xattr.
#setting below option to 1 will enable the user xattr.
#fuse.xattr.enable=1

#Attribute timeout for inodes
#fuse.attr.timeout=3.0

#Entry timeout for inodes
#fuse.entry.timeout=3.0

#Hearbeat interval for FUSE in seconds
#fuse.hb.interval=5

#fuse sub exports
#fuse.export=/clus.default/vol1

#fuse core pattern
#fuse.enforce.core.pattern=true

#Readonly or readwrite, values are ro,rw
#fuse.access.type=rw

#Auto invalidation of data on mtime change
fuse.auto.inval.data=1

#Disable writeback cache
#If multiple fuse servers are operating on the same file then enabling
#this option will break consistency among different fuse servers i.e.
#writes to file1 on server1 will not be seen by an application reading
#file1 on server2 forever.
fuse.disable.writeback=1

#Set cluster configuration file
#fuse.cluster.conf.location=/opt/mapr/conf/mapr-clusters.conf

#Sets client debug level, values are fatal, error, warn, info, debug
fuse.log.debug_level = error;

#Inode compressed format
fuse.use.compressed.inode.format=0

```

Configuring MAPR_SUBNETS for FUSE-based POSIX Client

Describes how to configure MAPR_SUBNETS and MAPR_SOURCE_HONOUR_SUBNETS environment variables to control client-server storage traffic, such that the client-server communication is restricted to the specified subnet only.

Export the following environment variables on the FUSE-based POSIX client node using the FUSE init script:

Variable	Purpose
MAPR_SUBNETS	Specifies the subnet(s) the client should use, comma separated (e.g., "196.171.4.0/24,172.23.46.0/24")
MAPR_SOURCE_HONOUR_SUBNETS	Set to <code>true</code> to enable client-side subnet enforcement. The default value is <code>false</code> which implies that the kernel selects interface for communication regardless of the subnets specified in the MAPR_SUBNETS environment variable.

Follow the steps given below to control FUSE-based POSIX client–server communication:

1. Add the export statements to the `do_start()` function in the `/opt/mapr/initscripts/mapr-fuse` initscript:

```
export MAPR_SUBNETS="192.168.4.0/24"
export MAPR_SOURCE_HONOUR_SUBNETS="true"
```

2. Save and close the `mapr-fuse` file.
3. Restart the FUSE-based POSIX client.

REMEMBER:

- Any node in the cluster should be routable from every subnet listed in `MAPR_SUBNETS`. Verify routing on all nodes before enabling.
- When an interface listed in `MAPR_SUBNETS` goes down on a FUSE-based POSIX client, ongoing I/O may stall for several minutes before failing over to another interface. The delay occurs because existing TCP connections continue retrying until kernel timeouts expire. Users requiring faster failover should tune TCP retry settings appropriately.

Managing the FUSE-Based POSIX Client

Describes how to use the FUSE-based POSIX client.

Ports Needed for POSIX Clients and File System to Communicate With Each Other

POSIX clients communicate with the CLDB and server components of the HPE Data Fabric file system. You need to open the relevant ports for **TCP** connectivity from POSIX clients to the HPE Data Fabric file-system cluster nodes. Open the CLDB, file-system server, and file-system server instances ports.

- CLDB - Ports 7222 and 7223.
- File-System Server - 5660, 5692, 5724, 5756, and 6660.

For better performance, you can open additional CLDB ports. See [Ports Used by HPE Data Fabric Software](#) on page 3469 for more information.

When using Multi-MFS instances, open the relevant ports for these instances to work. For example, instance 0 will use four ports from 5660, 5692 (5660+32), 5724 (5660+64), and 5756 (5660+96), instance 1 will use four ports from 5661, 5693, 5725, 5757, and so on for every additional instance. See [Working with Multiple Instances of the File System](#) on page 1356 for more information.

Setting up a Ticket for the POSIX Client

The POSIX client can be accessed using user and service tickets. The service tickets have long lifetimes, by default, for ease of administration. This is useful for running application processes that should not be bounded by the CLDB duration (`cldb.security.user.ticket.duration.seconds`) and renewal (`cldb.security.user.ticket.max.duration.seconds`) properties, which limit the lifetime of user tickets. If you plan to use a user ticket, ensure that the user has read permissions on the ticket file.

Regardless of the ticket type, after generating the ticket, set the `fuse.ticketfile.location` parameter value in the `fuse.conf` file to point to the ticket file to use.

For more information, see:

- [Generating a HPE Data Fabric User Ticket](#) on page 2103
- [Generating a Service Ticket](#) on page 2104

NOTE: If the UID/GID in the ticket (without impersonation capability) is different from the UID/GID of the logged-in user, all operations are performed using the UID/GID of the ticket and not that of the logged-in user.

Starting and Stopping the POSIX Client

To ensure that the service can be started and stopped and to run the help option, set the shared `LD_LIBRARY_PATH` environment variable. Update the shared library environment variable to include the paths to the following:

- Full path to the directory containing `libjvm.so` file
- `$MAPR_HOME/lib` (that is, `/opt/mapr/lib` directory)

For example:

```
export LD_LIBRARY_PATH=/usr/lib/jvm/
java-1.7.0-openjdk-1.7.0.79.x86_64/jre/lib/amd64/server/:/opt/mapr/lib
```

To allow a non-root user to start this service, as administrator or root user, run the following command:

```
chmod u+s /opt/mapr/bin/fusermount
```

Verify that permissions have been set for the non-root user to start the service. For example:

```
ls -l /opt/mapr/bin/fusermount
```

Your output should look similar to the following:

```
-rwsr-xr-x 1 root root 39704 Feb 16 19:41 /opt/mapr/bin/fusermount
```

Ensure that the non-root user has full permissions on the mount point and log files.

To manually start or stop the service:

```
service mapr-posix-client-* [start|stop|status]
```

When you run the command, replace `*` with `basic` or `platinum`, which corresponds with the package that is installed on the system.

NOTE: The POSIX client service cannot be stopped or restarted if any other process is accessing the mount point. With `systemd` (on CentOS/RH 7.x and SLES 12), the service will enter failed state (if you tried to stop) or activating state (if you tried to restart) and you must manually kill the client processes.

Running the POSIX Client in Secure Mode

The POSIX client reads the `mapr-clusters.conf` file to determine whether the process must start in secure or non-secure mode. If security is configured, the `servicewithimpersonation` ticket file must be present in the default `/tmp` directory. If the ticket file is not in the default `/tmp` directory, specify the location of the ticket file using the `fuse.ticketfile.location` configuration parameter in the `fuse.conf` file

TIP: See also: [Enabling Impersonation for the HPE Data Fabric Superuser](#) on page 2217 and [Enabling Impersonation for any User](#) on page 2218.

If the ticket expires after a connection has been established between the POSIX client and the cluster, the connection can stay alive for up to an hour. No new connections will be allowed. If the access to the ticket was denied, restart POSIX client to refresh the ticket.

Mounting the File System

To mount the HPE Data Fabric file system at the mount point specified in the `/opt/mapr/conf/fuse.conf` file, create the mount point specified in the `fuse.conf` file and start the service. For example:

```
mkdir /mapr
service mapr-posix-client-* start
```

NOTE: If security software blocks the FUSE subsystem or kernel, the mounting process can be inhibited, or access to the FUSE mount using available commands can hang. Examples of such security software include:

- CrowdStrike Falcon Sensor Service
- Vormetric Data Security Manager
- Tripwire file-integrity monitoring solutions
- Symantec Agent for Linux IDS daemon

Contact your HPE customer support representative if you experience related issues.

NOTE: When you run the command, replace `*` with `basic` or `platinum`, which corresponds with the package that is installed on the system.

ATTENTION: Remember the following points when using a FUSE mounted file system:

- When trying to open a FIFO on a FUSE mounted file system, permissions to perform the operation are not checked.
- Any user can set time using `touch -t` for any file on a FUSE mounted file system.

See also: [Enabling Soft Mount and Setting the Timeout](#) on page 410

Monitoring the POSIX Client

To determine whether the POSIX client is running, run the following command:

```
service mapr-posix-client-* status
```

NOTE: When you run the command, replace `*` with `basic` or `platinum`, which corresponds with the package that is installed on the system.

Adding and Removing Users

Before you add and/or remove users using the POSIX client, make a note of the following:

- Invalid UID/GID cannot perform operations on the system.
- When you add or remove users, it may take up to 30 minutes for the changes to take effect.

By default, the UID cache will expire in 30 minutes. To disable UID cache, set the value (in seconds) for `fs.mapr.uid.cache.timeout.seconds` parameter in the `core-site.xml` file. You can set the value to:

- 0 to fetch the GID information from the idstore directly
- >0 to specify the amount of time to keep the UID information in cache

For example, your `core-site.xml` entry would look similar to the following for:

- Disabling cache:

```
<property>
  <name>fs.mapr.uid.cache.timeout.seconds</name>
  <value>0</value>
  <description>disable UID cache</description>
</property>
```

- Setting 3 minutes as the amount of time to keep the UID information in cache:

```
<property>
  <name>fs.mapr.uid.cache.timeout.seconds</name>
  <value>180</value>
  <description>UID cached for 3 minutes</description>
</property>
```

Registering POSIX Client with Additional Clusters

To register the POSIX client with additional clusters, you must add entries directly to the `/opt/mapr/conf/mapr-clusters.conf` file. The clusters will be visible after few minutes.

NOTE: Each client supports up to 16 clusters.

Configuring the FUSE Read Chunk Size

The POSIX FUSE platinum client can break large reads into multiple pieces to be handled in parallel, if you set the FUSE read chunk size of a file. This process is called sharding.

By default, the FUSE read chunk size is set to 2 MB. To change the chunk size used by the FUSE platinum client for parallel reads, set the value (in bytes) for the `fs.mapr.fuseshard.chunksize` configuration field in the `core-site.xml` file. To set the chunksize to 5 MB (5242880 bytes), use:

```
<property>
  <name>fs.mapr.fuseshard.chunksize</name>
  <value>5242880</value>
  <description>setting chunk size</description>
</property>
```

For example, if the FUSE read chunk size is set to 1 MB, and the FUSE platinum client is configured with 5 libraries, then the platinum client reads 5 MB in parallel.

Unmounting the FUSE Mount

To unmount the mountpoint and kill the FUSE process, run the following command:

```
service mapr-posix-client-* stop
```

NOTE: When you run the command, replace `*` with `basic` or `platinum`, which corresponds with the package that is installed on the system.

Troubleshooting the FUSE-Based POSIX Client

Explains how to enable and collect the stack trace to troubleshoot POSIX client issues.

This section contains information for troubleshooting the FUSE-based POSIX client.

Enabling Traces

To enable traces at system startup, set the property `fs.mapr.trace` in the `core-site.xml` file. For example:

```
<property>
  <name>fs.mapr.trace</name>
  <value>DEBUG | INFO | WARN | ERROR | CRITICAL | OFF</value>
  <description> </description>
</property>
```

Collecting the Stack Trace

If the mountpoint is not responding or if the file system operations are taking too much time, collect the stack trace of all the threads to debug. To collect the stack trace of all threads, run the following command:

```
gstack <fuse-process-id> > ./gstack.log
```

If the file system commands fail, repeat the file system command with `strace` and collect the log file:

```
strace <file system command> > ./strace.log
```

Issue: FUSE POSIX client does not honor the MAPR_SUBNETS environment variable

The FUSE POSIX client may not honor the `MAPR_SUBNETS` environment variable on client nodes. When you set `MAPR_SUBNETS` on a client node to restrict FUSE traffic to a specific network interface (for example, `192.168.4.0/24`), the POSIX client may continue to use **both** NICs to communicate with data nodes, instead of restricting to the specified subnet only.

Cause

The `MAPR_SOURCE_HONOUR_SUBNETS` flag controls **source-side filtering** of client connections based on the subnets configured in `MAPR_SUBNETS`. When this flag is set to `true` on the client, the FUSE/POSIX client attempts to use only those local interfaces whose IPs fall within the CIDR ranges listed in `MAPR_SUBNETS`. If `MAPR_SUBNETS` is incomplete or incorrect, or if `MAPR_SOURCE_HONOUR_SUBNETS` is not set as expected, source IP selection may not match the intended storage network design.

Resolution:

A fix has been implemented at the **RPC layer** to enforce source IP selection on the client side based on `MAPR_SUBNETS`. The logic works as follows:

- When `MAPR_SUBNETS` is not set (default), it uses `INADDR_ANY` (the kernel selects the interface).
- When one or more subnets are specified in `MAPR_SUBNETS`, it uses the source IP of the client node matching that subnet mask.

**NOTE:**

- Every subnet listed in MAPR_SUBNETS must be routable from all cluster nodes. If any data node lacks a route to the client's source subnet, write operations may hang or fail. Verify routing on all nodes before enabling.
- When an interface listed in MAPR_SUBNETS goes down on a FUSE client, ongoing I/O may stall for several minutes before failing over to another interface. The delay occurs because existing TCP connections continue retrying until kernel timeouts expire, which is controlled largely by net.ipv4.tcp_retries2, and additional time is required for RPC reconnect and FUSE cidcache refresh. Users requiring faster failover should tune TCP retry settings appropriately.

Configuration Required

To enable the fix, export these environment variables on the client node using the FUSE init script:

Variable	Purpose
MAPR_SUBNETS	Specifies the subnet(s) the client should use, comma separated (for example, "196.171.4.0/24,172.23.46.0/24")
MAPR_SOURCE_HONOUR_SUBNETS	Must be enabled (set to true) to activate client-side subnet enforcement. By default it is disabled which means the kernel selects the interface for communication regardless of MAPR_SUBNETS.

Example:

```
# vim /opt/mapr/initscripts/mapr-fuse
# Function to mount the filesystem, if not already mounted.
do_start()
{
    export MAPR_SUBNETS="192.168.4.0/24"
    export MAPR_SOURCE_HONOUR_SUBNETS="true"
```

Managing the MAST Gateway**About this task**

You can start, stop, and restart the MAST Gateway using the Control System and the CLI. You can also configure how frequently Data Fabric runs the load balancer to balance the load on the MAST Gateway.

Configuring the MAST Gateway Service**About this task**

After installing MAST Gateway service, perform the following steps on the node if file system is not installed on the node. If file system is (also) installed on the node, start at step 4:

Procedure

1. Run [configure.sh](#) on page 3186 utility.

For example:

```
/opt/mapr/server/configure.sh -C <CLDB nodes> -Z <Zookeeper nodes> -N
<ClusterName>
```

2. Start Warden if it is already not running.

```
service mapr-warden start
```

3. Run `jps` or `/etc/init.d/mapr-mastgateway status` to check whether MAST Gateway is running on the node.

4. Open the `/opt/mapr/conf/mastgateway.conf` file and set values for the following parameters:

Parameter	Default Value	Description
<code>mastgateway.port</code>	8660	The port on which the MAST Gateway process runs. Default value is 8660.
<code>mastgateway.worker.numthreads</code>	16	The number of threads to execute tiered data operations such as read and modify part of the offloaded data. The default value is 16. You can modify this based on the machine's configuration.
<code>mastgateway.cntr.worker.numthreads</code>	16	The number of threads to use to execute container-based tiered data operations such as offload and recall of file-level and volume-level data in parallel. The default value is 16. TIP: For faster offload, modify this value based on the machine's configuration.
<code>mastgateway.logfile.size.mb</code>	1024	The maximum size (in MB) of the MAST Gateway log file. When the size limit is reached, the logs get rolled over.
<code>mastgateway.readsvccops.nthreads</code>	0	The number of threads in the exclusive threadpool that serves the read operations for MAST gateway. 0 indicates that there is no separate threadpool for the MAST gateway to cater to read operations on tiered volumes. Set the value to a non-zero positive integer representing the number of threads to serve the read operations for the MAST gateway. For example, if you want to assign 16 threads in the threadpool that serves the MAST gateway exclusively for read operations on volumes, you can set the value of the <code>mastgateway.readsvccops.nthreads</code> parameter to 16.

Parameter	Default Value	Description
mastgateway.debug.nthreads	0	<p>The number of threads in the exclusive threadpool that serves the debug operations on the MAST gateway.</p> <p>0 indicates that there is no separate threadpool to cater to debug commands/operations on MAST gateway.</p> <p>Set the value to a non-zero positive integer representing the number of threads to serve the debug commands/operations on the MAST gateway.</p> <p>For example, if you want 16 threads in the threadpool that serves the debug commands/operations related to the MAST gateway, you can set the value of the mastgateway.debug.nthreads parameter to 16.</p>

NOTE: If you modify the mastgateway.conf file, you must restart the MAST Gateway for the changes to take effect.

- (Optional) Add the following parameters in the /opt/mapr/conf/mastgateway.conf file only if you wish to customize libcurl.

The MAST Gateway uses libcurl to perform tiering-related operations. The following table lists the customizable libcurl options and their default values. If these are not set in the mastgateway.conf file, the default values are used.

NOTE: In the mastgateway.conf file, add only the parameters that you wish to customize.

Parameter	Default Value	Description
mastgateway.curl.timeout	300000	Timeout for the entire request.
mastgateway.curl.connecttimeout	60000	Timeout for the connection phase.
mastgateway.curl.nosignal	0	Do not install signal handlers.
mastgateway.curl.followlocation	0	Follow HTTP redirects.
mastgateway.curl.maxsendspeed	0	Limit on data upload speed.
mastgateway.curl.maxrecvspeed	0	Limit on data download speed.
mastgateway.curl.maxconnections	5	Maximum number of connections in the connection pool.
mastgateway.curl.dnsservers	null	Preferred DNS servers.
mastgateway.curl.interface	null	Bind connection locally to this.
mastgateway.curl.verifypeer	1	Verify the SSL certificate.

Parameter	Default Value	Description
mastgateway.curl.verifyhost	2	Verify the host name in the SSL certificate.
mastgateway.curl.cainfo	null	CA cert bundle.
mastgateway.curl.issuercert	null	Issuer certificate.
mastgateway.curl.sslcert	null	Client cert.
mastgateway.curl.sslcerttype	null	Client cert type.
mastgateway.curl.sslkey	null	Client key.
mastgateway.curl.sslkeytype	null	Client key type.
mastgateway.curl.sslkeypasswd	null	Client key password.
mastgateway.curl.proxy	null	Proxy to use. Note: Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information.
mastgateway.curl.preproxy	null	Socks proxy to use.
mastgateway.curl.proxyport	0	Proxy port to use. Note: Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information.
mastgateway.curl.proxytype	0	Proxy type. Note: Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information.
mastgateway.curl.httpproxytunnel	0	Tunnel through the HTTP proxy. Note: Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information.
mastgateway.curl.proxyuser	null	Proxy user name. Note: Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information.

Parameter	Default Value	Description
mastgateway.curl.proxypasswd	null	Proxy password. Note: Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information.
mastgateway.curl.proxyauth	1	HTTP proxy authentication methods. Note: Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information.
mastgateway.curl.proxyverifypeer	1	Verify the proxy's SSL certificate.
mastgateway.curl.proxyverifyhost	2	Verify the proxy certificate's name against host.
mastgateway.curl.proxycainfo	null	Path to proxy Certificate Authority (CA) bundle.
mastgateway.curl.proxysslcert	null	SSL proxy client certificate.
mastgateway.curl.proxysslcerttype	null	Type of the proxy client SSL certificate.
mastgateway.curl.proxysslkey	null	Private keyfile for TLS and SSL proxy client cert.
mastgateway.curl.proxysslkeytype	null	Type of proxy private key file.
mastgateway.curl.proxysslkeypasswd	null	Passphrase for proxy private key.

For example, to configure the MAST Gateway for proxy server, your mastgateway.conf file settings for proxy server should look similar to the following:

```

mastgateway.curl.proxy=10.20.30.140

mastgateway.curl.preproxy=null

mastgateway.curl.proxyport=3128

mastgateway.curl.proxytype=0

mastgateway.curl.httpproxytunnel=0

mastgateway.curl.proxyuser=proxyuser

mastgateway.curl.proxypasswd=proxyuserpwd

```

```
mastgateway.curl.proxyauth=1
```

6. Save and close the `/opt/mapr/conf/mastgateway.conf` file.
7. (Optional) Configure memory for the MAST Gateway in the `/opt/mapr/conf/conf.d/warden.mastgateway.conf` file by setting values for the following parameters:

Parameter	Default Value	Description
<code>service.heapsize.min</code>	2048	The minimum amount of node memory (in MB) to allocate.
<code>service.heapsize.max</code>	20480	The maximum amount of node memory (in MB) allocate.
<code>service.heapsize.percent</code>	10	The percentage of node memory to allocate.

By default, 10% of the node memory or 20GB, whichever is lower, is allocated to MAST Gateway. If the MAST Gateway is processing jobs for both warm and cold tiers, memory consumption can increase up to 7GB or more. If you see high memory alarms for small memory consumption also, tune the percentage of memory allocated for MAST Gateway. Ensure that the percentage of memory allocated through `service.heapsize.percent` is available for MAST Gateway.

8. (Optional) Set the value for `fs.mapr.pool.queue.max_size` parameter to 20000 in the `/opt/mapr/conf/dbclient.conf` file.

If compression is enabled on the data in a tiering-enabled volume, tiering jobs can fail and return errors because of the large number of operations sent to the DB (where metadata for offloaded data is stored). To prevent errors, add the `fs.mapr.pool.queue.max_size` parameter to the `/opt/mapr/conf/dbclient.conf` file and set the value for this parameter to a large number, such as 20000. For example, your entry in the `/opt/mapr/conf/dbclient.conf` file should look similar to the following:

```
fs.mapr.pool.queue.max_size = 20000
```

9. Restart the MAST Gateway for the changes to take effect.
See [Starting, Stopping, and Restarting the MAST Gateway](#) on page 1903 for more information.

Configuring Secure Access

About this task

If the Data Fabric cluster is a secure cluster and the MAST Gateway is installed on a cluster node, no additional configuration is needed for the MAST Gateway to access data. On the other hand, if the Data Fabric cluster is a secure cluster and if MAST Gateway is installed on an edge node, to enable the MAST Gateway to communicate with the secure Data Fabric cluster, do the following:

Procedure

1. Copy the `/opt/mapr/conf/maprserverticket`, `/opt/mapr/conf/ssl_keystore`, and `/opt/mapr/conf/ssl_truststore` files on the CLDB node to the `/opt/mapr/conf` directory on the edge node.

2. Run `configure.sh` as shown below:

```
/opt/mapr/server/configure.sh -C <cldb-node-IP-addresses> -Z
<zookeeper-node-IP-addresses> -secure -N <cluster-name>
```

See [configure.sh](#) on page 3186 for more information.

Starting, Stopping, and Restarting the MAST Gateway

About this task

You can start, stop, and restart the MAST Gateway using the Control System and the CLI.

Starting, Stopping, and Restarting the MAST Gateway Using the Control System

About this task

See:

- [Starting the Services on the Cluster Using the Control System](#) on page 1401
- [Stopping a Service on the Cluster Using the Control System](#) on page 1402
- [Restarting the Services on the Cluster Using the Control System](#) on page 1403

Starting, Stopping, and Restarting the MAST Gateway Using the CLI

Procedure

- Run the following command to:
 - Start the MAST Gateway:

```
maprccli node services -nodes <nodename|IP_address> -name
mastgateway -action start
```

- Stop the MAST Gateway:

```
maprccli node services -nodes <nodename|IP_address> -name
mastgateway -action stop
```

- Restart the MAST Gateway:

```
maprccli node services -nodes <nodename|IP_address> -name
mastgateway -action restart
```

Balancing Gateway Load

Explains how CLDB balances MAST Gateway loads.

About this task

CLDB assigns volumes to MAST Gateways so that any tiering-related operation for a volume is performed by the MAST Gateway assigned to the volume. This assignment is sticky and the volume remains assigned to the same gateway across CLDB, MAST Gateway, and cluster restarts. When a MAST Gateway goes down, volumes assigned to the MAST Gateway are not re-assigned immediately. Instead, when a tiering operation needs to be run and the assigned MAST Gateway is down, CLDB assigns a new MAST Gateway to the volume, and the operation is performed using the newly assigned MAST Gateway.

Volumes are assigned to gateways with the lowest load (or lowest number of volumes currently assigned to it) to ensure equal distribution. Whenever a volume is created or removed or whenever a MAST Gateway is added or removed, the load on the gateways require rebalancing. HPE Data Fabric automatically balances the load on the gateways after a certain (configurable) amount of time since the occurrence of the event that necessitates a rebalance. The delay after which HPE Data Fabric tries to rebalance varies based on the type of event that necessitates a rebalance. See [Configuring the Delay After Which Load Balancer runs for Events](#) on page 1904 for more information.

Each volume in the cluster is assigned a weight, which is 1 for all volumes. The load on a gateway is the sum of weights of all the volumes that are assigned to the gateway. Load balancer tries to ensure that the load on a gateway is at least the average weight.

```
avg weight = (sum(weight of all tiered vols) + num active gws - 1) / num
active gws
```

When the balancer needs to pick volumes from a gateway for reassignment, it first picks the volume with max weight and one that currently has no activity (volume level offload, recall, or compaction). To minimize the interruptions in gateway activity, the balancer first considers idle volumes and picks volumes with active tasks after. However, any balancing and/or reassignment is skipped if there is already assignment related flux in the cluster (such as volumes with gateway assignment currently in progress). If this happens, load balancer runs again with a shorter time delay of 10 minutes.

HPE Data Fabric performs load balancing in batches of 5 volumes per run. That is, it assigns 5 volumes to gateways and then after a delay of 10 minutes by default, runs the load balancer again to distribute other volumes (in batches of 5). HPE Data Fabric figures out the next batch of volumes by re-evaluating the current assignment state. When the load on the gateway is balanced, the balancer is disabled and the load balancer is run again only by any of the 4 events.

Configuring Interval Between Load Balancer Runs

Procedure

- HPE Data Fabric assigns 5 volumes to gateways and then after a delay of 10 minutes by default, runs the load balancer again to distribute other volumes (in batches of 5). Run the following command to configure the interval between runs:

```
maprcli config save -values
{"cldb.tier.gw.balance.delay.recheck":"<time-in-seconds>"}
```

Configuring the Delay After Which Load Balancer runs for Events

About this task

HPE Data Fabric runs the load balancer automatically for any of the following events. You can configure the delay after which HPE Data Fabric runs the load balancer.

Create Volume

When you create a tiering-enabled volume, it is assigned the gateway with the lowest load. If gateways are not available for the volume at the time of creation, the volume might stay unassigned. To ensure that the volume has an associated gateway for handling the tiering operations, HPE Data Fabric runs the gateway load balancer after a delay of 2 hours (7200 seconds) by default for this event.

To configure the delay, set the value for `cldb.tier.gw.balance.delay.vol.create`

property (in seconds) using the [config save](#) on page 2394 command. For example:

```
maprcli config save -values
{"cldb.tier.gw.balance.delay.vol.create":"<time-in-seconds>"}
```

Remove Volume

When you remove a volume, the distribution of volumes across gateways can become uneven, and the balancer must be run to redistribute the volumes. For this event, HPE Data Fabric runs the load balancer to redistribute the volumes and rebalance the gateways after a delay of 2 hours (7200 seconds) by default for this event.

To configure the delay, set the value for the `cldb.tier.gw.balance.delay.vol.delete` property (in seconds) using the [config save](#) on page 2394 command. For example:

```
maprcli config save -values
{"cldb.tier.gw.balance.delay.vol.delete":"<time-in-seconds>"}
```

Add Gateway

When you install a new gateway on a cluster, volumes are assigned to the new gateway only if a new volume is created or an existing volume has a pending task, but no active assigned gateway. Volumes that have active gateways are not re-assigned by default. For this event, HPE Data Fabric runs the load balancer to re-distribute the volumes and rebalance the gateway load after a delay of 2 hours (7200 seconds) by default.

To configure the delay, set the value for the `cldb.tier.gw.balance.delay.new.gw` property (in seconds) using the [config save](#) on page 2394 command. For example:

```
maprcli config save -values
{"cldb.tier.gw.balance.delay.new.gw":"<time-in-seconds>"}
```

Remove Gateway

When you remove a gateway or when a gateway goes down, all the volumes assigned to the gateway are not re-assigned by default; only volumes with pending tasks are assigned to new gateways. For this event, HPE Data Fabric runs the load balancer to re-distribute the volumes after 6 hours (21600 seconds) by default.

To configure the delay, set the value for the `cldb.tier.gw.balance.delay.dead.gw` property (in seconds) using the [config save](#) on page 2394 command. For example:

```
maprcli config save -values
{"cldb.tier.gw.balance.delay.dead.gw":"<time-in-seconds>"}
```

Determining the Volumes Assigned to MAST Gateways

Procedure

- Run one of the following commands to determine the volumes that are assigned to MAST Gateways:

- `/opt/mapr/server/mrconfig info mastgateway`

- `/opt/mapr/server/mrconfig info volume mastgateway`

For more information, see [mrconfig info](#) on page 3306.

Enabling Debug Logging for MAST Gateway

About this task

The MAST Gateway service log file contains alarm messages, error codes, and information on the errors. When the `mastgateway.log` file reaches `mastgateway.logfile.size.mb/5`, a roll over happens and the `mastgateway.log` file is renamed as `mastgateway.log.1`; also, a new `mastgateway.log` file is created. When the newly created `mastgateway.log` reaches `mastgateway.logfile.size.mb/5`, a roll over happens again and:

- The `mastgateway.log.1` is renamed as `mastgateway.log.2`
- The `mastgateway.log` is renamed as `mastgateway.log.1`
- A new `mastgateway.log` is created

This process continues and up to 5 files, whose size is `mastgateway.logfile.size.mb/5`, are created before the oldest log file, `mastgateway.log.4`, is deleted.

Procedure

- Run the following command to enable debug logging for MAST Gateway:

```
maprcli trace setlevel -module MASTGateway -level Debug -port 8660
```

Configuring YARN for Control Groups

Control groups (cgroups) are a Linux kernel feature available through the LinuxContainerExecutor program that you can configure to limit and monitor the CPU resources available to YARN container processes on a node.

To enable cgroups, follow the Apache instructions for [Using CGroups with YARN](#), but note that the default directory for `yarn.nodemanager.linux-container-executor.cgroups.hierarchy` (hadoop-yarn) is created automatically in the default place (`/sys/fs/cgroup/cpu,cpuacct/`) by `mapr-warden`, and permissions are set to the `mapr` user.

If you run Spark jobs, note the following consideration. When deployed in `client` mode, Spark driver programs are not controlled by cgroups, but the tasks are. In `cluster` mode, both the driver and tasks are controlled by cgroups. For more information about these modes, see [Deployment Modes](#) on page 5426.

Related tasks

[Restarting Services](#) on page 1402

Describes how to restart a service using either the Control System, the CLI or the REST API.

Configuring NodeManager Restart

About this task

NodeManager restart is enabled by default. Active containers will keep running in the event that the NodeManager shuts down.

When the NodeManager restart is enabled, it stores the container state of active containers in a recovery directory; when the NodeManager restarts, it retrieves the container state from the recovery directory.

If you disable NodeManager restart, active containers are shut down when the NodeManager shuts down and containers need to be reallocated when the NodeManager starts again.

To configure NodeManager restart, enable the NodeManager recovery and also specify a port that can be dedicated to run the NodeManager service.

Procedure

1. Add the following parameters to the `yarn-site.xml` on each NodeManager node:

- a) Set `yarn.nodemanager.recovery.enabled` to `true`.
- b) Set `yarn.nodemanager.address` to include a port that is dedicated to run the NodeManager on this node.
- c) Optionally, set `yarn.nodemanager.recovery.dir` to a different recovery directory for this node.

By default, the recovery directory is set to `$hadoop.tmp.dir/yarn-nm-recovery` which resolves to `tmp/hadoop-mapr/nm-local-dir/yarn-nm-recovery`. See the following example configuration:

```
<property>
  <name>yarn.nodemanager.recovery.enabled</name>
  <value>true</value>
</property>
<property>
  <name>yarn.nodemanager.address</name>
  <value>0.0.0.0:8099</value>
</property>
```

2. Restart the NodeManager Service.

For more information, see [Managing Services](#) on page 1397.

Managing Jobs and Applications

If you have used Hadoop in the past to run MapReduce applications, then running jobs on the HPE Data Fabric platform will be very familiar to you. HPE Data Fabric is a full Hadoop distribution, API-compatible with all versions of Hadoop. HPE Data Fabric provides additional capabilities not present in any other Hadoop distribution.

You can perform the following procedures to manage applications in a HPE Data Fabric cluster:

Job Scheduling

You can use job scheduling to prioritize the YARN applications that run on your MapR cluster.

The MapReduce system supports a minimum of one queue, named `default`. Hence, this parameter's value should always contain the string `default`. Some job schedulers, like the Capacity Scheduler, support multiple queues.

The default job scheduler is the Fair Scheduler, which is designed for a production environment with multiple users or groups that compete for cluster resources.

The MapR Converged Data Platform supports these job schedulers:

- **FIFO queue-based scheduler:** The FIFO queue scheduler runs jobs based on the order in which the jobs were submitted. You can prioritize a job by changing the value of the `mapred.job.priority` property or by calling the `setJobPriority()` method.
- **Fair Scheduler:** This is the default scheduler. The Fair Scheduler allocates a share of cluster capacity to each user over time. The design goal of the Fair Scheduler is to assign resources to jobs so that each job receives an equal share of resources over time. The Fair Scheduler enforces fair sharing within each queue. Running jobs share the queue's resources.
- **Capacity Scheduler:** The Capacity Scheduler enables users or organizations to simulate an individual hadoop cluster with FIFO scheduling for each user or organization. You can define organizations using *queues*.

The following sections provide more information about job scheduling:

Hadoop 3.x Fair Scheduler

The FairScheduler is a pluggable scheduler for Hadoop that allows YARN applications to share resources in a large cluster fairly. Fair scheduling is a method of assigning resources to applications such that all applications get, on average, an equal share of resources over time. Hadoop 3.x is capable of scheduling multiple resource types.

By default, the Fair Scheduler bases scheduling fairness decisions only on memory. It can be configured to schedule resources based on memory, CPU, and disk usage. When only one application is running, that application uses the entire cluster. When other applications are submitted, resources that free up are assigned to the new applications, so that each application eventually gets approximately the same amount of resources. Unlike the default Hadoop scheduler, which forms a queue of applications, this lets short applications finish in reasonable time while not starving long-lived applications. It is also a reasonable way to share a cluster between a number of users. Finally, fair sharing also uses priorities applied as weights to determine the fraction of total resources that each application should get.

For additional information about Hadoop Fair Scheduler, you can also refer to the [open source documentation](#).

Scheduling Queues

The scheduler organizes applications further into *queues*, and shares resources fairly between these queues. By default, all users share a single queue, named `default`. If an application specifically lists a queue in a container resource request, the request is submitted to that queue. You can also assign queues based on the user name included with the request through configuration. Within each queue, a scheduling policy is used to share resources between the running applications. The default is memory-based fair sharing, but FIFO and multi-resource with Dominant Resource Fairness can also be configured.

Queues can be arranged in a hierarchy to divide resources, and they can be configured with weights to share the cluster in specific proportions. The Fair Scheduler uses a concept called a *queue path* to configure a hierarchy of queues. The queue path is the full path of the queue's hierarchy, starting at *root*. The following example has three top-level child-queues a, b, and c and some sub-queues for a and b:

In addition to providing fair sharing, the Fair Scheduler allows assigning guaranteed minimum shares to queues, which is useful for ensuring that certain users, groups or production applications always get sufficient resources. When a queue contains apps, it gets at least its minimum share, but when the queue does not need its full guaranteed share, the excess is split between other running apps. This lets the scheduler guarantee capacity for queues while utilizing resources efficiently when these queues do not contain applications.

Configuring the Fair Scheduler

The Fair Scheduler lets all applications run by default, but you can also limit the number of running applications per user and per queue through the configuration file. This can be useful when a user must submit hundreds of applications at once, or in general to improve performance if running too many applications at once would cause too much intermediate data to be created or too much context-switching. Limiting the applications does not cause any subsequently submitted applications to fail; it only causes them to wait in the scheduler's queue until earlier applications finish.

To customize the Fair Scheduler, set the [configuration properties](#) in `yarn-site.xml` and update the allocation file to list existing queues and their respective weights and capacities. The allocation file is automatically created during HPE Data Fabric installation in the following directory:

```
{$MAPR_HOME}/hadoop/hadoop-2.x/etc/hadoop/fair-scheduler.xml
```

The allocation file is reloaded every 10 seconds to refresh the scheduler with any modified settings that are specified in the file.

Specifying Fair Scheduler Configuration Properties in yarn-site.xml

Lists the properties in the `yarn-site.xml` file for Fair Scheduler.

The [yarn-site.xml](#) file contains the following parameters that determine scheduler-wide options.

yarn.scheduler.fair.allocation.file

Default Value: `fair-scheduler.xml`

Description: Specifies the path to the allocation file. If a relative path is given, the file is searched for on the classpath.

yarn.scheduler.fair.user-as-default-queue

Default Value: `true`

Description: Determines whether to use the username associated with the allocation file as the default queue name, if a queue name is not specified.

yarn.scheduler.fair.preemption

NOTE: If a queue placement policy is given in the allocations file, this property is ignored.

Default Value: false

Description: Indicates whether to use preemption.

NOTE: Do not use preemption when FairScheduler DominantResourceFairness is in use and node labels are present.

yarn.scheduler.fair.sizebasedweight

Default Value: false

Description: Indicates whether to assign shares to individual applications based on their size, rather than providing an equal share to all applications regardless of size. When set to true, applications are weighted by $(\ln 1 + \text{application's total requested memory}) / \ln 2$.

yarn.scheduler.fair.assignmultiple

Default Value: false

Description: Indicates whether to allow multiple container assignments in one heartbeat.

yarn.scheduler.fair.resources-based-on-labels-enabled

Default Value: false

Description: Indicates whether to allow container allocation on all nodes by recomputing fair shares based on labels.

yarn.scheduler.fair.preemption.cluster-utilization-threshold-based-on-labels-enabled

Default Value: false

Description: Indicates whether to enable/disable preemption of the threshold per-label.

Fair Scheduler Allocation File

Describes an allocation file and the entities within an allocation file.

An allocation file is an XML manifest that describes queues and their properties, as well as certain policy defaults. The allocation file is automatically created during HPE Data Fabric installation in the following directory:

```
{$MAPR_HOME}/hadoop/hadoop-3.x/etc/hadoop/fair-scheduler.xml
```

The allocation file is reloaded every 10 seconds to refresh the scheduler with any modified settings that are specified in the file.

The allocation file contains the following types of elements:

Queue Elements

Queue elements represent queues and can contain the following elements:

- minResources
- maxResources
- maxRunningApps

TIP: The queueMaxAppsDefault value is used for any parent queue that does not set a value for the maxRunningApps element.

- weight

- `schedulingPolicy`
- `aclSubmitApps`
- `aclAdministerApps`
- `minSharePreemptionTimeout`
- `maxContainerAllocation`

TIP: The `maxContainerAllocation` property sets a limit on the resources a queue can allocate for a single container. The value cannot exceed `maxResources`. If you do not set `maxContainerAllocation`, the value is inherited from a parent queue. The default values are set through the `yarn.scheduler.maximum-allocation-mb`, `yarn.scheduler.maximum-allocation-vcores` properties, which you can modify in `/opt/mapr/hadoop/hadoop-3.x.x/etc/hadoop/yarn-site.xml`. The `maxContainerAllocation` element is not valid for the root queue.

For more information on these elements, see [Hadoop: Fair Scheduler](#).

User Elements

User elements represent settings that govern the behavior of individual users. They can contain a single property, `maxRunningApps`, which limits the number of running applications for a particular user. It contains the following elements:

- `userMaxAppsDefault`
- `queueMaxAppsDefault`
- `fairSharePreemptionTimeout`
- `defaultQueueSchedulingPolicy`
- `queuePlacementPolicy`

For more information on these elements, see [Hadoop: Fair Scheduler](#).

TIP: If you set a value for `queueMaxAppsDefault` and do not set a value for `maxRunningApps` for the root queue, the value of `queueMaxAppsDefault` sets the application limit for all queues under the root queue hierarchy.

Example Allocation File

See example allocation file in [Hadoop: Fair Scheduler](#).

Queue Access Control Lists

Queue Access Control Lists ([ACLs](#)) allow administrators to control who may take actions on particular queues. They are configured with the `aclSubmitApps` and `aclAdministerApps` properties, which can be set per queue. Currently, the only supported administrative action is killing an application. Anyone who has permission to administer a queue may also submit applications to it. These properties take values in a format such as `user1,user2 group1,group2` or `group1,group2`. An action on a queue is permitted if its user or group is in the [ACL](#) of that queue or in the [ACL](#) of any of that queue's ancestors. Therefore, if `queue2` is inside `queue1`, and `user1` is in `queue1`'s [ACL](#), and `user2` is in `queue2`'s [ACL](#), then both users may submit to `queue2`.

For more information, see [Hadoop: Fair Scheduler](#).

The `yarn.admin.acl` and `yarn.acl.enable` Properties

By default, on a secure cluster, users cannot kill jobs that do not belong to them.

On a secure cluster, you do not need to set the `yarn.acl` or the `yarn.admin.acl` properties. By default, they are set as follows. On unsecured clusters, these properties are not set by default.

```
<property>
  <name>yarn.acl.enable</name> >
  <value>true</value> >
</property>
<property>
  <name>yarn.admin.acl</name> >
  <value> </value> >
</property>
```

The `yarn.admin.acl` property is set by default to `" "`, meaning that an administrator is not specified on a cluster.

To allow users to kill jobs that do not belong to them, or to get access to their logs, you need to set the `yarn.admin.acl` property with the user or group name.

Fair and Capacity scheduler root queue admins

For both the Fair scheduler and Capacity scheduler, the default value of the administrators for the root queues is `" "`.

Hadoop 3.x Capacity Scheduler

The `CapacityScheduler` is a pluggable scheduler for Hadoop that allows multiple tenants to securely share a large cluster. Resources are allocated to each tenant's applications in a way that fully utilizes the cluster, governed by the constraints of allocated capacities.

Queues are typically set up by administrators to reflect the economics of the shared cluster. The Capacity Scheduler supports hierarchical queues to ensure that resources are shared among the sub-queues of an organization before other queues are allowed to use free resources.

The following sections provide more information about the `CapacityScheduler`:

Capacity Scheduler Features

The `CapacityScheduler` supports these features:

- **Hierarchical Queues** Hierarchical queues ensure that resources are shared among the sub-queues of an organization before other queues are allowed to use free resources, thereby providing more control and predictability.
- **Capacity Guarantees** Queues are allocated a fraction of the capacity of the grid, which means that a certain capacity of resources are at their disposal. All applications submitted to a queue have access to the capacity allocated to the queue. Administrators can configure soft limits and optional hard limits on the capacity allocated to each queue.
- **Security** Each queue has strict Access Control Lists (ACLs). The ACLs control which users can submit applications to individual queues. Also, safeguards ensure that users cannot view or modify applications from other users. Per-queue and system administrator roles are also supported.
- **Elasticity** Free resources can be allocated to any queue beyond its capacity allocation. As tasks scheduled on these resources complete, the resources become available to be reassigned to applications on queues running below their capacity. This ensures that resources are available in a predictable and elastic manner to queues, thus preventing artificial silos of resources in the cluster and improving cluster utilization.

- **Multi-tenancy** A comprehensive set of limits is provided to prevent a single application, user, or queue from monopolizing resources of the queue or the cluster as a whole. This ensures that the cluster is not overwhelmed.
- **Operability**
 - **Runtime Configuration** The queue definitions and properties, such as capacity or ACLs, can be changed in a secure manner by administrators at runtime, which minimizes disruption to users. Also, a console is provided for users and administrators to view the current allocation of resources to various queues in the system. Administrators can add queues at runtime, but queues cannot be deleted at runtime.
 - **Drain applications** Administrators can stop queues at runtime to ensure that while existing applications run to completion, no new applications can be submitted. If a queue is in the STOPPED state, new applications cannot be submitted to that queue or any of its child queues. Existing applications continue to completion, so the queue can be drained gracefully. Administrators can also start the stopped queues.
- **Resource-based Scheduling** Support for resource-intensive applications, where an application can optionally specify higher resource requirements than the default, thereby accommodating applications with differing resource requirements. Currently, *memory* is the only supported resource requirement.

Setting Up ResourceManager to Use CapacityScheduler

To configure the ResourceManager to use the CapacityScheduler, set the following property in the `yarn-site.xml` file:

Property Name	Value
<code>yarn.resourcemanager.scheduler.class</code>	<code>org.apache.hadoop.yarn.server.resourcemanager.scheduler.capacity.CapacityScheduler</code>

Setting Up Queues

The ResourceManager uses the configuration file `capacity-scheduler.xml`, where you can configure various scheduling parameters related to queues. These parameters include:

- the short queue name
- the full queue path name
- a list of associated child queues and applications
- the guaranteed capacity (expressed as a percentage of total resources in the cluster) available to the jobs in the queue
- the maximum capacity of the queue
- a list of active users and their resource allocation limits
- the state of the queue (running or stopped)
- access control lists that determine who can access the queue

The CapacityScheduler has a pre-defined queue called *root*. All queues in the system are children of the root queue. Further queues can be set up by configuring `yarn.scheduler.capacity.root.queues` with a list of comma-separated child queues.

Queue Properties

The `capacity-scheduler.xml` file includes three types of queue properties:

Resource Allocation Properties

The following table lists resource allocation properties:

Property	Description
yarn.scheduler.capacity.<queue-path>.capacity	<p>Queue <i>capacity</i> in percentage (%) expressed as a float (for example, 12.5). The sum of capacities for all queues, at each level, must equal 100.</p> <p>Applications in the queue may consume more resources than the queue's capacity if there are free resources, which provides elasticity.</p>
yarn.scheduler.capacity.<queue-path>.maximum-capacity	<p>Maximum queue capacity in percentage (%) expressed as a float.</p> <p>This property limits the elasticity for applications in the queue. The default is -1 which disables it.</p>
yarn.scheduler.capacity.<queue-path>.minimum-user-limit-percent	<p>Sets the minimum value, expressed as an integer, on the percentage of resources allocated to a user, if there is a demand for resources.</p> <p>A value of 100 implies no user limits are imposed. The default is 100.</p> <p>The maximum value depends on the number of users who have submitted applications. For example, if this property is set to 25 and two users have submitted applications to a queue, the maximum percent of queue resources for each user is 50%. If a third user submits an application, no single user can use more than 33% of the queue resources. With four or more users, no user can use more than 25% of the queue resources.</p>
yarn.scheduler.capacity.<queue-path>.user-limit-factor	<p>The multiple of the queue capacity that can be configured to allow a single user to acquire more resources.</p> <p>Value is specified as a float.</p> <p>The default is 1, which ensures that a single user can never take more than the queue's configured capacity no matter how idle the cluster is.</p>
yarn.scheduler.capacity.resource-calculator	<p>Specifies the ResourceCalculator implementation to be used to compare resources in the scheduler. The default value is DiskBasedResourceCalculator, which uses memory, CPU and disk. Other values for this parameter include:</p> <ul style="list-style-type: none"> DefaultResourceCalculator, which uses memory only DominantResourceCalculator, which uses dominant-resource to compare multi-dimensional resources such as memory and CPU DiskBasedDominantResourceCalculator, which uses dominant-resource to compare multi-dimensional resources, such as memory, CPU and disk

Running and Pending Application Limits

Applications are considered active if they are either running or pending. The following table lists properties that specify running and pending application limits:

Property	Description
yarn.scheduler.capacity.maximum-applications	<p>Maximum number of applications in the system that can be concurrently active, both running and pending.</p> <p>Limits on each queue are directly proportional to their queue capacities and user limits.</p> <p>This is a hard limit; any applications submitted when this limit is reached will be rejected. The default is 10000. This applies to all queues.</p>
yarn.scheduler.capacity.<queue-path>.maximum-applications	Overrides yarn.scheduler.capacity.maximum-applications on a per queue basis.
yarn.scheduler.capacity.maximum-am-resource-percent	<p>Maximum percent of resources in the cluster that can be used to run application masters - controls the number of concurrent active applications.</p> <p>Limits on each queue are directly proportional to their queue capacities and user limits. Specified as a float. For example, 0.5 = 50%.</p> <p>The default is 0.1. This can be set for all queues with yarn.scheduler.capacity.maximum-am-resource-percent</p>
yarn.scheduler.capacity.<queue-path>.maximum-am-resource-percent	Overrides yarn.scheduler.capacity.maximum-am-resource-percent on a per queue basis.

Queue Administration and Permissions

The following table lists queue administration and permission properties:

Property	Description
yarn.scheduler.capacity.<queue-path>.state	<p>The <i>state</i> of the queue. Possible values are RUNNING or STOPPED. If a queue is in the STOPPED state, new applications cannot be submitted to that queue or any of its child queues.</p> <p>If the <i>root</i> queue is STOPPED, no applications can be submitted to the entire cluster. Existing applications continue to completion, so the queue can be <i>drained</i> gracefully.</p>
yarn.scheduler.capacity.root.<queue-path>.acl_submit_applications	<p>The ACL that controls who can <i>submit</i> applications to the given queue. If the given user/group belongs to the ACL on a given queue or one of the parent queues in the hierarchy, they can submit applications.</p> <p>ACLs for this property are inherited from the parent queue if not specified.</p>
yarn.scheduler.capacity.root.<queue-path>.acl_administer_queue	<p>The ACL that controls who can <i>administer</i> applications on the given queue. If the given user/group has the necessary ACLs on the given queue or one of the parent queues in the hierarchy, they can administer applications.</p> <p>ACLs for this property are inherited from the parent queue if not specified.</p>

Setting Up a Hierarchy of Queues

CapacityScheduler uses a concept called a *queue path* to configure a hierarchy of queues. The queue path is the full path of the queue's hierarchy, starting at *root*. The following example has three top-level child-queues a, b, and c and some sub-queues for a and b:

Queue paths are defined for each level under the root queue. A queue's children are defined with the parameter `yarn.scheduler.capacity.<queue-path>.queues`, where `<queue-path>` takes the form `root.<child>`, `root.<child>.<child>`, and so on. For example, the queue path to `a2` is designated as `root.a.a2`.

WARNING:

Children do not inherit properties directly from the parent unless otherwise noted.

The corresponding queue definition block of the `capacity-scheduler.xml` file is shown below.

```

<property>
  <name>yarn.scheduler.capacity.root.queues</name>
  <value>a,b,c</value>
  <description>The queues at this level (root is the root queue).
</description>
</property>

<property>
  <name>yarn.scheduler.capacity.root.a.queues</name>
  <value>a1,a2</value>
  <description>The queues at this level (root is the root queue).
</description>
</property>

<property>
  <name>yarn.scheduler.capacity.root.b.queues</name>
  <value>b1,b2,b3</value>
  <description>The queues at this level (root is the root queue).
</description>
</property>
  
```

Changing Queue Configuration

You can change queue properties and add new queues by editing `capacity-scheduler.xml`. Make sure that the updated queue configuration is valid and that the queue-capacity at each level equals 100%.

For the changes to take effect, run the following command:

```
yarn radmin -refreshQueues
```

WARNING:

Queues cannot be deleted, only added.

Queue Access Control Lists

Describes how to restrict access to queues using Access Control Lists (ACLs).

Queue [ACLs](#) allow administrators to control who may take actions on particular queues. They are configured with the following properties:

```
yarn.scheduler.capacity.root.support.acl_submit_applications
yarn.scheduler.capacity.root.support.acl_administer_queue
```

You can set these properties for each queue. Currently, the only supported administrative action is killing an application. Anyone who has permission to administer a queue may also submit applications to it. These properties take values in a format such as `user1, user2 group1, group2` or `group1, group2`. An action on a queue is permitted if its user or group is in the [ACL](#) of that queue, or in the [ACL](#) of any of that queue's ancestors. So if queue2 is inside queue1, and user1 is in queue1's [ACL](#), and user2 is in queue2's [ACL](#), then both users may submit to queue2.

The root queue's [ACLs](#) are "*" by default. Since [ACL](#) are passed down, by default, everyone may submit to, and kill applications from every queue. To restrict access, change the root queue's [ACLs](#) to something other than *.

By default, the `yarn.admin.acl` property in `yarn-site.xml` is also set to *, which means that any user can be the administrator. If queue [ACLs](#) are enabled, you also need to set the `yarn.admin.acl` property to the correct admin user for the YARN cluster. For example:

```
<property>
<name>yarn.admin.acl</name> >
<value>mapr</value> >
</property>
```

If you do not set this property correctly, users can kill YARN jobs even when they do not have access to the queues for those jobs.

Label-based Scheduling

Label-based scheduling provides a way to allocate shared cluster resources on particular nodes in a cluster. First, you assign node labels in a text file. The node labels map to one or more nodes. Next, you can create queue labels and job labels based on the node labels.

When you run jobs, you can place them on specified nodes on a per-job basis (using a job label) or at the queue level (using a queue label). This feature is used in conjunction with schedulers, such as the Fair Scheduler or the Capacity Scheduler.

The following sections provide more information about label-based scheduling:

Label-based Scheduling for YARN Applications

Label-based scheduling provides job placement control on a multi-tenant hadoop cluster. Using label-based scheduling, an administrator can control exactly which nodes are chosen to run jobs submitted by different users and groups. This is useful for data locality and multi-tenancy use cases.

To use label-based scheduling, an administrator assigns node labels in a text file, then composes queue labels or job labels based on the node labels. When you run jobs, you can place them on specified nodes on a per-job basis (using a job label) or at the queue level (using a queue label).

This feature is used in conjunction with schedulers, such as the Fair Scheduler or the Capacity Scheduler.

YARN Resource Calculation Based on Labels

MapR 6.1.0 implements correct steady/instantaneous Fair Scheduler shares, headroom, and maximum resource calculation for queues with label-based scheduling (LBS).

This new approach to YARN resource allocation enables the cluster LBS configuration to compute the resources that are allowed for each queue. It also uses LBS to assign containers to the correct queues to preempt containers, and to prevent resource overuse. The LBS approach to YARN resource allocation relies on:

1. Resource computation (memory, CPU, disks) based on labels for each queue.
2. Per-label preemption threshold.

Example of LBS Resource Computation

For example, imagine that you have the following resources:

Using the former fair-share resource distribution results in the following:

Using the new LBS resource distribution results in the following:

Understanding LBS preemption thresholds

Before LBS, preemption occurred by default when an entire cluster became 80% full (`yarn.scheduler.fair.preemption.cluster-utilization-threshold=0.8f`). With LBS, preemption occurs per labeled resource, as that resource becomes 80% full.

Descriptions of New Properties When Using LBS

- `defaultQueueLabel`

Assigned to all new queues and existing queues that do not have a label (excluding the root queue).

For example, `root.%username%` queue is created if you submit a new job without queue information and property `yarn.scheduler.fair.user-as-default-queue` is true.

You can specify this property in `fair-scheduler.xml`:

```
<allocations>
  <defaultQueueLabel>LabelA</defaultQueueLabel>
  <queue name="root">
    ...
    <queue name="queue1">
      </queue>
    <queue name="queue2">
      <label>LabelB</label>
    </queue>
    ...
  </queue>
</allocations>
```

See [Specifying Fair Scheduler Configuration Properties in yarn-site.xml](#) on page 1909 for more information.

- `yarn.scheduler.fair.resources-based-on-labels-enabled`

Used to enable or disable recomputing of fair shares based on labels. It allows container allocation on all nodes.

You can specify this property in `yarn-site.xml`:

```
<property>
  <name>yarn.scheduler.fair.resources-based-on-labels-enabled</name>
  <value>>false</value>
</property>
```

- `yarn.scheduler.fair.preemption.cluster-utilization-threshold.based-on-labels-enabled`

Allows enabling or disabling (default) preemption of the threshold per-label. To overcome the default and start container preemption when the threshold of the label is exceeded, change this property to true.

You can specify this property in `yarn-site.xml`:

```
<property>
  <name>yarn.scheduler.fair.preemption.cluster-utilization-threshold.based-on-labels-enabled</name>
  <value>>false</value>
</property>
```

See [Specifying Fair Scheduler Configuration Properties in yarn-site.xml](#) on page 1909 for more information.

LBS Requirements and Restrictions?

Before you adopt LBS, you should be aware of two issues:

- Multiple labels for a node and label expression at the queue level are not supported.
- Except for root, all queues including the default, must be labeled, either independent or through inheritance.

Sample Cluster Configuration

To illustrate the concept of label-based scheduling, consider a cluster with two racks: RackA and RackB. The nodes in RackA are dedicated to the Production group, and the nodes in RackB are dedicated to the Development group. In addition, some nodes are configured with a fast CPU, one node is configured with high memory, and one node is configured with both a fast CPU and high memory. The following diagram illustrates the cluster configuration:

Using Node Labels to Schedule YARN Applications

About this task

To set up node labels for the purpose of scheduling YARN applications (including MapReduce applications) on a specific node or group of nodes:

Procedure

1. Enable the labels by using the following steps:
 - a. Add the `yarn.node-labels.enabled` parameter to the `yarn-site.xml` file:

```
<property>
  <name>yarn.node-labels.enabled</name>
  <value>true</value>
</property>
```

- b. Restart the ResourceManager (RM):

```
/opt/mapr/bin/maprcli node services -name resourcemanager -nodes
<node names> -action restart
```

2. Add labels to clusters and nodes:

```
yarn rmadm -addToClusterNodeLabels "label3, label4"
yarn rmadm -replaceLabelsOnNode "node3.cluster.com:8099=label3
node4.cluster.com:8099=label4"
```

3. To gather information about the labels, use any of the following commands:

- To list the node labels:

```
yarn cluster --list-node-labels
Node Labels: <label4:exclusivity=true>,<label3:exclusivity=true>
```

- To reload the queues, states, and scheduler-specific properties:

```
yarn radmin -refreshQueues
```

- To show the node status:

```
yarn node -status node3.cluster.com:8099
Node Report :
  Node-Id : node3.cluster.com:8099
  Rack : /default-rack
  Node-State : RUNNING
  Node-Http-Address : node3.cluster.com:8044
  Last-Health-Update : Tue 24/Jan/23 03:16:07:88UTC
  Health-Report :
  Containers : 0
  Memory-Used : 0MB
  Memory-Capacity : 45744MB
  CPU-Used : 0 vcores
  CPU-Capacity : 40 vcores
  Node-Labels : label3
  Node Attributes :
  Resource Utilization by Node : PMem:21544 MB, VMem:21544 MB,
VCores:2.6766665
  Resource Utilization by Containers : PMem:0 MB, VMem:0 MB,
VCores:0.0
```

Creating Queue Labels

Queue labels are optional with label-based scheduling. You can use queue labels to determine which nodes an application or job can run on (subject to the queue label policy). A queue label is created from node labels as explained below.

Defining Queue Labels for Fair Scheduler

Explains how to customize the Fair Scheduler.

By default, all users share a single queue, named *default*.

To customize the Fair Scheduler, create an allocation file that lists existing queues and their respective weights and capacities, as explained in [Hadoop 2.x Fair Scheduler](#). In the allocation file, add the following property within the queue section:

```
<label>labelname</label>
```

For example:

```
<queue name="Customer Data Analysis">
  <weight>2.0</weight>
  <label>Fast</label>
</queue>
```

For a hierarchical queue, note that labels and label policies can be defined on any level of the queue. If a child queue does not have its own labels or label policies, the labels and label policies of the closest level are used.

Defining Queue Labels for Capacity Scheduler

EEP 9.0.0 (core 7.1.0) and later use the Apache Hadoop node-label implementation.

For more information about label configuration for the capacity scheduler, see [Configuration of Schedulers for Node Labels](#).

Submitting Jobs and Applications to the Cluster

You can submit YARN applications (MapReduce version 2 and other applications that run on YARN) to the same cluster. An application can be submitted to the cluster in the following ways:

- The `hadoop jar` command submits an MRv2 application.
- The `yarn jar` command submits an application.
- An external application submits an application.
- An ecosystem component generates and submits an application.
- The `hadoop job` command submits an MRv2 application.
- The `mapred job` command submits an MRv2 application.

When you submit a non-MapReduce application to the cluster, such as a Spark application, it is automatically processed using `yarn` mode (ResourceManager, NodeManager, and MapReduce ApplicationMaster).

NOTE: The method to submit Hadoop commands from a Windows or Mac client is different, For details, see [Setting Up the Client](#).

Configuration Files for Jobs and Applications

Lists the locations of the MapReduce configuration files.

To override the MapReduce default configuration, use the following MapReduce configuration files:

MapReduce Version	Configuration File Locations
MapReduce Version 2	<ul style="list-style-type: none"> • <code>/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/mapred-site.xml</code> • <code>/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/yarn-site.xml</code>

To override the default configuration for applications, use the `yarn-site.xml` file that is present in `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop`.

YARN Container Resources

Provides an overview of YARN.

A YARN application can be a MapReduce version 2 (MRv2) application or a non-MapReduce application. The Warden on each node calculates the resources that can be allocated to process YARN applications. Each application has an ApplicationMaster that negotiates YARN container resources. For MapReduce applications, YARN processes each map or reduce task in a container. The ApplicationMaster requests resources from the ResourceManager based on memory, CPU, and disk requirements for the YARN containers. For YARN containers that process MRv2 tasks, there are additional considerations. See [YARN Container Resources for MapReduce Version 2 Applications](#) on page 1924 for details.

The ApplicationMaster requests YARN container resources based on the values of the following parameters:

yarn.scheduler.minimum-allocation-mb

Default: 1024

	<p><i>Description:</i> Defines the minimum memory allocation available for a container in MB.</p> <p>To change the value, edit the yarn-site.xml file for the node that runs the ResourceManager. Assign the new value to this property, then restart the ResourceManager.</p>
yarn.scheduler.maximum-allocation-mb	<p><i>Default:</i> 8192</p> <p><i>Description:</i> Defines the maximum memory allocation available for a container in MB.</p> <p>To change the value, edit the yarn-site.xml file for the node that runs the ResourceManager. Assign the new value to this property, then restart the ResourceManager.</p>
yarn.nodemanager.resource.memory-mb	<p><i>Default:</i> Variable. This value is calculated by Warden.</p> <p><i>Description:</i> Defines the memory available to processing Yarn containers on the node in MB.</p> <p>Warden uses the following formula to calculate this value: [total physical memory on node] - [memory required by the operating system, file system, and HPE Ezmeral Data Fabric services installed on the node].</p> <p>To determine the value, go to the ResourceManager UI and view the memory available for that node.</p>
yarn.nodemanager.resource.cpu-vcores	<p><i>Default:</i> Variable. This value is calculated by Warden.</p> <p><i>Description:</i> Defines the number of CPUs available to process YARN containers on this node.</p> <p>Warden uses the following formula to calculate this value: [Number of CPU cores on node] - [Number of CPU cores assigned to file system].</p> <p>To determine the value, go to the ResourceManager UI or the YARN pane on the Control System and view the number of CPUs available for that node.</p> <p>To change the value, edit the yarn-site.xml file for the node, assign the new value to this property, then restart the NodeManager.</p>
yarn.nodemanager.resource.io-spindles	<p><i>Default:</i> Variable. This value is calculated by Warden.</p> <p><i>Description:</i> Defines the number of disks available to process YARN containers. Warden uses the following formula to calculate this value: [Number of disks on the node].</p> <p>To determine the value, go to the ResourceManager UI or the YARN pane on the Control System and view the disk information for this node.</p>

YARN Container Resources for MapReduce Version 2 Applications

In addition to the YARN container resource allocation parameters, the MapReduce ApplicationMaster also considers the following container requirements when it sends requests to the ResourceManager for containers to run MapReduce applications:

Parameter	Default	Description
mapreduce.map.memory.mb	1024	Defines the container size for map tasks in MB.
mapreduce.reduce.memory.mb	3072	Defines the container size for reduce tasks in MB.
mapreduce.reduce.java.opts	-Xmx2560m --add-opens java.base/java.lang=ALL-UNNAMED -XX:+UseParallelGC	Java options for reduce tasks.
mapreduce.map.java.opts	-Xmx900m --add-opens java.base/java.lang=ALL-UNNAMED -XX:+UseParallelGC	Java options for map tasks.
mapreduce.map.disk	0.5	Defines the number of disks a map task requires. For example, a node with 4 disks can run 8 map tasks at a time. Note: If I/O intensive tasks do not run on the node, you may want to change this value.
mapreduce.reduce.disk	1.33	Defines the number of disks that a reduce task requires. For example, a node with 4 disks can run 3 reduce tasks at a time. Note: If I/O intensive tasks do not run on the node, you might want to change this value.

You can use one of the following methods to change the default configuration:

- Provide updated values in the `mapred-site.xml` file on the node that runs the job. You can use central configuration to change this value on each node that runs the NodeManager in the cluster. Then, restart NodeManager on each node in the cluster. The `mapred-site.xml` file for MapReduce applications is located in the following directory: `opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop`
- Override the default values from the command line for each application that requires a non-default value.

Monitoring the Cluster

This section describes how to monitor the health and performance of a MapR cluster.

Monitoring Using the Control System and the CLI

Describes the Overview page in the Control System, which displays information about the cluster.

The **Overview** displays a summary of information about the cluster in six panes including information on cluster health, activity, and usage.

NOTE: During installation using the Installer, you can configure metrics and logging using settings on the **Monitoring** page of the Installer user interface. The metrics collection infrastructure must be installed because the Control System relies on these metrics to provide graphs and charts in the **Overview** page. If the metrics collection infrastructure is not installed, you cannot visualize the metrics in the **Overview** page. If you want, you can install metrics collection or logging at any time by selecting the feature during an [Incremental Install](#).

The following sections provide information about each pane.

Setting the Refresh Rate on the Control System

Explains how to configure the user inactivity timeout setting, graph and data refresh settings from the Control System.

Setting Refresh Rate for Graphs and Data**About this task**

To set the refresh rate:

Procedure

1. Log in to the Control System and click **Settings** from the Profile and Settings  drop-down menu.
2. Enter the refresh rate in seconds for the following.

- Data refresh rate
- Metrics and charts refresh rate

The default refresh rate is 30 seconds. The minimum refresh rate is:

- 5 seconds for data.
- 30 seconds for metrics and charts.

3. Click **Save Changes** for the changes to take effect.

Setting Timer to End Session for Inactive User

Describes how to set the user inactivity timer to auto-terminate an inactive Control System user session.

About this task

User inactivity refers to the time that has elapsed since the last click on the web page was performed during an active user session.

If there is no user activity on the Control System for the specified time period during an active user session, the user is logged out of the Control System by an automatic termination of the user session.

The default value for the user inactivity timer is 30 minutes.

Follow the steps given below to configure the user inactivity timer:

Procedure

1. Log in to the Control System and click **Settings** from the Profile and Settings  drop-down menu.
2. Set the User Session Inactivity Timer in minutes.
3. Click **Save Changes** for the changes to take effect.

Results

The user session is automatically terminated and the user is logged out of the Control system, if the user does not operate the Control System for the specified time period during the current user session.

Customizing the List of Metric Charts and Columns on the Control System

Explains how to customize the list of metric charts and columns on the Control System.

About this task

You can customize the list of table metric charts and columns that you see on the Control System.

Creating a Custom Board for the Charts

About this task

To view a custom set of charts on the Control System, you can create a custom board. To create a board:

Procedure

1. Log in to the Control System and go to one of the following pages:
 - **Metrics** tab of the [node details page](#).
 - **Metrics** tab in the **Data > Tables** page.
 - **Metrics** tab of the [table information page](#).
 - **Metrics** tab of the [secondary index details page](#).
2. Select **Create new Board** from the **Boards** drop-down list to display the **Create New Chart Board** window.
3. Enter a unique name for the new Board in the **Board Name** field.
4. Select the charts from the **Available** list of charts and click  to move selection to **Selected** charts to display on page.
You can select up to six charts to display at a time on the page.
5. (Optional) Click  and/or down  arrows to sort the order of charts.
6. Click **Create and Apply** to create a new Board and view the selected charts in the Board.

Editing a Chart Board

About this task

You can modify an existing chart Board to add or remove charts from the board:

Procedure

1. Log in to the Control System and go to one of the following pages to view the board to modify:
 - **Metrics** tab of the [node details page](#).
 - **Metrics** tab in the **Data > Tables** page.
 - **Metrics** tab of the [table information page](#).
 - **Metrics** tab of the [secondary index details page](#).
2. Click  associated with the Board to modify from the **Boards** drop-down list.
The **Edit Chart Board** window displays.
3. You can make the following changes:
 - a) Modify the Board name.
 - b) Select the charts from the:
 - Selected list of charts and click  to remove selected charts.
 - Available list of charts and click  to move selection to **Selected** charts to display on page.

You can select up to six charts to display at a time on the page.

- c) Click  and/or down  arrows to sort the order of charts.

4. Click **Save and Apply** for the changes to take effect.

Removing a Chart Board

About this task

To remove charts from a Board, see [Editing a Chart Board](#) on page 1927. To remove a chart Board, do the following:

Procedure

1. Log in to the Control System and go to one of the following pages to view the list of Boards:
 - **Metrics** tab of the [node details page](#).
 - **Metrics** tab in the **Data > Tables** page.
 - **Metrics** tab of the [table information page](#).
 - **Metrics** tab of the [secondary index details page](#).
2. Click  associated with the Board to remove from the **Boards** drop-down list.
The **Delete Board** window displays.
3. Click **Submit** to remove the Board.

Adding and Removing Columns from the List View

Procedure

1. Log in to the Control System and do one of the following:
 - Go to the **Metrics** tab of the [node details page](#) and select **Activity by Tables** from the drop-down menu to view the metrics for all table-related activities on the node.
 - Go to the **Metrics** tab of the [table information page](#) and select:
 - **Activity by Nodes** (default selection) from the drop-down menu to view the metrics for table activity across nodes.
 - **Activity by Indexes** from the drop-down menu to view metrics for all index-related activity on the table.
 - Go to the **Metrics** tab of the [secondary index details page](#) and select **Activity by Nodes** to view metrics for index-related activity across nodes.
2. Click  to switch to a list view.
3. Click  to display the **Customize Columns** window.
In the **Customize Columns** window, the:
 - **Available** list displays the columns available, but currently not displayed.
 - **Selected** list displays the columns currently displayed in the page.
4. Select the columns from the:
 - a) Selected list of columns and click  to remove selected columns from the view.

- b) Available list of columns and click ➤ to move selection to **Selected** columns (for display).
For the list of metrics that can be viewed in the columns, see [Viewing Table Metrics in the Control System](#) on page 1945

5. (Optional) Click ▲ and/or down ▼ arrows to sort the order of columns.

6. Click **Save** to view the selected columns.

Monitoring the Cluster

Explains how to view the cluster health, disk, memory, CPU utilization metrics, and alarms on the cluster using either the Control System or the CLI.

Monitoring Cluster Health Using the Control System

Procedure

- Log in to the Control System and click **Overview**.

The **Overview** page displays the following panes:

- [Node Health](#) — the health of the nodes on the cluster, by service (default) or topology
- [Active Alarms](#) — a summary of active alarms for the cluster
- [Cluster Utilization](#) — CPU, memory, and disk space usage
- [Yarn](#) — the number of running and queued applications, number of Node Managers, and percent of memory and CPU's used relative to the amount configured

NOTE: During installation using the Installer, you can configure metrics and logging using settings on the **Monitoring** page of the Installer user interface. The metrics collection infrastructure must be installed because the Control System relies on these metrics to provide graphs and charts in the panes. If the metrics collection infrastructure is not installed, you cannot visualize the metrics in the various panes. If you want, you can install metrics collection or logging by selecting the feature during an [Incremental Install](#).

Viewing Cluster Utilization Information on the Control System

About this task

The **Cluster Utilization** pane in the **Overview** page displays the following for:

- CPU — Percentage of cores currently utilized and total cores
- Memory — Percentage of memory (in GB) currently utilized and total memory (in GB)
- Disk — Percentage of space (in GB) currently utilized and total disk space (in GB)

The **Cluster Utilization** pane also shows the amount of raw data and the savings (in percentage) after compression.

The **Utilization Trend** pane shows CPU, memory, and disk usage trend for the last 24 hours by default. You can select a preset (shown in the following screenshot) or specify a custom time range (shown in the following screenshot).

You can zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Reset Zoom** to zoom out and return to selected date/time range view. If there were any alarms during the selected date/time range, the **Alarms** pane above shows:

- When the alarm was raised
- The severity of the alarm

-  — an error
-  — a warning
-  — information

Monitoring Cluster Alarms on the Control System

About this task

See [Viewing Active Cluster Alarms](#) on page 1955 for more information.

Retrieving Cluster Information Using the CLI or REST API

About this task

The basic command to retrieve cluster health and disk space information is:

```
maprcli dashboard info -cluster <cluster>
```

The utilization field in the output shows the total and utilized amount of disk space, memory, and CPU for the cluster, which can also be visualized on the Control System. For example:

```
# /opt/mapr/bin/maprcli dashboard info -json
{
  "timestamp":1525230746268,
  "timeofday":"2018-05-01 08:12:26.268 GMT-0700 PM",
  "status":"OK",
  "total":1,
  "data":[
    {
      "utilization":{
        "cpu":{
          "util":7,
          "total":8,
          "active":0
        },
        "memory":{
          "total":15886,
          "active":11281
        },
        "disk_space":{
          "total":273,
          "active":0
        },
        "compression":{
          "compressed":0,
          "uncompressed":0
        },
        "tiering":{
          "logicalUsed":0,
          "replicatedLogicalUsed":0,
          "replicatedTotalUsed":0,
          "ecTotalUsed":0,
          "cvTotalUsed":0,
          "offloaded":0,
          "recalled":0
        }
      },
      ...
    }
  ]
}
```

```
}
]
}
```

For information on all the fields returned by this command, see [dashboard info](#) on page 2401.

Monitoring Nodes

Explains how to monitor nodes using either the Control System or the CLI.

About this task

You can check the health of the nodes on the cluster in the Control System, organized by service or by topology, or by using the CLI.

NOTE: To visualize the graphs and charts, you must install the metrics collection infrastructure during installation. If the metrics collection infrastructure is not installed, perform an [Incremental Install](#) to install the metrics collection infrastructure.

NOTE: The **Nodes** page is not available on the Kubernetes version of the Control System.

Monitoring Node Health Using the Control System

About this task

To monitor the health of nodes:

Procedure

1. Log in to the Control System and click:

- **Overview** to view the health of the nodes in the **Node Health** pane.
- **Nodes** to view the health of the nodes in the **Node Health** pane.

2. Select one of the following from the drop-down menu in the **Node Health** pane.

- **By Service** to organize the display of nodes by services.

This is the default view in the **Overview** page. This view contains the list of services and the nodes on which the service is running (■) and is down (■).

NOTE: The color of the node (which reflects the status of the service) is ■ even when a service is stopped (not running) on the node.

- **By Topology** to view the display of nodes by topology.

This is the default view in the **Nodes** page. This view contains the list of topologies and the health of the nodes (as shown in the following table) in the topology.

Node Color	Description
■	Indicates the node is healthy.
■	Indicates the node is degraded and/or may need attention. A node is considered to be in degraded state if: <ul style="list-style-type: none"> • There is no heartbeat from the HPE Data Fabric filesystem/NFS node for over 60 seconds. • One or more services are down on the node. • One or more alarms are raised on the node.

	Indicates the node is in maintenance mode.
	<p>Indicates critical issue(s) on the node. A node is considered to be in critical state if:</p> <ul style="list-style-type: none"> • There is no heartbeat from the node for more than 5 minutes. • All HPE Data Fabric files system disks on the node are dead or are offline. • All containers on the node are being re-replicated because either the node was removed, unregistered, or there was no heartbeat from the node for more than 1 hour. • File server is dead/inactive because there is no heartbeat for a long time. • NFS server on node is dead. • HPE Data Fabric install directory is full. • Node reported high HPE Data Fabric filesystem memory usage.

Monitoring Node Resource Utilization from the Control System

Procedure

- Log in to the Control System and click **Nodes** to view the nodes that consumed the most CPU and memory (in percentage) in the **Current Resource Utilization** pane. The shade of the bubble indicates node resource utilization with the darker shade indicating the nodes that are nearing disk capacity.

Monitoring Active Node Alarms from the Control System

About this task

See [Viewing Active Node Alarms](#) on page 1956 for more information.

Monitoring Node Health Using the CLI or REST API

About this task

You can check general health of the nodes with the following command:

```
maprcli node heatmap -cluster <cluster>
```

This command displays a heatmap for the nodes on the specified cluster; a subset of the output can also be visualized on the Control System. For complete reference information, see [node heatmap](#) on page 2568.

Viewing Node Metrics

Explains how to view node metrics using the Control System.

About this task

NOTE: The metrics collection infrastructure must be installed during installation to visualize the metrics in the various panes. If the metrics collection infrastructure is not installed, perform an [Incremental Install](#) to visualize the metrics that are described in the following section.

Monitoring Node Metrics Using the Control System

Procedure

- Log in to the Control System and go to the **Metrics** tab in the [node information page](#).

By default, the page displays charts that show metrics for the last 24 hours. You can select a preset or specify a custom time range.

Time Range

From:

2018-07-22 14:40

To:

2018-07-23 14:40

Apply

Last 2 days

Last 7 Days

Last 30 Days

Yesterday

Day before yesterday

This day last week

Previous week

Previous month

Today

Today so far

This week

This week so far

This month

This month so far

Last 5 minutes

Last 15 Minutes

Last 30 minutes

Last 1 Hour

Last 3 hours

Last 6 hours

Last 12 Hours

Last 24 Hours

You can also zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Zoom Out** to expand time window or click:

-  to shift time window forwards.
-  to shift time window backwards.

Click  associated with the chart to view information about the graph. Click  to display the **Customize Active Charts** window. You can select charts to display and remove from the **Available** and **Selected** lists in the **Customize Active Charts** window. You can view up to 6 charts at a time in the page.

Use the following table when selecting the charts to view in the page. In the following table, the Charts column lists the charts that are available and the Metric column describes that type of metric that can be visualized in the chart:

Metric	Charts
CPU Usage	<ul style="list-style-type: none">• Node Active CPU Usage• Node CPU Usage**• Node CPU Usage IDLE• Node CPU Usage NICE• Node CPU Usage SYSTEM• Node CPU Usage USER• Node CPU Usage WAIT• MFS CPU Usage• Allocated vs Available CPU Cores• MapR Process CPU Usage• MAST Gateway CPU Usage• DB Gateway CPU Usage• Data Access Gateway CPU Usage

Metric	Charts
Memory Usage	<ul style="list-style-type: none"> Node Free Memory Node Utilized Memory^{***} Node Memory Free vs Used* MFS Process Memory Usage Data Fabric Process Memory Usage
SWAP Space	<ul style="list-style-type: none"> Node Swap Free Node Swap Used Node Swap Space Available vs Used* Node Swap IO

System Disk Latency	<ul style="list-style-type: none"> Disk Avg Read Latency Disk Avg Write Latency Disk Read and Write Times
MFS Throughput	<ul style="list-style-type: none"> MFS Read Throughput MFS Write Throughput MFS Read and Write Throughput MFS System Disk Activity in Bytes*

* This metric is displayed in the default chart view for a node.

** This metric is displayed in the default chart view for a node and in the default list view for a table.

*** This metric is displayed in the default list view for a table.

For information on viewing metrics for:

- All table activities on a node, see [Viewing Per Node Metrics for Table Activities](#) on page 1935.
- All stream activities on a node, see [Monitoring Streams Operations Using the Control System](#) on page 1952.

Viewing Per Node Metrics for Table Activities

Describes how to view per node metrics for table activities using the Control System and Grafana.

About this task

This section describes how to view the metrics as charts and lists in the Control System. For information on visualizing the [metrics](#) in the Grafana UI, see [Metric Visualization](#) on page 2019

NOTE: The metrics collection infrastructure must be installed to visualize the metrics in the various panes. If the metrics collection infrastructure is not installed, perform an [Incremental Install](#) to visualize the metrics as described below.

Procedure

1. Log in to the Control System and go the **Metrics** tab in the [node information page](#).
2. Select **Activity by Tables** from the drop-down menu.

By default, the page displays charts that show metrics for the last 24 hours. You can select a preset or specify a custom time range.

You can also zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Zoom Out** to expand time window or click:

- to shift time window forwards.
- to shift time window backwards.

The charts show metrics for the node across tables. Click associated with the chart to view information about the graph. Click to display the **Customize Active Charts** window, where you can select charts to display and remove from the **Available** and **Selected** lists. You can view up to 6 charts at a time in the page.

You can switch to the list view by clicking . In the list view, you can:

- Click the table name to go to the metrics page for the table.
- Select one or more tables and switch to charts view (by clicking) to visualize metrics for the selected tables only.

For the complete list of metrics that you can view at both the node and table levels, see [Viewing Table Metrics in the Control System](#) on page 1945.

Monitoring YARN

Procedure

- Log in to the Control System and:

- Click **Overview** to view the following in the **YARN** pane:
 - Number of node managers, running applications, and queued jobs.
 - Memory and CPU utilization metrics.
- Go to the [service information page](#) for YARN. The YARN information page displays the following panes:

Summary

Displays:

- Total number of nodes and number of active and unhealthy nodes.
- Allocated, pending, and reserved number of Resource Manager containers.

Top Queues by CPU Utilization

Displays the queues that utilize the most CPU (in percentage).

Top Queues by Memory Consumption

Displays the queues that consume the most memory (in percentage).

Applications

Displays the number of submitted, completed, running, pending, and failed applications during a selected date and time range. You can select a preset or specify a custom time range.

Time Range		Last 2 days	Yesterday	Today	Last 5 minutes
From:		Last 7 Days	Day before yesterday	Today so far	Last 15 Minutes
	2018-07-22 14:40	Last 30 Days	This day last week	This week	Last 30 minutes
To:			Previous week	This week so far	Last 1 Hour
	2018-07-23 14:40		Previous month	This month	Last 3 hours
				This month so far	Last 6 hours
					Last 12 Hours
					Last 24 Hours
		Apply			

You can zoom in (by clicking and dragging the cursor in the pane) for a more granular view.

Resource Manager (CPU)

The number of cores allocated and used by Resource Manager during a selected date and time range. You can select a preset or specify a custom time range.

Time Range		Last 2 days	Yesterday	Today	Last 5 minutes
From:		Last 7 Days	Day before yesterday	Today so far	Last 15 Minutes
	2018-07-22 14:40	Last 30 Days	This day last week	This week	Last 30 minutes
To:			Previous week	This week so far	Last 1 Hour
	2018-07-23 14:40		Previous month	This month	Last 3 hours
				This month so far	Last 6 hours
					Last 12 Hours
					Last 24 Hours
		Apply			

You can zoom in (by clicking and dragging the cursor in the pane) for a more granular view.

Resource Manager (Memory)

The amount (in MB) of memory allocated and used by Resource Manager during a selected date and time range. You can select a preset or specify a custom time range.

Time Range		Last 2 days	Yesterday	Today	Last 5 minutes
From:		Last 7 Days	Day before yesterday	Today so far	Last 15 Minutes
	2018-07-22 14:40	Last 30 Days	This day last week	This week	Last 30 minutes
To:			Previous week	This week so far	Last 1 Hour
	2018-07-23 14:40		Previous month	This month	Last 3 hours
				This month so far	Last 6 hours
					Last 12 Hours
					Last 24 Hours
		Apply			

You can zoom in (by clicking and dragging the cursor in the pane) for a more granular view.

NOTE: The metrics collection infrastructure must be installed during installation to visualize the metrics in the various panes. If the metrics collection infrastructure is not installed, perform an [Incremental Install](#) to install the metrics collection infrastructure.

Monitoring Volumes

Explains how to monitor volume parameters using the Control System.

About this task

You can monitor volume:

- [Disk usage](#)
- [Alarms](#)

Monitoring Volume Disk Usage Using the Control System

Procedure

- You can view:
 - Volumes that use the most amount of allocated disk space in the **Top Volume Utilization** pane under **Data > Volumes**.

NOTE: The **Volumes** page is under the **Volumes** menu on the Kubernetes version of the Control System.

- Disk usage trend for a volume in the **Usage Trends** pane in the **Summary** tab of the [volume information page](#). You can select a preset (shown in the following screenshot) or specify a custom time range (shown in the following screenshot). You can zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Reset Zoom** to zoom out and return to selected date/time range view.

NOTE: The metrics collection infrastructure must be installed during installation to visualize the metrics in the various panes. If the metrics collection infrastructure is not installed, perform an [Incremental Install](#) to view the charts described here.

Monitoring Volume Alarms in the Control System

About this task

See [Viewing Active Volume Alarms](#) on page 1957.

Monitoring Local and Remote Storage for Volumes

About this task

You can view the following storage utilization metrics for tiered volumes in the **Data > Volumes > Local & Remote Usage** pane.

NOTE: The **Volumes** page is under the **Volumes** menu on the Kubernetes version of the Control System.

- **Local** — The total disk space (in GB) used (before compression) for the volumes in the HPE Data Fabric cluster. This value does not include erasure-coded backend volumes and cache-volumes because their logical usage is already accounted for by the front-end and parent volumes respectively.
- **Cold Offloaded** — The total physical data (in GB) offloaded to the cold tier. This is calculated using the following: *amount of data purged from the hot tier (HPE Data Fabric cluster) + amount of data recalled to the hot tier (HPE Data Fabric cluster)*.

- Warm Offloaded — The total physical data (in GB) offloaded to the erasure coded volume (warm tier). This is calculated using the following: *amount of data purged from the hot tier (HPE Data Fabric cluster)* + *amount of data recalled to the hot tier (HPE Data Fabric cluster)*.

Collecting Volume Metrics

Describes how to enable and collect operational metrics for volumes.

You can collect the following volume metrics on file system after you enable metrics collection as described in [Enabling Volume Metric Collection](#) on page 1939:

Read I/Os	Number of reads
Write I/Os	Number of writes
Read throughput	Amount of data read
Write throughput	Amount of data written
Read latency	Time taken by read operations
Write latency	Time taken by write operations

If you enable metrics collection on a volume, for each file system instance, on every node where the volume containers reside, metrics for the volume (for a day) are captured every 10 seconds and logged to files in a local volume, which is two way replicated. The metrics log file, `Metrics.log-<date>-<n>.json`, is available at `/var/mapr/local/<hostname>/audit/<mfs-port>` directory. Here:

- `mfs-port` is the port on which the file system instance listens.
- `date` is the record date in the format `yyyy-mm-dd`. A new file is created at the beginning of each day.
- `n` is the iteration of the log file represented by 3 digits. A new file is created every time Warden is restarted on the node. For the first file, `<n>` is 001 and `<n>` is incremented every time warden restarts. For example: `Metrics.log-2017-08-18-001.json` and `Metrics.log-2017-08-18-002.json`. When a new file is created, the old file is purged based on the CLDB audit log retention period, which is 30 days by default.

Each record in the file looks similar to the following:

```
{
  "ts":1503048590000,
  "vid":35211529,
  "RDT":0.0,
  "RDL":0.0,
  "RDO":0.0,
  "WRT":308085.8,
  "WRL":2434.0,
  "WRO":2192.0
}
```

Here:

- `ts` — timestamp in milliseconds
- `vid` — volume ID
- `RDT` — read throughput in KB (cumulative for 10 seconds)
- `RDL` — amount of time taken by read operations (average for 10 seconds)
- `RDO` — number of read operations (cumulative for 10 seconds)

- WRT — write throughput in KB (cumulative for 10 seconds)
- WRL — amount of time taken by write operations (average for 10 seconds)
- WRO — number of write operations (cumulative for 10 seconds)

The `collectd` service reads up to 16 MB of data every ten seconds from each file, then aggregates and writes one minute worth of data to OpenTSDB. When reading the file, the `collectd` service stores offsets (as to how much has been read) as extended attributes (`trusted.dispatchedOffset`) on the file. In addition to the default tags assigned to each metric when `collectd` writes metrics to OpenTSDB, the following tags are assigned to volume metrics:

- `mapr.volmetrics.[read_|write_][throughput|latency|ops]` — Displays the type of metric
- `volume_name` — Displays the name of the volume

For more information on the default tags, see [Metric Collection](#) on page 1963.

For each metrics file, Data Fabric also creates a file, `Vollist_metrics.log-<date>-<n>`, in the `/var/mapr/local/<hostname>/audit/<mfs-port>/` directory. This file is purged based on the CLDB audit log retention period, which is 30 days by default. This file contains a comma separated list of volume name and volume ID (for volumes for which metrics are captured) and is associated with the `Metrics.log-<date><n>.json` file. For example, the record in the file looks similar to the following:

```
<volumeid>,<volume name>,<volumeid>,<volume name>,...
```

You can visualize the metrics in the dashboards on Grafana. See [Metric Visualization](#) on page 2019 for more information.

Enabling Volume Metric Collection

Describes how to enable metric collection for a volume, and gather volume statistics.

About this task

On all new installations, this feature is enabled by default and you only need to enable metrics collection for each volume. If you are upgrading from a version prior to MapR version 6.0, to start collecting volume metrics that you can then visualize in Grafana, you must enable the metrics collection feature and then enable metrics collection for each volume.

You can enable metrics collection from the command-line and using the Control System.

Enabling the Metric Collection Feature

Procedure

- Enable the feature by running the following command:

```
/opt/mapr/bin/maprcli cluster feature enable -name  
mfs.feature.metrics.support
```

Enabling Metric Collection for New Volumes Using the Control System

Procedure

1. Log in to the Control System and click **Data > Volumes**.

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Click **Create Volume** to display the **Create New Volume** page.
3. Enter values for the required settings and move the slider for **Collect Metrics** to **Yes** to enable metric collection for the volume.
For more information, see [Creating a Volume](#) on page 1437.
4. Click **Create Volume** to create the volume.

Enabling Metric Collection for Existing Volumes Using the Control System

Procedure

1. Log in to the Control System and click **Data > Volumes**.

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Select the **Volumes** to edit and **Edit Volume** from the **Actions** drop-down menu or go the [volume info page](#) and click **Edit Volume**.
3. Move the slider for **Collect Metrics** to **Yes** to enable metric collection for the volume.
For more information, see [Creating a Volume](#) on page 1437.
4. Click **Save Changes** for the changes to take effect.

Enabling Metric Collection for Volumes Using the CLI

Procedure

- Enable metrics collection on:
 - A new volume by running the following command:

```
/opt/mapr/bin/maprccli volume create -name <volume-name> -path
<volume-mount-path> -type <volume-type> -metricsenabled true
```

For more information, see [volume create](#) on page 2929.

- An existing volume by running the following command:

```
/opt/mapr/bin/maprccli volume modify -name <volume-name> -metricsenabled
true
```

For more information, see [volume modify](#) on page 3018.

- All volumes that do not have mapr in the name by running the following script:

```
for i in ` /opt/mapr/bin/maprccli volume list -columns n | grep -v mapr |
grep -v volumename`; do echo $i; /opt/mapr/bin/maprccli volume
modify -name $i -metricsenabled true; done
```

Monitoring Tables

Explains how to monitor table alarms and view table metrics in the Control System.

Monitoring Table Alarms in the Control System

About this task

See [Viewing Active Table Replication Alarms](#) on page 1957.

Viewing Throughput by Operation Type Using the Control System

Procedure

- Log in to the Control System and do one of the following:
 - Go to the **Summary** tab in the [table information page](#).
 The **Throughput - By Op Type** pane displays a graph for the following operations on the table in the last hour:
 - Gets
 - Puts
 - Scans
 - Increments
 - Appends
 - Checks and Puts
 - Updates and Gets
 - Go to the **Summary** tab in the [index details page](#).
 The **Throughput - By Op Type** pane displays a graph for the following operations on the index in the last hour:
 - Puts
 - Scans

You can move the cursor over the graph to view the number of operations on the table (across nodes).

Visualizing Table Metrics in the Control System

About this task

In the Control System, you can visualize node-level metrics for table operations on a node. You can view charts that show metrics for all tables across all nodes, metrics per table aggregated across nodes, metrics per table per node, and metrics per node across tables. In addition, you can view metrics for activity by indexes and for the table and its secondary indexes.

For the full list of metrics (and associated charts/columns) that you can view in the Control System, see [Viewing Table Metrics in the Control System](#) on page 1945.

Procedure

- Log in to the Control System and do one of the following to view table metrics:
 - Go to the **Metrics** tab in the [node information page](#) and select **Activity by Tables** from the drop-down menu.

In this tab, you can view charts/columns that show metrics for all table operations on the node, operations on streams, and other node metrics described [here](#).

- Go to the **Metrics** tab in the **Data > Tables** page.

In this tab, you can view charts/columns that show metrics per node for all tables.

- Go to the **Metrics** tab in the [table information page](#).

In this tab, you can view charts/columns that show operations on the table and its secondary indexes across nodes.

- Go to the **Metrics** tab in the [index details page](#) and select **Activity by Nodes** from the drop-down menu.

In this tab, you can view charts that show all index operations and index operations per node.

You can select the charts to view by creating a custom chart Board or by modifying an existing Board. See [Creating a Custom Board for the Charts](#) on page 1927 or [Editing a Chart Board](#) on page 1927 for more information.

The charts on the page show the metrics for the last 24 hours by default. You can select a preset or specify a custom time range.

Time Range	
From:	2018-07-22 14:40
To:	2018-07-23 14:40
<button>Apply</button>	

Last 2 days	Yesterday	Today	Last 5 minutes
Last 7 Days	Day before yesterday	Today so far	Last 15 Minutes
Last 30 Days	This day last week	This week	Last 30 minutes
	Previous week	This week so far	Last 1 Hour
	Previous month	This month	Last 3 hours
		This month so far	Last 6 hours
			Last 12 Hours
			Last 24 Hours

You can also zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Zoom Out** to expand time window or click:

- to shift time window forwards.
- to shift time window backwards.

NOTE: When you select a granular view, the chart might not show the most accurate data because of the difference between the interval at which the metrics are logged and the downsampling (lowering the sampling rate) for the interval being viewed.

You can switch to a list view, where available, by clicking . In this view, you can select metrics to view by clicking . See [Adding and Removing Columns from the List View](#) on page 1928 for more information.

In the list view, you can:

- Filter the list by clicking .
- Click the node name to go to the node-level metrics page.
- Select one or more nodes and switch to charts view by clicking to visualize metrics for the selected nodes only. The legends for the charts reflect the selected nodes.

NOTE: Certain grouping of metrics, available in the charts view, are not available in the list view. All the metric grouping available in the list view are available in the charts view as well. When you switch from charts to list view and vice versa, your selection of metrics in one view is not carried over to the other view.

The chart and list views allow you to detect and diagnose bottlenecks and performance issues on individual tables and nodes. You can use the charts for measuring the throughput and latency of different RPC operations on a table and for determining which operations on a table are slow or which tables are most frequently accessed.

For example:

- Suppose your node is busy and you are noticing intermittent latency spikes on your table. You can compare throughput and latency in the **Metrics** tab of the [table information page](#) and investigate if the latency spike is due to node being very busy or node having high CPU utilization by switching to the list view from where you can navigate to the **Metrics** tab of the [node details page](#).
- Suppose your index queries take minutes instead of seconds to complete. You can compare the get latency percentile with the scan read/response in the **Metrics** tab of the [table information page](#) by zooming in to the area where you see the spike. Switch to **Activity by Index** to view the index vs primary table scans where you can determine whether excessive scan load went to the primary table.
- Suppose you are noticing latency spikes on one of your table as a result of a lot of activity on another table. Observe the get latency percentile spikes in the **Metrics** tab of the [table information page](#) and switch to **Activity by Node** list view to identify the nodes with high overall aggregate table RPC load and node IOps. Select the saturated nodes in the list view and switch to the chart view. Go back to the list view and click the saturated node to navigate to the **Metrics** tab of the [node details page](#). Switch to **Activity by Tables** to determine the most active table.

Viewing Secondary Index Metrics

About this task

You can visualize the secondary index metrics in the Control System.

Procedure

- Log in to the Control System and do one of the following:
 - Go to the **Metrics** tab in the [table information page](#) and select **Activity by Indexes** from the drop-down menu to view all index-related activity on the table.
 - Go to the **Metrics** tab in the [secondary index page](#) to view metrics for index-related activity across tables or per node.

By default, the page displays metrics for the last 24 hours. You can select a preset or specify a custom time range.

You can also zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Zoom Out** to expand time window or click:

- to shift time window forwards.
- to shift time window backwards.

The page displays charts by default. When viewing activity by nodes, you can switch to a list view by clicking and return to charts view by clicking .

Charts view

You can select the charts to view by creating a custom chart Board or by modifying an existing Board. See [Creating a Custom Board for the Charts](#) on page 1927 or [Editing a Chart Board](#) on page 1927 for more information. Click the associated with the chart to view information about the graph.

List view

The list view shows the metrics in the columns. You can customize the columns by clicking . See [Adding and Removing Columns from the List View](#) on page 1928 for more information. In addition, you can:

- Click the column name to sort the table by that column.
- Click the node name to go to the metrics page for the node.
- Click one or more checkboxes next to the node name and switch to the charts view to visualize metrics for the secondary index activities on those nodes only.

You can use the charts to diagnose and troubleshoot bottlenecks and performance issues. For the complete list of metrics that you can view for secondary indexes, see [Viewing Table Metrics in the Control System](#) on page 1945.

Viewing Region Distribution

Procedure

- Log in to the Control System and go to one of the following pages:
 - **Summary** tab in the [table information page](#) to view the region distribution for a table.
 - **Summary** tab in the [index details page](#) to view the region distribution for a secondary index.

The **Region distribution** pane shows the distribution of the table or secondary index regions across the nodes in the cluster. The shade of the node reflects the sum of the physical size of data on the node

with the darker shade indicating increased resource utilization on the node. You can move the cursor over a node to view the following:

- Hostname of the node
- Number of regions on the node
- Total size of data (across regions) on the node

You can click a node to go to the [node information page](#).

Viewing Table Metrics in the Control System

Explains how to view primary and secondary table index metrics using the Control System.

A subset of the following primary table and secondary index metrics are available as charts and lists in the Control System. For information on how to:

- View these metrics in the Control System, see [Monitoring Tables](#) on page 1940.
- Customize the charts you see on the page, see [Creating a Custom Board for the Charts](#) on page 1927.
- Customize columns you see on the page, see [Adding and Removing Columns from the List View](#) on page 1928.

Chart/Column Name	Metric	Description
Table Bytes Read Per Node	Throughput - bytes read	The number of bytes read from the primary table per node for all RPC types.
Table and Index Bytes Read		The number of bytes read across a primary table and its secondary indexes for all RPC types.
Table Bytes Written Per Node	Throughput - bytes written	The number of bytes written to the primary table per node for all RPC types.
Table and Index Bytes Written		The number of bytes written across a primary table and its secondary indexes for all RPC types.
Table Rows Read Per Node	Throughput - rowCount read	The number of rows read from the primary table per node for all RPC types.
Table and Index Rows Read		The number of rows read across a primary table and its secondary indexes for all RPC types. This is displayed in the default list view for a node.
Table Rows Written Per Node	Throughput - rowCount written	The number of rows written to the primary table per node for all RPC types.
Table and Index Rows Written		The number of rows written across a primary table and its secondary indexes for all RPC types.
All Tables Written Rows Throughput		Number of rows written by RPC operation type.

Chart/Column Name	Metric	Description
Table Rows Responded Per Node	Throughput - rowCount returned	The number of rows returned from the primary table per node for all RPC types.
Table and Index Rows Responded		<p>The number of rows returned across a primary table and its secondary indexes for all RPC types.</p> <p>This is displayed in the default list view for a node.</p>
Scan Throughput		<p>Compares the scan throughput for rows read versus rows returned.</p> <p>This is displayed in the default chart view for a node and for a table.</p>

Chart/Column Name	Metric	Description
All Tables Throughput	Throughput - rpcCount/second	Number of RPC operations by type for all tables in the cluster. This is displayed in the default chart view for all the tables.
Throughput by Rpc Type		The combined RPC load for the primary table and its indexes.
All Tables RPC Byte Throughput		The number of bytes processed by RPC operation type.
All Tables Read Rows Throughput		Number of rows processed by RPC operation type.
All Tables Returned Rows Throughput		Number of rows returned by RPC operation type.
Put and Append Operation Throughput		Number of put and append RPC operations for the table, including its indexes.
Table Check and Put Ops Per Node		The number of check and put operations completed for a primary table and for a node.
Table Update and Get Ops Per Node		The number of update and get operations completed for a primary table and for a node.
Table Get and Index Scans		The number of get and index scans completed for a primary table and for a node.
Table Write and Index Maintenance Activity		The number of table writes (puts, appends, increments, check and puts, update and gets) that require puts to the index.
Table Get Ops Per Node		The number of get operations completed for a primary table and for a node. This is displayed in the default list view for a node and for a table.
Table Get Throughput Per Node		The number of get operations completed per second for a table, excluding its secondary indexes, per node. This is displayed in the default chart view for a node and for a table.
Table Increment Ops Per Node		The number of increment operations completed for a primary table and for a node.
Table Put Ops Per Node		The number of put operations completed for a primary table and for a node. This is displayed in the default list view for a node and for a table.
Table Scan Ops Per Node		The number of scan operations completed for a primary table and for a node.
Table Append Ops Per Node		The number of append operations completed for a primary table and for a node.
Table Write Throughput Per Node		The number of put and append operations per second completed for

Chart/Column Name	Metric	Description
Table and Index Scan Latency	Latency	The 99th percentile latency of all scan operations across the primary table and its secondary indexes. A bad ratio between rows read and responded with high scan latency may indicate a poorly configured index.
Table and Index Scan Latency Per node		The 99th percentile latency of scan operations completed across the primary table and secondary index per node. Large scans may hit the disks and result in poor performance, or a degrading disk may spike the latency.
Table Append Latency Per Node		The 99th percentile latency of append operations on the primary table per node.
Table Increment Latency Per Node		The 99th percentile latency of increment operations on the primary table per node.
Table Put Latency Per Node		The 99th percentile latency of put operations on the primary table per node. This is displayed in the default list view for a node and for a table.
Table Get Latency Per Node		The 99th percentile latency of get operations on the primary table per node. This is displayed in the default list view for a node and for a table.
Table Scan Latency Per Node		The 99th percentile latency of scan operations on the primary table per node.
Table Get Latency Percentiles*		The get operation latency by percentile for the primary table and its secondary indexes.
Primary Table Put & Append Latency Percentiles*		The pure write operation latency by percentile for the primary table and its secondary indexes.
Table Write Throughput Latency Percentiles		The 99th percentile latency of put operations on the primary table per node. This is displayed in the default chart view for a node and for a table.
Table Get Throughput Latency Percentiles		The 99th percentile latency of get operations on the primary table per node. This is displayed in the default chart view for a node and for a table.
Table Check and Put Latency Per Node		The 99th percentile latency of check and put operations on the primary table per node.
Table Update and Get Latency Per Node		The 99th percentile latency of update and get operations on the primary table per node.
Index Put Latency		The 99th percentile latency of put operations per secondary index of the

Chart/Column Name	Metric	Description
All Tables Replication Sent Bytes	Replication - rows/bytes sent	The number of bytes of replication data sent.
All Tables Replication Pending Bytes	Replication - rows/bytes pending	The number of bytes of replication data not yet sent.
All Tables Replication Activity	Replication - rows/bytes sent/pending	Number of bytes of replication data sent vs not yet sent. This is displayed in the default chart view for all the tables.
Index Throughput by RPC Type	Index - Throughput	The combined RPC load for the primary table and its secondary indexes.
Index Put Ops		The number of put operations completed per secondary index of the primary table.
Index Put Ops Per Node		The number of put operations completed per secondary index of the primary table per node.
Index Scan Ops		The number of scan operations completed per secondary index of the primary table.
Index Scan Ops Per Node		The number of scan operations completed per secondary index of the primary table per node.
Index Bytes Read	Index - rows/bytes read	The number of bytes read per secondary index of the primary table for all RPC types.
Index Bytes Read Per Node		The number of bytes read per secondary index of the primary table per node for all RPC types.
Index Bytes Written Per Node		The number of bytes written per secondary index of the primary table per node for all RPC types.
Index Rows Read		The number of rows read per secondary index of the primary table for all RPC types.
Index Rows Read Per Node		The number of rows read per secondary index of the primary table per node for all RPC types.
Index Rows Responded	Index - rows/bytes returned	The number of rows returned per secondary index of the primary table for all RPC types.
Index Rows Responded Per Node		The number of rows returned per secondary index of the primary table per node for all RPC types.
Index Scan Read vs Returned Rows	Index - rows/bytes read	The number of secondary index rows that were read versus returned.

Chart/Column Name	Metric	Description
Index Bytes Written	Index - rows/bytes write	The number of bytes written per secondary index of the primary table for all RPC types.
Index Rows Written		The number of rows written per secondary index of the primary table for all RPC types.
Index Rows Written Per Node		The number of rows written per secondary index of the primary table per node for all RPC types.
All Tables Index Sent Bytes	Index - rows/bytes sent	The number of bytes sent for secondary index updates.
All Tables Index Pending Bytes	Index - rows/bytes pending	The number of bytes of secondary index data remaining to be sent.
All Index Maintenance Activity		Number of bytes of index data sent vs not yet sent. This is displayed in the default chart view for all the tables.
All Tables CDC Sent Bytes	CDC - rows/bytes sent	The number of bytes of CDC data sent.
All Tables CDC Pending Bytes	CDC - rows/bytes pending	The number of bytes of CDC data per node not yet sent.
All Tables CDC Propagation Activity		The number of bytes of CDC data sent vs not yet sent. This is displayed in the default chart view for all the tables.
All Streams Producer Ops	Streams Throughput, RPCs	The number of Streams producer RPCs.
All Streams Consumer Ops		The number of Streams consumer RPCs.
All Streams Producer Messages	Streams Throughput, messages	The number of Streams messages produced.
All Streams Consumer Messages		The number of Streams messages read by consumers.
Table Value Cache All Lookups	Value Cache Lookups	All operations for a primary table and for a node that performed a cache lookup.
Table Value Cache Lookups		The number of get operations for a primary table and for a node that performed a cache lookup.
Table Value Cache Lookups Per Index		The number of get operations for a primary table and for a node that performed a cache lookup.

Chart/Column Name	Metric	Description
Table and Index Value Cache All Lookups	Value Cache Hits	All operations across the primary table and its secondary indexes that performed a cache lookup.
Table and Index Value Cache Lookups Per Index		The number of get operations across the primary table and its secondary indexes that performed a cache lookup per secondary index.
Table and Index Value Cache Lookups		The number of get operations across the primary table and its secondary indexes that performed a cache lookup.
Table Value Cache All Hits		All operations for a primary table and for a node that resulted in a cache hit.
Table Value Cache Hits		The number of get operations for a primary table and for a node that resulted in a cache hit.
Table Value Cache Hits Per Index		The number of get operations for a primary table and for a node that resulted in a cache hit.
Table and Index Value Cache All Hits		All operations across the primary table and its secondary indexes that resulted in a cache hit.
Table and Index Value Cache Hits		The number of get operations across the primary table and its secondary indexes that resulted in a cache hit.
Table and Index Value Cache Hits Per Index		The number of get operations across the primary table and its secondary indexes that resulted in a cache hit per secondary index.
Value Cache Utilization	Value Cache	Compares the relative distribution of get operations that either hit the cache or require a lookup. This is displayed in the default chart view for a node and for a table.
All Tables Flushes	Bucket Flushes	The number of table flushes that were manually and automatically triggered. Table flushes reorganize data from bucket files (unsorted data) to spill files (sorted data) when the bucket size exceeds a threshold. This is displayed in the default chart view for all the tables.
All Tables Flushes		The number of total table flushes that were manually versus automatically triggered.
All Tables Force Flushes	Bucket Force Flushes	The number of table flushes that were not automatically triggered.

Chart/Column Name	Metric	Description
All Tables Compactions	Compaction	Number of table compactions. Compactions combine multiple HPE Data Fabric Database data files containing sorted data (known as spills) into a single spill file. This is displayed in the default chart view for all the tables.
All Tables Full Compactions		Number of full compactions. Compactions combine multiple HPE Data Fabric Database data files containing sorted data (known as spills) into a single spill file. Full compactions improve read performance because after compaction, HPE Data Fabric Database needs to read only the single resulting sorted spill file. But they incur I/O costs because the compaction must read, sort, and rewrite all data in the spill files.
All Tables Mini Compactions		Number of partial compactions. Compactions combine multiple HPE Data Fabric Database data files containing sorted data (known as spills) into a single spill file. After a mini compaction, HPE Data Fabric Database needs to read only two spill files.
All Tables TTL Compactions		Number of compactions that result in reclamation of disk space after removal of stale data. You can control the frequency of TTL compactions by configuring the TTL for a table's column families.
All Tables Free Index Memory	Memindex Usage	The number of available MB in the in-memory bucket file cache.

* Percentiles are estimated by linearly interpolating between fixed buckets sizes.

Monitoring Streams

Explains how to monitor streams using either the Control System or the CLI.

About this task

The speed at which messages flow from producers to partitions, and from partitions to consumers depends on the performance of your producers, the cluster nodes hosting partitions, and your consumers.

Monitoring Streams Operations Using the Control System

Procedure

- Log in to the Control System and go to the **Metrics** tab in the [node information page](#) to select the charts that show the following when you filter the list of charts by table activities:
 - All Streams Producer Messages:** The number of Streams messages produced on the node
 - All Streams Consumer Messages:** The number of Streams messages on the node read by consumers

- **All Streams Producer Ops:** The number of Streams producer RPCs on the node
- **All Streams Consumer Ops:** The number of Streams consumer RPCs on the node

For more information, see [Creating a Custom Board for the Charts](#) on page 1927.

Monitoring Active Stream Alarms

About this task

See [Viewing Active Stream Alarms](#) on page 1958.

Monitoring Cluster Nodes that Host Partitions

You can find out which nodes in a Data Fabric cluster are being used for topics in a stream by running the command `maprcli stream topic info`. The nodes are listed in the `servers` field.

The `guts` utility can show you whether there are any I/O bottlenecks on these nodes. This utility can also show you whether there is any capacity on other nodes in the cluster that you can take advantage of by creating additional partitions for topics.

To run this utility, issue this command after logging into the Data Fabric cluster that you want statistics for:

```
/opt/mapr/bin/guts
```

You can also use the `guts` utility to show only these statistics from HPE Data Fabric Streams:

Table

Name	Description
mpr	The number of RPCs from HPE Data Fabric Streams producers to the server.
mpm	The number of messages that have been published to the server.
mpMB	The total size in MB of the messages that have been published to the server.
mlr	The number of RPCs from HPE Data Fabric Streams consumers to the server.
mlm	The number of messages that have been read from the server.
mc l	The number of concurrent RPCs from consumers to the server.
mlMB	The total size in MB of the messages that have been read from the server.

To see these statistics, run this command:

```
/opt/mapr/bin/guts streams:all
```

NOTE: These statistics are for the most recent sample period at the time the command is run, and are not cumulative. Sample periods are one second.

Monitoring Producers

To get a sense of how quickly producers are sending messages to the producer client library, you can run the command `stream topic info` at intervals.

Doing so will show you changes over time in the rate at which the values for `maxoffset` and `maxtimestamp` increase for the partitions in the topics that your producers are publishing to.

For example, if you have a script that runs the command at intervals of 10 seconds, the change per second would be (Value at first run - Value at second run)/10.

This is an indirect measure of the speed of the producers because the producer client library batches messages before publishing them to partitions. The faster the producers send messages to the client, the faster the client publishes message batches, and the greater the change per second.

If producers do not seem to be sending messages quickly enough, and this problem is not caused by server-side I/O bottlenecks, you can spawn more producer threads.

See [stream topic info](#) for the syntax of this command.

Monitoring Consumers

There are two commands that you can run at intervals to get a sense of how far behind a consumer is in a partition. The consumer must belong to a consumer group, even if the consumer is the only member of that group.

To find the lag in milliseconds between the timestamp of the most recently published message in a stream, topic, or partition and the timestamp of a consumer's most recently committed cursor, run the command [stream cursor list](#). The lag is the value of the consumerlagmillis parameter.

To find the timestamp of the most recently committed cursor for the consumer that is furthest back in a partition compared to all other consumers reading from the same partition, run the command [stream topic info](#). This timestamp is the value of the mintimestampacrossconsumers parameter. Use this timestamp together with the values of the following parameters to get a sense of where this cursor is in the partition:

mintimestamp	This parameter shows the timestamp of the oldest message in the partition.
maxtimestamp	This parameter shows the timestamp of the most recently published message in the partition.

If a consumer's configuration for cursor commits is the default (the configuration parameter `enable.auto.commit` is set to `true` and `auto.commit.interval.ms` is set to 1000 milliseconds), the consumer will be only about one second ahead of the offset and timestamp reported for the consumer's most recently committed cursor.

If it seems that consumers are falling behind and that this problem is not caused by server-side I/O bottlenecks, you can start more consumer threads.

If the current number of consumers in a consumer group is equal to the number of partitions in the topic with the fewest partitions to which the consumer group is subscribed, add a partition to this topic before adding a consumer. The consumer client library dynamically reassigns the existing partitions in the topic to the consumers in the consumer group, as well as assigning the new partition to a consumer.

If the current number of consumers in a consumer group is less than the number of partitions in the topic with the fewest partitions to which the consumer group is subscribed, you don't need to add any partitions before adding a consumer.

Monitoring Alarms

Provides an overview of how to monitor alarms using the Control Panel and the CLI.

On a cluster with an Enterprise Edition or Enterprise Database Edition license, HPE Data Fabric raises alarms to alert you to information about the cluster:

- Cluster health, including disk failures
- Volumes that are under-replicated or over quota
- Services not running

You can see any currently raised alarms in the **Active Alarms** pane and the **Alarm Summary** page of the Control System (click  in the Control System) or using the [alarm list](#) on page 2298 command. For a list of all alarms, see the [Alarms Reference](#).

When you click , the **Alarm Summary** page displays all active alarms and for each alarm, the **All active alarms** pane displays the following:

Column Name	Column Description
Severity	The severity of the alarm. Value can be: <ul style="list-style-type: none">  — Critical  — Warning  — Information
Status	The status of the alarm. Value can be: <ul style="list-style-type: none"> Active Muted
Time	The date and time stamp from when the alarm was raised.
Name	The name of the alarm.
Info	The notes associated with the alarm, which contains description of the alarm and the recommended action to take.
Entity	The entity on which the alarm was raised.
Type	The type of alarm. Value can be: <ul style="list-style-type: none"> CLUSTER NODE VOLUME USER/GROUP

You can select the checkbox beside one or more alarms to:

- [Dismiss](#) the alarms
- [Mute](#) the alarms

Viewing Active Cluster Alarms

Describes how to view cluster alarms using the Control System and the CLI.

About this task

You can view cluster alarms using the Control System and the CLI.

Viewing Active Cluster Alarms in the Control System

Procedure

- Log in to the Control System and click:

- **Overview** to view all the alarms on the cluster in the **Active Alarms** pane. To view only the cluster alarms, select **Cluster Alarm** from the drop-down menu in the **Active Alarms** pane.
-  (Alarm Summary) to view all the alarms on the cluster in the **All** alarms pane. To view only the cluster alarms, select **Cluster Alarm** from the drop-down menu in the **All** alarms pane.

You can:

- [View](#) alarm information
- [Dismiss](#) an alarm
- [Mute](#) an alarm

Retrieving Cluster Alarms Using the CLI or REST API

About this task

The basic command to retrieve the alarms for a cluster is:

```
maprcli alarm list -cluster <cluster name> -type cluster
```

For complete reference information, see [alarm list](#) on page 2298.

Viewing Active Node Alarms

Describes how to view active node alarms using the Control System and the CLI.

Viewing Active Node Alarms in the Control System

Procedure

-  **NOTE:** The **Nodes** page is not available in the Kubernetes version of the Control System.
Log in to the Control System and:
 - Click **Nodes** to view all the node alarms on the cluster in the **Active Alarms** pane.
 - Go to the [node information page](#) to view alarms in the **Alarms** pane for the selected node.
 - Click  (in the top navigation bar) to display the **Alarm Summary** page and select **Node Alarms** from the drop-down menu in the **All** alarms pane.
 - Click **Overview** and select **Node Alarms** from the drop-down menu in the **Active Alarms** pane to view all the node alarms on the cluster.

You can:

- [View](#) alarm notes
- [Mute](#) an alarm
- [Dismiss](#) an alarm

Retrieving Active Node Alarms Using the CLI or REST API

About this task

The basic command to retrieve node alarms is:

```
maprcli alarm list -cluster <cluster name> -type node
```

For complete reference information, see [alarm list](#) on page 2298.

Viewing Active Volume Alarms

Describes how to view volume alarms using the Control System and the CLI.

About this task

You can view volume alarms in the Control System and using the CLI.

Viewing Active Volume Alarms in the Control System

Procedure

- Log in to the Control System and:
 - Click **Data > Volumes** to view all active volume alarms in the **Active Alarms** pane.
-  **NOTE:** The **Volumes** page is under the **Volumes** menu on the Kubernetes version of the Control System.
- Go to the **Summary** tab in the [volume information page](#) to view the recent and active alarms for the selected volume in the **Alarms** pane.
 - Click  (in the top navigation bar) and select **Volume Alarms** from the drop-down menu in the **All** alarms pane to view all the active volume alarms.
 - Click **Overview** and select **Volume Alarms** from the drop-down menu in the **Active Alarms** pane to view all active volume alarms.

You can:

- [View](#) information related to the alarm.
- [Dismiss](#) an alarm.
- [Mute](#) an alarm.

See [Volume Alarms](#) on page 3414 for more information on the volume alarms.

Retrieving Active Volume Alarms Using the CLI or REST API

About this task

The basic command to retrieve node alarms is:

```
maprcli alarm list -cluster <cluster name> -type volume
```

For complete reference information, see [alarm list](#) on page 2298.

Viewing Active Table Replication Alarms

Describes how to view active table replication alarms using the Control System and the CLI.

About this task

You can view table replication alarms using the Control System, the log files, and the CLI.

*Viewing Active Table Alarms in the Control System***Procedure**

- Log in to the Control System and click **Data > Tables** to view table replication alarms in the **Active Alarms** pane.

You can:

- [View](#) information related to the alarm.
- [Dismiss](#) an alarm.
- [Mute](#) an alarm.

See [Table-Replication Alarms](#) on page 3411 for more information on the table alarms.

*Retrieving Active Table Replication Alarms Using the CLI or REST API***About this task**

Alarms for replication are issued per volume rather than per source table. To retrieve table replication alarms, run the following command:

```
maprcli alarm list -cluster <cluster name> -type volume
```

For complete reference information, see [alarm list](#) on page 2298.

*Viewing Table Replication Alarms in the Log Files***About this task**

The log files `mf.s.log-5` and `cldb.log` display these alarms. These files are located in the `/opt/mapr/logs` directory.

Viewing Active Stream Alarms

Describes how to view active stream alarms using the Control System and the CLI.

About this task

You can view stream alarms using the Control System and the CLI.

*Viewing Active Stream Alarms in the Control System***Procedure**

- Log in to the Control System and:
 - Click **Data > Streams** to view all stream alarms in the **Active Alarms** pane.
 - Go to the **Summary** tab in the [stream information page](#) to view the recent and active alarms for the selected stream in the **Active Alarms** pane.

You can:

- [View](#) information related to the alarm.
- [Dismiss](#) an alarm.
- [Mute](#) an alarm.

See [Alarms Reference](#) on page 3392 for more information on the stream alarms.

*Retrieving Active Stream Alarms Using the CLI or REST API***About this task**

The basic command:

```
maprcli alarm list -cluster <cluster name> -type volume
```

For complete reference information, see [alarm list](#) on page 2298.

Monitoring Errors

Explains how to monitor errors using the Control System.

About this task

To view the errors on the cluster:

Procedure

1. Log in to the Control System and click  to display the **Recent Errors** window. The **Recent Errors** window displays only if there are any errors. For each error, the window displays the following:

Column Name	Column Description
Name	The name of the error.
Type	The type of error.
Action	The type of operation during which the error occurred.
Date & Time	The date and time when the error occurred.
Description	A brief description of the error.

2. Choose one of the following from the drop-down menu to filter the list of errors by a specific type:
 - All Types — to display all types of errors.
 - Data — to display errors related to data
 - Disk Usage — to display errors related to disk usage
 - Nodes — to display errors on nodes
 - Schedules — to display errors related to schedules
 - Services — to display service-related errors
 - Snapshots — to display errors during snapshot
 - Volumes — to display errors on volumes
 - Tables — to display errors on tables

Using HPE Data Fabric Monitoring (Spyglass Initiative)

HPE Data Fabric Monitoring (part of the Spyglass initiative) provides the ability to collect, store, and view metrics and logs for nodes, services, and jobs/applications.

Metric Monitoring

Administrators can monitor the current status of the cluster and anticipate future cluster requirements with dashboards. For example, you can use metrics dashboards to visualize the following:

Storage Utilization

Use metrics dashboards to monitor storage trends. For example, you can compare the volume of file system usage at different times to the file system capacity and then allocate resources to the file system accordingly.

Node Utilization

Use metrics dashboards to check for node overload. For example, if the CPU usage is high on a few nodes, you may want to distribute the load across more nodes for better performance and efficiency.

HPE Data Fabric Database Operational Trends

Use metrics dashboards to display historical trends for HPE Data Fabric Database operations. For example, if a user reports HPE Data Fabric Database slowness, the historical trends associated with row scans, get, and put operations can be used to identify the node(s) on which the performance degradation occurs.

Log Monitoring

Administrators can use dashboards to visualize, search, and review logs when troubleshooting issues. For example, you can use log dashboards to troubleshoot the following issues:

Service Failures

When metrics indicate that one or more services are down, use log dashboards to check the logs for each failed service and drill-down to each associated node.

Application Failures

When an application or job fails, use log dashboard to identify possible bottlenecks. For example, you can search the logs for a given application ID across all the nodes in the cluster.

file system Performance

When users experience file system or NFS for the HPE Data Fabric slowness, use log dashboards to search the HPE Data Fabric file system logs for service errors or application issues.

Related Information

- [Using HPE Data Fabric Monitoring \(Spyglass Initiative\)](#) on page 1959
- [Data Fabric Monitoring Storage Options](#) on page 87
- [Step 9: Install Metrics Monitoring](#) on page 274
- [Step 10: Install Log Monitoring](#) on page 277

HPE Data Fabric Monitoring Architecture

HPE Data Fabric Monitoring integrates with open-source components to collect, aggregate, store, and visualize metrics and logs.

NOTE: The HPE Data Fabric Monitoring architecture is designed for use on HPE Data Fabric cluster nodes. Installing monitoring components on client nodes or edge nodes is not supported.

Metric Monitoring Architecture

To visualize cluster metrics, HPE Data Fabric Monitoring integrates with the following components:

**collectd**

The collectd service runs on each node in the cluster to collect metrics. It uses streams to send the metrics to opentsdb. For more information, see [Metric Collection](#) on page 1963.

OpenTSDB

OpenTSDB aggregates the metrics and runs as the time-series database on top of HPE Data Fabric Database, the metrics data store. Based on your cluster requirements, it runs on one or more nodes in the cluster.

Grafana

Grafana uses REST API to access metrics data from OpenTSDB. Using a single instance of Grafana, users can build custom dashboards or use sample dashboards to visualize the metric. For more information about dashboards, see [Metric Visualization](#) on page 2019.

Log Monitoring Architecture

To visualize logs, Data Fabric Monitoring integrates with the following components:

fluentd	fluentd runs on each node in the cluster to collect and parse logs. It uses REST API to send the logs to ElasticSearch. For more information, see Log Collection on page 2024.
Elasticsearch	Elasticsearch indexes the logs so that they are easily accessed and searchable. Based on your cluster requirements, it runs on one or more nodes in the cluster. For more information, see Log Aggregation and Storage on page 2029.
Kibana	Kibana uses REST API to access and search the logs available in Elasticsearch. Using a single instance of Kibana, users can create visualizations and dashboards to analyze their logs. For more information, see Log Visualization on page 2034.

Spyglass on Streams

Release 6.0 of the HPE Data Fabric introduced Spyglass on Streams. When you install release 6.0 or later, Streams is the default mechanism through which metrics flow from the Collectd service to OpenTSDB. Moving metrics through streams secures the data and provides a mechanism to perform real-time data analytics.

NOTE: Currently, Spyglass on Streams is not available for logs. Fluentd continues to use the REST API to send logs to ElasticSearch for the indexing of logs.

The Flow of Metrics via Streams

The Collectd service collects node-level and service-level metrics from each node in the cluster. The Collectd service hashes metrics to a stream and writes the metrics into topics in that stream.

In release 6.1.0 and later, Collectd creates one stream per cluster: `/var/mapr/mapr.monitoring/metricstreams/0`. Topic names use the format `<hostname>`. For example: `mfs81.qa.lab`.

The Streams server distributes metrics to the available OpenTSDB nodes, and OpenTSDB consumes the metrics.

NOTE: Writing to an external OpenTSDB is not supported from release 6.0 onwards. In addition, inserting non Data Fabric data into the provided OpenTSDB is not supported. Any custom data added to the provided OpenTSDB will be removed by the purge script (`tsdb_cluster_mgmt.sh`) that runs periodically.

NOTE: Dedicated metrics volumes should be appropriately paired with a topology that has OpenTSDB nodes. Change topology accordingly if OpenTSDB begins using more than 10% of the file-system write capacity.

Determining How Many OpenTSDB Nodes to Install

Having multiple OpenTSDB nodes in the cluster distributes the workload. The number of partitions and OpenTSDB nodes determines the level of parallelism for consumption.

Each OpenTSDB node can consume one partition at a time. By default, metrics data is divided across 12 partitions in each topic and optimal parallelism is reached if there are five OpenTSDB nodes to consume the partitions. See [Parallelism When Consuming Messages](#). Note that the term “consumer” in the topic equates to an OpenTSDB node in Spyglass on Streams.

A general guideline for the minimum number of OpenTSDB nodes in a cluster is one for every 10x increase in nodes beyond 10, for example:

- Three OpenTSDB nodes in a 10-node cluster
- Four OpenTSDB nodes in a 100-node cluster

- Five OpenTSDB nodes in a 1000-node cluster

If your cluster has 10 or more nodes, at least three OpenTSDB nodes should be available to consume metrics. Typically, for every 10x increase in nodes, you should add another OpenTSDB node. For example, if your cluster reaches a size of 100 nodes, have four OpenTSDB nodes available for consumption.

These guidelines do not guarantee optimal performance. Evaluate the performance of the streams to determine if your cluster would benefit from additional OpenTSDB nodes.

NOTE: If all configured OpenTSDB nodes have been offline for several hours, you may notice an initial spike in memory and CPU usage by OpenTSDB processes as they aggressively try to keep up with the metrics. You can reduce the number of AsyncHBase threads to reduce the CPU and memory usage. By default, AsyncHBase runs 128 threads. To modify the number of threads, add or modify the following property in the `/opt/mapr/asynchbase/asynchbase-
<version>/conf/asynchbase.conf` file on the OpenTSDB nodes:

```
"fs.mapr.async.worker.threads=<value>"
```

Increasing the Number of Streams

For release 6.1 and later, the default setting for the number of streams is one. Even if your cluster grows to 1000 nodes or more, you do not need to increase the number of streams. For release 6.0.x, increasing the number of streams is recommended as you add more nodes (see the release 6.0 documentation), but this practice is not required in release 6.1 and later.

Changing the Automatic Stream Cursor Commits

You can adjust the frequency of automatic stream cursor commits for OpenTSDB. Modify the `tsd.streams.autocommit.interval` in `opentsdb.conf`. The unit is thousands of seconds. The default value is '60000' which is 60 secs. For a system with heavy loads, consider changing the value to something like 5 minutes.

Metric Collection

Metrics are collected from each node in the cluster so that administrators can use the data to monitor the cluster. In general, the `collectd` service collects metrics every 10 seconds. The exception is volume metrics which are collected every 10 minutes.

When `collectd` writes metrics to streams, tags are assigned to each metric so that administrators can filter metric data to create dashboards that are specific to their needs.

By default, each metric contains the following tags:

- `fqdn`: Displays values for a specified node.
- `clusterid`: Displays values for a specific cluster.
- `clustername`: As of EEP 3.0, displays values for a specific cluster.

However, many metrics have additional tags that you can use to filter metric data.

Streams store metrics in OpenTSDB with the following schema:

```
<metrictype.name> <fqdn:fqdnvalue> <clusterid:clusteridvalue>  
<clustername:clusternamevalue>[<AdditionalTagA:AdditionalTagAvalue>  
<AdditionalTagB:AdditionalTagBvalue>...] <metricvalue> <timestamp>
```

NOTE: A negative value shown in the metrics indicates that the maximum value configured for that metric is exceeded. The maximum value for GUT metrics is `int32 (2^31-1)`.

For more information on using tags and dashboards, see [Metric Visualization](#) on page 2019.

Configure Metric Retention

By default, OpenTSDB stores two weeks of metrics. Based on your requirements, you can change the metric-retention period.

The following cron job runs each day to purge metrics based on the retention period:

```
$min $hour * * * $OTSDB_HOME/bin/
tsdb_cluster_mgmt.sh -purgeData -retentionPeriod '2 weeks ago'
```

To edit the metric-retention period:

1. Depending on the operating system, use `crontab -e` as the cluster admin (typically `mapr`) user, or open a crontab file:

- For RHEL:

```
"/var/spool/cron/$MAPR_USER"
```

- For SLES:

```
"/var/spool/cron/tabs/$MAPR_USER"
```

- For Ubuntu:

```
"/var/spool/cron/crontabs/$MAPR_USER"
```

2. In the following line, update the value of '2 months ago' to the new retention period. You can use any format accepted by the `date --date=command`, such as '2 months ago' or '2 days ago'. For example:

```
27 5 * * * /opt/mapr/opentsdb/opentsdb-2.4.1/bin/
tsdb_cluster_mgmt.sh -purgeData -retentionPeriod '2 months ago'
```

To delete metrics from 1/1/2000 to [current date - 2 days]:

```
27 5 * * * /opt/mapr/opentsdb/opentsdb-2.4.1/bin/
tsdb_cluster_mgmt.sh -purgeData -retentionPeriod '2 days ago'
```

WARNING: Data Fabric monitoring uses 2 MB of disk space per minute per node when HPE Data Fabric Streams metrics are enabled. This is approximately 3 GB per day on a single node or 7 GB per node per day with 3X replication. This streams metrics data is automatically deleted every three days.

If openTSDB is down for more than three days, you may lose the metric data.

NOTE: For more information, see the [OpenTSDB scan command documentation](#).

Configure Queue Filters for `mapr.rm.<value> Metrics`

The YARN application metrics that are collected by JMX have the metric name syntax `mapr.rm.<metric_name>` and the metric values are aggregated among all the queues in the default queue. However, you can configure `collectd` to create a filter for each queue. As an alternative, you can use the REST API queue metrics (`mapr.rm_queue.<metric_name>`) which are by default set up for filtering by queue.

About this task

To configure collectd to create queue filters for `mapr.rm.*` metrics, define each queue that you want to create filters for in the `/opt/mapr/collectd/collectd-<version>/etc/collectd.conf` file. You can configure collectd to generate filters for every queue or only for specific queues. Changes that you make to the `collectd.conf` file only apply to metrics collected after you restart the collectd service.

Procedure

1. Open the `collectd.conf` file and locate the MBean "QueueMetrics" block.

```
<MBean "QueueMetrics">
  ObjectName
  "Hadoop:service=ResourceManager,name=QueueMetrics,q0=root"
  InstancePrefix "rm"

  <Value "AppsRunning">
    Type "apps_running"
    InstancePrefix "default-queue"
  </Value>

  <Value "ActiveApplications">
    Type "active_applications"
    InstancePrefix "default-queue"
  </Value>

  ...
</MBean>
```

This block specifies that there is one queue named `root` and that the filter for this queue is named `default-queue`.

2. Create copy of the MBean "QueueMetrics" block.
3. Configure the `ObjectName` option in the MBean "QueueMetrics" block copy, with the queue path for the queue that you want to create a filter for.
 - To define the a child queue named `alpha` under the `root` queue:

```
ObjectName
"Hadoop:service=ResourceManager,name=QueueMetrics,q0=root,q1=alpha"
```

- To define a child queue named `beta` which is under a child queue named `alpha`:

```
ObjectName
"Hadoop:service=ResourceManager,name=QueueMetrics,q0=root,q1=alpha,q2=beta"
```

4. For each `Value` block within the MBean "QueueMetrics" block you are defining, replace `default-queue` with the queue name that you want to create a filter for.

- To define filter value alpha for the rm_queue tag, set the InstancePrefix to alpha:

```
<MBean "QueueMetrics">
  ObjectName
  "Hadoop:service=ResourceManager,name=QueueMetrics,q0=root,q1=alpha"
  InstancePrefix "rm"
  <Value "AppsRunning">
    Type "apps_running"
    InstancePrefix "alpha"
  </Value>
  <Value "ActiveApplications">
    Type "active_applications"
    InstancePrefix "alpha"
  </Value>
  ...
</MBean>
```

- To define a filter value beta for the rm_queue tag, set the InstancePrefix to beta::

```
<MBean "QueueMetrics">
  ObjectName
  "Hadoop:service=ResourceManager,name=QueueMetrics,q0=root,q1=alpha,q2=b
eta"
  InstancePrefix "rm"
  <Value "AppsRunning">
    Type "apps_running"
    InstancePrefix "beta"
  </Value>
  <Value "ActiveApplications">
    Type "active_applications"
    InstancePrefix "beta"
  </Value>
  ...
</MBean>
```

- Repeat steps 2 and 3 for each queue that you want to create a filter value for.
- Save the collectd.conf file.
- Repeat steps 1 through 6 on each ResourceManager node.
- Restart the collectd service.

```
maprcli node services -name collectd -nodes <space separated list of
ResourceManager Nodes> -action restart
```

Example

In the following example, rm_queue tag will have the following filter values: alpha, beta (child of alpha), and highpriority (child of root):

```
<MBean "QueueMetrics">
  ObjectName "Hadoop:service=ResourceManager,name=QueueMetrics,q0=root
q1=alpha"
  InstancePrefix "rm"

  <Value "AppsRunning">
    Type "apps_running"
    InstancePrefix "alpha"
  </Value>
```

```

    <Value "ActiveApplications">
      Type "active_applications"
      InstancePrefix "alpha"
    </Value>
    ...
    <Value "ReservedVCores">
      Type "reserved_vcores"
      InstancePrefix "alpha"
    </Value>
  </MBean>

<MBean "QueueMetrics">
  ObjectName "Hadoop:service=ResourceManager,name=QueueMetrics,q0=root
q1=alpha q2=beta"
  InstancePrefix "rm"

  <Value "AppsRunning">
    Type "apps_running"
    InstancePrefix "beta"
  </Value>

  <Value "ActiveApplications">
    Type "active_applications"
    InstancePrefix "beta"
  </Value>
  ...
  <Value "ReservedVCores">
    Type "reserved_vcores"
    InstancePrefix "beta"
  </Value>
</MBean>

<MBean "QueueMetrics">
  ObjectName "Hadoop:service=ResourceManager,name=QueueMetrics,q0=root
q1=highpriority"
  InstancePrefix "rm"

  <Value "AppsRunning">
    Type "apps_running"
    InstancePrefix "highpriority"
  </Value>

  <Value "ActiveApplications">
    Type "active_applications"
    InstancePrefix "highpriority"
  </Value>
  ...
  <Value "ReservedVCores">
    Type "reserved_vcores"
    InstancePrefix "highpriority"
  </Value>
</MBean>

```

Configure the Collectd Service Heap Size

The collectd service uses an embedded JVM when it gathers metrics from the CLDB, Node Manager, Resource Manager, and Drill. You can edit the Plugin Java section of *collectd.conf* to configure limits to the collectd virtual memory footprint.

About this task

NOTE: The Plugin Java section of the collectd.conf file may be commented or uncommented. The [configure.sh](#) utility will uncomment the Plugin Java section when collectd runs on a node that requires an embedded JVM. Therefore, when you update the file, do not add or remove comment symbols (#) in the Plugin java section

Complete the following steps on each collectd node:

Procedure

1. Open the /opt/mapr/collectd/collectd-<version>/etc/collectd.conf file.
2. Look for the following section:

```
## **** MAPR_CONF_JMX_TAG: MAPR CONFIGURATION - DO NOT EDIT or REMOVE
TAG/BLOCK ***
<Plugin java>
JVMArg "-Djava.class.path=....."
```

3. Update Xms and Xmx options in the Plugin java section.

Xms defines the amount of memory allocated to the service when it starts. Xmx defines the maximum amount of memory allocated to the service.

If the <Plugin java> section is not commented out, the configuration may look like this:

```
## **** MAPR_CONF_JMX_TAG: MAPR CONFIGURATION - DO NOT EDIT or REMOVE
TAG/BLOCK ***
<Plugin java>
JVMArg "-Djava.class.path=....."
JVMArg "-Xms32m"
JVMArg "-Xmx128m"
```

If the <Plugin java> section is commented out, the configuration may look like this:

```
### **** MAPR_CONF_JMX_TAG: MAPR CONFIGURATION - DO NOT EDIT or REMOVE
TAG/BLOCK ***
#<Plugin java>
# JVMArg "-Djava.class.path=....."
# JVMArg "-Xms32m"
# JVMArg "-Xmx128m"
```

4. Restart the collectd service.

```
maprcli node services -name collectd -nodes <space separated list of
hostname/IPaddresses> -action restart
```

CPU Metrics

Every 10 seconds, the collectd service uses the cpu plugin to gather the following CPU metrics on each node in the cluster.

Name	Description	Additional Tag(s)
cpu.percent	The aggregate percentage of all CPUs.	<ul style="list-style-type: none"> cpu_core: Display values specified core. Core values: 0,1, and 2 cpu_class: Display values for a specified class of CPU. CPU class values: idle, user, nice, system.
thread.cpu_usage	The percentage of CPU used by each thread.	<ul style="list-style-type: none"> thread_name: Indicates if thread belongs to RPC, HPE Data Fabric Database, file system, or an instance of file system.

Disk Free Metrics

Every 10 seconds, the collectd service uses the df plugin to gather the following disk free metrics on each node in the cluster.

Name	Description	Additional Tag(s)
df.df_complex	The aggregate number of bytes for disk partitions.	<ul style="list-style-type: none"> df_partition: Display values for a specified disk. Disk values: dev or boot. df_type: Display values for a certain type. Type values: free, reserved, and used.
df.percent_bytes	The aggregated percentage of disk partitions.	<ul style="list-style-type: none"> df_partition: Display values for a specified disk. Disk values: dev or boot. df_type: Display value for a certain type. Type values: free, reserved, and used.

Disk Metrics

Every 10 seconds, the collectd service uses the disk plugin to gather the following disk metrics on each node in the cluster.

Name	Description	Additional Tag(s)
disk.disk_await	The average time in milliseconds to complete I/O requests. This includes the time request are waiting in queue and the time spent processing the request. This metric is available as of EEP 3.0.	<ul style="list-style-type: none"> disk_name: Display values for a specified disk.
disk.disk_avg_requests_size	The average size in kilobytes for I/O requests issued to the disk. This metric is available as of EEP 3.0.	<ul style="list-style-type: none"> disk_name: Display values for a specified disk.
disk.disk_avg_queue_size	The average number of requests issued to the disk. This metric is available as of EEP 3.0.	<ul style="list-style-type: none"> disk_name: Display values for a specified disk.
disk.disk_io_time.io_time	The disk I/O time in milliseconds (ms).	<ul style="list-style-type: none"> disk_name: Display values for a specified disk.

Name	Description	Additional Tag(s)
disk.disk_io_time.weighted_io_time	The aggregate time in milliseconds (ms) spent on I/O operations that are either in progress or have completed	<ul style="list-style-type: none"> disk_name: Display values for a specified disk.
disk.disk_merged.read	The number of physical read operations.	<ul style="list-style-type: none"> disk_name: Display values for a specified disk.
disk.disk_merged.write	The number of physical write operations.	<ul style="list-style-type: none"> disk_name: Display values for a specified disk.
disk.disk_octets.read	The number of bytes read from disk.	<ul style="list-style-type: none"> disk_name: Display values for a specified disk.
disk.disk_octets.write	The number of bytes written to disk.	<ul style="list-style-type: none"> disk_name: Display values for a specified disk.
disk.disk_ops.read	The number of completed read operations.	<ul style="list-style-type: none"> disk_name: Display values for a specified disk.
disk.disk_ops.write	The number of completed write operations.	<ul style="list-style-type: none"> disk_name: Display values for a specified disk.
disk.disk_time.read	The average time in milliseconds(ms) to read from disk.	<ul style="list-style-type: none"> disk_name: Display values for a specified disk.
disk.disk_time.write	The average time in milliseconds(ms) to write to disk.	<ul style="list-style-type: none"> disk_name: Display values for a specific disk.
disk.disk_utilization	The disk utilization percentage. This metric is available as of EEP 3.0.	<ul style="list-style-type: none"> disk_name: Display values for a specific disk.
disk.pending_operations	The number of pending disk operations.	<ul style="list-style-type: none"> disk_name: Display values for a specific disk.

Drill Metrics

Every 10 seconds, the collectd service uses the plugin to gather the following Drill metrics on each node in the cluster.

Name	Description
mapr.drill allocator_root_used	The amount of memory used in bytes by the internal memory allocator.
mapr.drill allocator_root_peak	The peak amount of memory used in bytes by the internal memory allocator.
mapr.drill blocked_count	The number of threads that are blocked because they are waiting for a monitor lock.
mapr.drill count	The number of live threads (including both daemon and non-daemon threads).
mapr.drill fd_usage	The ratio of used to total file descriptors.
mapr.drill fragments_running	The number of query fragments currently running in the drillbit.
mapr.drill heap_used	The amount of heap memory used in bytes by the JVM.

Name	Description
mapr.drill.non_heap_used	The amount of non-heap memory used in bytes by the JVM.
mapr.drill.queries_completed	The number of completed, canceled or failed queries for which this drillbit is the foreman.
mapr.drill.queries_running	The number of running queries for which this drillbit is the foreman.
mapr.drill.runnable_count	The number of threads executing in the JVM.
mapr.drill.waiting_count	The number of threads that are waiting to be executed. This can occur when a thread must wait for another thread to perform an action before proceeding.

Hive JMX Metrics

Every 10 seconds, the collectd service uses the Hive plug-in to gather the following Hive JMX metrics on each node in the cluster. Descriptions for the Hive metrics are not currently available.

Metric Collection

Metrics collected in Hive relate specifically to the HiveServer2 and Hive metastore processes. Each process runs in a separate JVM, and the JVMs provide values for the metrics.

Starting in EEP 6.3.2 and EEP 7.0.1, the `hive.exec.submit.local.task.via.child` option is set to `true` by default unless it is specified otherwise in `hive-site.xml` and enables HiveServer2 to spawn local tasks (typically mapjoin hashtable generation phase) in child JVMs. The system does not collect metrics for the child JVMs. The system only collects metrics for the HiveServer2 and Hive metastore processes.

Hive Metastore Metrics

The following are the JMX metrics provided for the Hive metastore:

- `mapr.hivemetastore.hivemetastore_buffers_direct_capacity`
- `mapr.hivemetastore.hivemetastore_buffers_direct_count`
- `mapr.hivemetastore.hivemetastore_buffers_direct_used`
- `mapr.hivemetastore.hivemetastore_buffers_mapped_capacity`
- `mapr.hivemetastore.hivemetastore_buffers_mapped_count`
- `mapr.hivemetastore.hivemetastore_buffers_mapped_used`
- `mapr.hivemetastore.hivemetastore_class_loading_loaded`
- `mapr.hivemetastore.hivemetastore_class_loading_unloaded`
- `mapr.hivemetastore.hivemetastore_gc_ps_mark_sweep_count`
- `mapr.hivemetastore.hivemetastore_gc_ps_mark_sweep_time`
- `mapr.hivemetastore.hivemetastore_gc_ps_scavenge_count`
- `mapr.hivemetastore.hivemetastore_gc_ps_scavenge_time`
- `mapr.hivemetastore.hivemetastore_init_total_count_dbs`
- `mapr.hivemetastore.hivemetastore_init_total_count_partitions`

- mapr.hivemetastore.hivemetastore_init_total_count_tables
- mapr.hivemetastore.hivemetastore_memory_heap_committed
- mapr.hivemetastore.hivemetastore_memory_heap_init
- mapr.hivemetastore.hivemetastore_memory_heap_max
- mapr.hivemetastore.hivemetastore_memory_heap_usage
- mapr.hivemetastore.hivemetastore_memory_heap_used
- mapr.hivemetastore.hivemetastore_memory_non_heap_committed
- mapr.hivemetastore.hivemetastore_memory_non_heap_init
- mapr.hivemetastore.hivemetastore_memory_non_heap_max
- mapr.hivemetastore.hivemetastore_memory_non_heap_usage
- mapr.hivemetastore.hivemetastore_memory_non_heap_used
- mapr.hivemetastore.hivemetastore_memory_pools_code_cache_usage
- mapr.hivemetastore.hivemetastore_memory_pools_compressed_class_space_usage
- mapr.hivemetastore.hivemetastore_memory_pools metaspace_usage
- mapr.hivemetastore.hivemetastore_memory_pools_ps eden_space_usage
- mapr.hivemetastore.hivemetastore_memory_pools_ps_old_gen_usage
- mapr.hivemetastore.hivemetastore_memory_pools_ps_survivor_space_usage
- mapr.hivemetastore.hivemetastore_memory_total_committed
- mapr.hivemetastore.hivemetastore_memory_total_init
- mapr.hivemetastore.hivemetastore_memory_total_max
- mapr.hivemetastore.hivemetastore_memory_total_used
- mapr.hivemetastore.hivemetastore_threads_blocked_count
- mapr.hivemetastore.hivemetastore_threads_count
- mapr.hivemetastore.hivemetastore_threads_daemon_count
- mapr.hivemetastore.hivemetastore_threads_deadlock_count
- mapr.hivemetastore.hivemetastore_threads_deadlocks
- mapr.hivemetastore.hivemetastore_threads_new_count

HiveServer2 Metrics

The following are the JMX metrics provided for HiveServer2 (hs2):

- `mapr.hiveserver2.hiveserver2_buffers_direct_capacity`
- `mapr.hiveserver2.hiveserver2_buffers_direct_count`
- `mapr.hiveserver2.hiveserver2_buffers_direct_used`
- `mapr.hiveserver2.hiveserver2_buffers_mapped_capacity`
- `mapr.hiveserver2.hiveserver2_buffers_mapped_count`
- `mapr.hiveserver2.hiveserver2_buffers_mapped_used`
- `mapr.hiveserver2.hiveserver2_class_loading_loaded`
- `mapr.hiveserver2.hiveserver2_class_loading_unloaded`
- `mapr.hiveserver2.hiveserver2_exec_async_pool_size`
- `mapr.hiveserver2.hiveserver2_exec_async_queue_size`
- `mapr.hiveserver2.hiveserver2_gc_ps_mark_sweep_count`
- `mapr.hiveserver2.hiveserver2_gc_ps_mark_sweep_time`
- `mapr.hiveserver2.hiveserver2_gc_ps_scavenge_count`
- `mapr.hiveserver2.hiveserver2_gc_ps_scavenge_time`
- `mapr.hiveserver2.hiveserver2_active_sessions`
- `mapr.hiveserver2.hiveserver2_open_sessions`
- `mapr.hiveserver2.hiveserver2_init_total_count_dbs`
- `mapr.hiveserver2.hiveserver2_init_total_count_partitions`
- `mapr.hiveserver2.hiveserver2_init_total_count_tables`
- `mapr.hiveserver2.hiveserver2_memory_heap_committed`
- `mapr.hiveserver2.hiveserver2_memory_heap_init`
- `mapr.hiveserver2.hiveserver2_memory_heap_max`
- `mapr.hiveserver2.hiveserver2_memory_heap_usage`

- `mapr.hiveserver2.hiveserver2_memory_heap_used`
- `mapr.hiveserver2.hiveserver2_memory_non_heap_committed`
- `mapr.hiveserver2.hiveserver2_memory_non_heap_init`
- `mapr.hiveserver2.hiveserver2_memory_non_heap_max`
- `mapr.hiveserver2.hiveserver2_memory_non_heap_usage`
- `mapr.hiveserver2.hiveserver2_memory_non_heap_used`
- `mapr.hiveserver2.hiveserver2_memory_pools_code_cache_usage`
- `mapr.hiveserver2.hiveserver2_memory_pools_compressed_class_space_usage`
- `mapr.hiveserver2.hiveserver2_memory_pools metaspace_usage`
- `mapr.hiveserver2.hiveserver2_memory_pools_ps eden_space_usage`
- `mapr.hiveserver2.hiveserver2_memory_pools_ps_old_gen_usage`
- `mapr.hiveserver2.hiveserver2_memory_pools_ps_survivor_space_usage`
- `mapr.hiveserver2.hiveserver2_memory_total_committed`
- `mapr.hiveserver2.hiveserver2_memory_total_init`
- `mapr.hiveserver2.hiveserver2_memory_total_max`
- `mapr.hiveserver2.hiveserver2_memory_total_used`
- `mapr.hiveserver2.hiveserver2_threads_blocked_count`
- `mapr.hiveserver2.hiveserver2_threads_count`
- `mapr.hiveserver2.hiveserver2_threads_daemon_count`
- `mapr.hiveserver2.hiveserver2_threads_deadlock_count`
- `mapr.hiveserver2.hiveserver2_threads_deadlocks`
- `mapr.hiveserver2.hiveserver2_threads_new_count`
- `mapr.hiveserver2.hiveserver2_threads_runnable_count`
- `mapr.hiveserver2.hiveserver2_threads_terminated_count`
- `mapr.hiveserver2.hiveserver2_threads_timed_waiting_count`
- `mapr.hiveserver2.hiveserver2_threads_waiting_count`
- `mapr.hiveserver2.hiveserver2_active_calls_api_get_all_databases`
- `mapr.hiveserver2.hiveserver2_active_calls_api_get_all_functions`
- `mapr.hiveserver2.hiveserver2_active_calls_api_get_all_tables`
- `mapr.hiveserver2.hiveserver2_active_calls_api_get_database`
- `mapr.hiveserver2.hiveserver2_active_calls_api_get_multi_table`

- `mapr.hiveserver2.hiveserver2_active_calls_api_get_table_objects_by_name_req`
- `mapr.hiveserver2.hiveserver2_active_calls_api_init`
- `mapr.hiveserver2.hiveserver2_jvm_pause_extra_sleep_time`
- `mapr.hiveserver2.hiveserver2_open_connections`
- `mapr.hiveserver2.hiveserver2_api_get_all_databases_count`
- `mapr.hiveserver2.hiveserver2_api_get_all_databases_max`
- `mapr.hiveserver2.hiveserver2_api_get_all_databases_mean`
- `mapr.hiveserver2.hiveserver2_api_get_all_databases_min`
- `mapr.hiveserver2.hiveserver2_api_get_all_databases_p50`

Kafka JMX Metrics

Starting in EEP 9.0.0, you can enable metrics collection for Kafka consumers and producers. When enabled, JMX collects Kafka producer and consumer metrics from client applications. You can view the metrics through the JConsole UI or JMXTerm CLI.

Metrics Collected

When you enable Kafka JMX metrics, you can view the following producer and consumer metrics through the JConsole UI or JMXTerm CLI :

Producer Metrics Collected

Global metrics collected:

- `record-send-rate`
- `record-send-total`
- `record-error-rate`
- `record-error-total`
- `record-size-max`
- `record-size-avg`

NOTE: Record size is computed as the sum of topic length, key size, value size, and sizes of keys and values of all headers if any exist.

Per-topic metrics collected:

- `record-send-rate`
- `record-send-total`
- `byte-rate`
- `byte-total`
- `record-error-rate`
- `record-error-total`

Consumer Metrics Collected

- `fetch-size-avg`
- `fetch-size-max`
- `bytes-consumed-rate`
- `bytes-consumed-total`
- `records-consumed-rate`
- `records-consumed-total`

NOTE: This list of supported metrics is a subset of all the Kafka JMX metrics. The unsupported metrics are either not registered or have default values such as 0 or NaN. A full list of Kafka JMX metrics is available [here](#).

Enabling Metrics Collection

To enable metrics collection, set `metrics.enabled=true` in the producer and consumer configuration.

The following sections provide steps to enable metrics collection and view metrics in the JConsole UI and JMXTerm CLI.

Using the JConsole UI to View Metrics

Complete the following steps to enable metrics collection and view metrics in the JConsole UI:

1. Start the console producer with metrics collection enabled:

```
bin/kafka-console-producer.sh --topic /s:t --producer-property  
metrics.enabled=true
```

2. Enter and send data.

3. In another terminal, run the following command to start JConsole:

```
jconsole
```

4. In JConsole, select the console producer process and connect to it.

5. Select **Insecure Connection**.

6. In the MBeans section, look at `kafka.producer` or `kafka.producer` domain, and select the MBean of interest to view its attributes.

7. Click **Refresh** to update attribute values.

Using the JMXTerm CLI to View Metrics

JMXTerm is the CLI analog of JConsole. To download JMXTerm, go to <https://docs.cyclopsgroup.org/jmxterm>.

Complete the following steps to enable metrics collection and view metrics through the JMXTerm CLI:

View Producer Metrics

1. Start the console producer with metrics collection enabled:

```
bin/kafka-console-producer.sh --topic /s:t --producer-property  
metrics.enabled=true
```

2. Run the following command to start JMXTerm in interactive mode:

```
java -jar jmxterm-1.0.2-uber.jar
```

3. Run the `jvms` command to identify which process is running the Kafka console producer:

```
jvms

WARNING: An illegal reflective access operation has occurred
WARNING: Illegal reflective access by
org.cyclopsgroup.jmxterm.utils.WeakCastUtils$2 (file:/home/mapr/
jmxterm-1.0.2-uber.jar) to method
sun.tools.jconsole.LocalVirtualMachine.getAllVirtualMachines()
WARNING: Please consider reporting this to the maintainers of
org.cyclopsgroup.jmxterm.utils.WeakCastUtils$2
WARNING: Use --illegal-access=warn to enable warnings of further illegal
reflective access operations

4113      ( ) - com.mapr.admin.AdminApplication
18946     (m) - org.apache.hadoop.yarn.server.nodemanager.NodeManager
3045     (m) -
org.apache.hadoop.yarn.server.resourcemanager.ResourceManager
23286     ( ) - org.apache.zookeeper.server.quorum.QuorumPeerMain /opt/
mapr/zookeeper/zookeeper-3.5.6/conf/zoo.cfg
29545     (m) - com.mapr.fs.cldb.CLDB /opt/mapr/conf/cldb.conf
4090      ( ) - jmxterm-1.0.2-uber.jar
26491     ( ) - com.mapr.warden.WardenMain /opt/mapr/conf/warden.conf
13003     (m) - org.apache.hadoop.mapreduce.v2.hs.JobHistoryServer
2286     (m) -
kafka.tools.ConsoleProducer --topic /s:t --producer-property
metrics.enabled=true
```

NOTE: In this example, the process is 2286. On your system, the process number may differ. Use the process number provided by your system.

4. Run the `open` command with the process number to open the connection:

```
open 2286
```

5. Run the following command to set the domain to `kafka.producer`:

```
domain kafka.producer
```

6. Run the `beans` command to see the beans available in the `kafka.producer` domain:

```
beans

#domain = kafka.producer:
kafka.producer:client-id=console-producer,topic="/
s:t",type=producer-topic-metrics
kafka.producer:client-id=console-producer,type=kafka-metrics-count
kafka.producer:client-id=console-producer,type=producer-metricseans
```

7. Set the bean to `kafka.producer:client-id=console-producer,type=producer-metrics`:

```
bean kafka.producer:client-id=console-producer,type=producer-metrics
```

8. Run the following command to get all the metrics for the `kafka.producer:client-id=console-producer,type=producer-metrics` bean:

```
get *

#mbean = kafka.producer:client-id=console-producer,type=producer-metrics:
record-send-rate = 0.0;
record-retry-total = 0.0;
record-size-avg = NaN;
batch-split-total = 0.0;
record-queue-time-avg = NaN;
request-latency-avg = NaN;
record-error-total = 0.0;
batch-split-rate = 0.0;
record-error-rate = 0.0;
record-send-total = 3.0;
batch-size-max = NaN;
compression-rate-avg = NaN;
record-queue-time-max = NaN;
record-retry-rate = 0.0;
request-latency-max = NaN;
record-size-max = NaN;
batch-size-avg = NaN;
records-per-request-avg = NaN;
```

View Consumer Metrics

1. Start the console consumer with metrics collection enabled:

```
bin/kafka-console-consumer.sh --topic /s1:t1 --consumer-property
metrics.enabled=true --from-beginning
```

2. Run the following command to start JMXTerm in interactive mode:

```
java -jar jmxterm-1.0.2-uber.jar
```

- Run the `jvms` command to identify which process is running the Kafka console consumer:

```
jvms

WARNING: An illegal reflective access operation has occurred
WARNING: Illegal reflective access by
org.cyclopsgroup.jmxterm.utils.WeakCastUtils$2 (file:/root/
jmxterm-1.0.2-uber.jar) to method
sun.tools.jconsole.LocalVirtualMachine.getAllVirtualMachines()
WARNING: Please consider reporting this to the maintainers of
org.cyclopsgroup.jmxterm.utils.WeakCastUtils$2
WARNING: Use --illegal-access=warn to enable warnings of further illegal

```

- Run the `open` command with the process number to open the connection:

NOTE: In this example, the process is 1531018. On your system, the process number may differ. Use the process number provided by your system.

```
open 1531018
```

- Run the following command to set the domain to `kafka.consumer`:

```
domain kafka.consumer
```

- Run the `beans` command to see the beans available in the `kafka.consumer` domain:

```
#domain = kafka.consumer:

kafka.consumer:client-id=console-consumer,type=consumer-fetch-manager-met
rics
kafka.consumer:client-id=console-consumer,type=consumer-metrics
kafka.consumer:client-id=console-consumer,type=kafka-metrics-count
```

- Set the bean to `kafka.consumer:client-id=<clientid>,type=consumer-fetch-manager-metrics`:

```
bean
kafka.consumer:client-id=console-consumer,type=consumer-fetch-manager-met
rics
```

8. Run the following command to get all the metrics for the `kafka.consumer:client-id=consumer-console,type=consumer-fetch-manager-metrics` bean:

```
get *
```

```
#mbean =
kafka.consumer:client-id=console-consumer,type=consumer-fetch-manager-met
rics:
  bytes-consumed-rate = 0.0;
  fetch-latency-max = NaN;
  fetch-rate = 0.0;
  fetch-total = 0.0;
  fetch-throttle-time-max = NaN;
  fetch-size-max = NaN;
  records-consumed-total = 0.0;
  records-lead-min = NaN;
  bytes-consumed-total = 0.0;
  fetch-latency-avg = NaN;
```

Load Metrics

Every 10 seconds, the `collectd` service uses the load plugin to gather the following load metrics on each node in the cluster.

Name	Description
load.load.longterm	The number of tasks running on the node every 15 minutes.
load.load.midterm	The number of tasks running on the node every 10 minutes.
load.load.shortterm	The number of tasks running on the node every minute.

Alarm Metrics

Every 10 seconds, the `collectd` service uses a plugin to gather the cluster alarms.

Name	Description	Additional Tag(s)
mapr.alarms.alarm_raised	The number of alarms raised. The timestamp for each alarm is based on the time that Data Fabric raised the alarm, not the time when the <code>collectd</code> service gathered the alarm data.	<ul style="list-style-type: none"> <code>alarm_name</code>: Display values for a specified alarm name. <code>alarm_entity</code>: . Display values for a specified volume, node, user, or group.

Cache Metrics

Every 10 seconds, the `collectd` service uses a plugin to gather the following Data Fabric file system cache metrics on each node in the cluster.

Name	Description
mapr.cache.lookups_data	The number of cache lookups in the block cache.
mapr.cache.lookups_dir	The number of cache lookups in the table LRU cache. The table LRU is used for storing internal B-Tree leaf pages.
mapr.cache.lookups_inode	The number of cache lookups in the inode cache.
mapr.cache.lookups_largefile	The number of cache lookups in the large file LRU cache. The large file LRU is used for storing files with size greater than 64K and also HPE Data Fabric Database data pages.

Name	Description
mapr.cache.lookups_meta	The number of cache lookups on the meta LRU cache. The meta LRU is used for storing internal B-Tree pages.
mapr.cache.lookups_smallfile	The number of cache lookups on the small file LRU cache. This LRU is used for storing files with size less than 64K and also HPE Data Fabric Database index pages.
mapr.cache.lookups_table	The number of cache lookups in the table LRU cache. The table LRU is used for storing internal B-Tree leaf pages.
mapr.cache.misses_data	The number of cache misses in the block cache.
mapr.cache.misses_dir	The number of cache misses on the table LRU cache.
mapr.cache.misses_inode	The number of cache misses in the inode cache.
mapr.cache.misses_largefile	The number of cache misses on the large file LRU cache.
mapr.cache.misses_meta	The number of cache misses on the meta LRU cache.
mapr.cache.misses_smallfile	The number of cache misses on the small file LRU cache.
mapr.cache.misses_table	The number of cache misses on the table LRU cache.

CLDB Metrics

Every 10 seconds, the collectd service uses a HPE Data Fabric plugin to gather the following CLDB metrics on the primary CLDB node in the cluster.

Name	Description
mapr.cldb.cluster_cpu_total	The number of physical CPUs in the cluster.
mapr.cldb.cluster_cpubusy_percent	The aggregate percentage of busy CPUs in the cluster.
mapr.cldb.cluster_disk_capacity	The storage capacity for HPE Data Fabric disks in GB.
mapr.cldb.cluster_diskspace_used	The amount of HPE Data Fabric disks used in GB.
mapr.cldb.cluster_memory_capacity	The memory capacity in MB.
mapr.cldb.cluster_memory_used	The amount of used memory in MB.
mapr.cldb.containers	The number of containers currently in the cluster.
mapr.cldb.containers_created	The cumulative number of containers created in the cluster. This value includes containers that have been deleted.
mapr.cldb.containers_unusable	The number of containers that are no longer usable. The CLDB marks a container as unusable when the node that stores the container is offline for 1 hour or more.
mapr.cldb.disk_space_available	The amount of disk space available in GB.
mapr.cldb.nodes_in_cluster	The number of nodes in the cluster.
mapr.cldb.fileserver_nodes_in-cluster	The number of nodes in the cluster that are currently running the mfs service.
mapr.cldb.nodes_offline	The number of nodes in the cluster that are offline.
mapr.cldb.rpc_received	The number of RPCs received.
mapr.cldb.rpcs_failed	The number of RPCs failed.
mapr.cldb.storage_pools_cluster	The number of storage pools.

Name	Description
mapr.cldb.storage_pools_offline	The number of offline storage pools.
mapr.cldb.volumes	The number of volumes created, including system volumes.

HPE Data Fabric Database Metrics

Every 10 seconds, the collectd service uses a plugin to gather HPE Data Fabric Database metrics on each node in the cluster. HPE Data Fabric Database provides both node and table metrics.

Node metrics capture data for operations across a MapR node. You can use them to assess the performance of individual nodes in your MapR cluster.

Starting in MapR 6.1, HPE Data Fabric Database supports table metrics. Table metrics provide more granular metrics. They allow you detect and diagnose bottlenecks and performance issues that are specific to individual tables. For example, suppose a node metric shows a spike in a particular RPC. Knowing this, you can use the corresponding table metric to determine if the spike originates from a single table.

Examples of other use cases that benefit from table metrics are the following:

- You want to measure the latency of different RPC operations on a table
- You want to determine which operations on a table are slow
- You want to determine which tables are most frequently accessed

HPE Data Fabric Database Node Metrics

This section describes the available HPE Data Fabric Database node metrics.

The following table lists HPE Data Fabric Database node metrics:

Metric Category	Name	Description
Throughput - RPC counts	mapr.db.append_rpcs	The number of HPE Data Fabric Database append RPCs completed
	mapr.db.checkandput_rpcs ¹	The number of HPE Data Fabric Database check and put RPCs completed
	mapr.db.get_currpcs	The number of HPE Data Fabric Database get RPCs in progress
	mapr.db.get_rpcrows	The number of get rows completed. Each get RPC can include multiple get rows.
	mapr.db.get_rpcs	The number of HPE Data Fabric Database get RPCs completed
	mapr.db.increment_rpcs ¹	The number of HPE Data Fabric Database increment RPCs completed
	mapr.db.put_currpcs	The number of HPE Data Fabric Database put RPCs in progress
	mapr.db.put_rpcs	The number of HPE Data Fabric Database put RPCs completed
	mapr.db.scan_currpcs	The number of HPE Data Fabric Database scan RPCs in progress
	mapr.db.scan_rpcrows	The number of scan rows completed. Each scan RPC can include multiple scan rows.
	mapr.db.scan_rpcs	The number of HPE Data Fabric Database scan RPCs completed
	mapr.db.updateandget_rpcs	The number of HPE Data Fabric Database update and get RPCs completed
Throughput - Row count written	mapr.db.append_rpcrows ¹	The number of rows written by append RPCs
	mapr.db.checkandput_rpcrows ¹	The number of rows written by check and put RPCs
	mapr.db.increment_rpcrows ¹	The number of rows written by increment RPCs
	mapr.db.put_rpcrows	The number of rows written by put RPCs. Each HPE Data Fabric Database put RPC can include multiple put rows.
	mapr.db.updateandget_rpcrows ¹	The number of rows written by update and get RPCs
Throughput - Rows returned	mapr.db.get_resprows ¹	The number of rows returned from get RPCs
	mapr.db.scan_resprows ¹	The number of rows returned from scan RPCs
Throughput - Row count read	mapr.db.get_readrows ¹	The number of rows read by get RPCs
	mapr.db.put_readrows ¹	The number of rows read by put RPCs
	mapr.db.scan_readrows ¹	The number of rows read by scan RPCs

Metric Category	Name	Description
Throughput - Bytes written	mapr.db.append_bytes ¹	The number of bytes written by append RPCs
	mapr.db.checkandput_bytes ¹	The number of bytes written by check and put RPCs
	mapr.db.put_bytes	The number of bytes written by put RPCs
	mapr.db.increment_bytes ¹	The number of bytes written by increment RPCs
	mapr.db.updateandget_bytes ¹	The number of bytes written by update and get RPCs
Throughput - Bytes read	mapr.db.get_bytes ¹	The number of bytes read by get RPCs
	mapr.db.scan_bytes ¹	The number of bytes read by scan RPCs
Value cache usage	mapr.db.valuecache_hits	The number of HPE Data Fabric Database operations that utilized the HPE Data Fabric Database value cache
	mapr.db.valuecache_lookups	The number of HPE Data Fabric Database operations that performed a lookup on the HPE Data Fabric Database value cache
	mapr.db.valuecache_usedSize	The HPE Data Fabric Database value cache size in MB
Compactions	mapr.db.fullcompacts ¹	<p>The number of compactions that combine multiple HPE Data Fabric Database data files containing sorted data (known as spills) into a single spill file.</p> <p>HPE Data Fabric Database creates a spill file each time it flushes files containing unsorted data (known as buckets). Full compactions improve read performance because after compaction, HPE Data Fabric Database needs to read only the single resulting sorted spill file. But they incur I/O costs because the compaction must read, sort, and rewrite all data in the spill files.</p>
	mapr.db.minicompacts ¹	<p>The number of compactions that combine multiple small data files containing sorted data (known as spills) into a single spill file.</p> <p>HPE Data Fabric Database creates a spill file each time it flushes files containing unsorted data (known as buckets). After a mini compaction, HPE Data Fabric Database needs to read only two spill files.</p>
	mapr.db.ttlcompacts ¹	<p>The number of compactions that result in reclamation of disk space due to removal of stale data.</p> <p>You can configure the TTL for a table if it has only a default column family. See table cf edit on page 2785 for details.</p>

Metric Category	Name	Description
Table flushes	<code>mapr.db.flushes</code> ¹	The number of flushes that reorganize data from bucket files (unsorted data) to spill files (sorted data) when the bucket size exceeds a threshold
	<code>mapr.db.forceflushes</code> ¹	The number of flushes that reorganize data from bucket files (unsorted data) to spill files (sorted data) when the in-memory bucket file cache fills up
CDC - Data sent	<code>mapr.db.cdc.sent_bytes</code> ¹	The number of bytes of CDC data sent
	<code>mapr.db.cdc.sent_rows</code> ¹	The number of rows of CDC data sent
Secondary indexes - Data sent	<code>mapr.db.index.sent_bytes</code> ¹	The number of bytes sent for secondary index updates
	<code>mapr.db.index.sent_rows</code> ¹	The number of rows sent for secondary index updates
Replication - Data sent	<code>mapr.db.repl.sent_bytes</code> ¹	The number of bytes sent to replicate data
	<code>mapr.db.repl.sent_rows</code> ¹	The number of rows sent to replicate data
CDC - Data pending	<code>mapr.db.cdc.pending_bytes</code> ¹	The number of bytes of CDC data remaining to be sent
	<code>mapr.db.cdc.pending_rows</code> ¹	The number of rows of CDC data remaining to be sent
Secondary indexes - Data pending	<code>mapr.db.index.pending_bytes</code> ¹	The number of bytes of secondary index data remaining to be sent
	<code>mapr.db.index.pending_rows</code> ¹	The number of rows of secondary index data remaining to be sent
Replication - Data pending	<code>mapr.db.repl.pending_bytes</code> ¹	The number of bytes of replication data remaining to be sent
	<code>mapr.db.repl.pending_rows</code> ¹	The number of rows of replication data remaining to be sent

¹ Available starting in MapR 6.1

HPE Data Fabric Database Table Metrics

Starting in 6.1, HPE Data Fabric Database supports table metrics. This section describes the available HPE Data Fabric Database table metrics. It also describes how to configure metrics per table, disable them in your cluster, and how to filter them by operation and table.

Table metrics are collected per node. By default, these metrics are written to OpenTSDB every minute. Pre-existing tables in your HPE Data Fabric cluster inherit this default setting. You can change this default per table using either the [table create](#) on page 2753 or [table edit](#) on page 2808 command. Secondary indexes inherit their metric configuration from their parent table.

You cannot disable metrics on individual tables. During installation, you can disable table metrics across your entire cluster. If you are using the installer, select the minimum metrics collection configuration option.

The following table lists HPE Data Fabric Database table metrics:

`mapr.db.table.latency`

The latency of RPC operations on tables, represented as a histogram. Endpoints identify histogram bucket boundaries.

NOTE: Put latency metrics for indexes reflect only the index update time. They do not include lag time due to [asynchronous index updates](#).

mapr.db.table.read_bytes	The number of bytes read from tables.
mapr.db.table.read_rows	The number of rows read from tables.
mapr.db.table.resp_rows	The number of rows returned from tables.
mapr.db.table.rpcs	The number of RPC calls completed on tables.
mapr.db.table.value_cache_hits	The number of HPE Data Fabric Database operations on tables that utilized the HPE Data Fabric Database value cache.
mapr.db.table.value_cache_lookups	The number of HPE Data Fabric Database operations on tables that performed a lookup on the HPE Data Fabric Database value cache.
mapr.db.table.write_rows	The number of rows written to tables.
mapr.db.table.write_bytes	The number of bytes written to tables.

Tags for Table Metrics

Each table metric collects data across all operations on tables and secondary indexes in a HPE Data Fabric node. To view metrics for a particular RPC operation on a specific table, you must filter the metric by RPC type and table path, as described in the following list:

rpc_type	<p>The name of the RPC:</p> <ul style="list-style-type: none"> • append • check_and_put • get • increment • put • scan • update_and_get
table_path	<p>The path of the HPE Data Fabric Database table. OpenTSDB supports only the following characters:</p> <ul style="list-style-type: none"> • Alphanumeric characters • Dot (.) • Underscore (_) • Dash (-) • Slash (/) • Space () • Unicode letters <p>If a table path contains characters that are not in this list, HPE Data Fabric cannot collect those table metrics.</p>

index

The name of the secondary index defined on the table specified in `table_path`, if you want to filter on a specific index. When you specify this tag, you cannot specify the `noindex` tag.

NOTE: You can use regular expressions when specifying the index name to filter for a group of indexes.

noindex

Set to `//primary` if you want to filter metrics for only the primary table and exclude metrics for secondary indexes defined on the table. When you specify this tag, you cannot specify the `index` tag.

The following list shows examples of the table-specific tags to use to filter different table metrics:

mapr.db.table.write_rows

Tag Name: `table_path`

Tag Value: `/var/mapr/mapr.monitoring/tsdb-meta`

Description: The number of rows written to a table in the path `/var/mapr/mapr.monitoring/tsdb-meta`, including writes to its secondary indexes.

mapr.db.table.rpcs

- • *Tag Name:* `rpc_type`
- *Tag Value:* `get`
- • *Tag Name:* `table_path`
- *Tag Value:* `/var/mapr/mapr.monitoring/tsdb-meta`
- • *Tag Name:* `noindex`
- *Tag Value:* `//primary`

Description: The number of completed `get` RPCs for a table in the path `/var/mapr/mapr.monitoring/tsdb-meta`, excluding metrics on the table's secondary indexes.

mapr.db.table.read_rows

- • *Tag Name:* `table_path`
- *Tag Value:* `/var/mapr/mapr.monitoring/tsdb-meta`
- • *Tag Name:* `index`
- *Tag Value:* `tsdbIdx`

Description: The number of rows read from a secondary index named `tsdbIdx`, defined on the table in the path `/var/mapr/mapr.monitoring/tsdb-meta`.

NOTE: In addition to these table-specific tags, [Metric Collection](#) on page 1963 describes other available tags.

HPE Data Fabric Streams Metrics

Every 10 seconds, the `collectd` service uses a plugin to gather the following Streams metrics on each node in the cluster.

Table

Name	Description
mapr.streams.produce_rpcs	The number of Streams producer RPCs. This metric is available as of EEP 2.0.
mapr.streams.produce_msgs	The number of Streams messages produced. This metric is available as of EEP 2.0.
mapr.streams.produce_bytes	The number of megabytes produced by Streams messages. This metric is available as of EEP 2.0.
mapr.streams.listen_rpcs	The number of Streams consumer RPCs. This metric is available as of EEP 2.0.
mapr.streams.listen_msgs	The number of Streams messages read by the consumer. This metric is available as of EEP 4.0.  NOTE: If you upgrade to EEP 4.0, all Streams messages are consumed, however this metric only reports a count on messages that were produced in EEP 4.0. Messages produced prior to EEP 4.0 are consumed, but not counted. In this scenario, the metric reports a partial count or a zero count if all messages were produced prior to EEP 4.0.
mapr.streams.listen_currpcs	The number of concurrent Stream consumer RPCs. This metric is available as of EEP 2.0.
mapr.streams.listen_bytes	The number of megabytes consumed by Streams messages. This metric is available as of EEP 2.0.

HPE Data Fabric Streams Telemetry Metrics

This section describes the available HPE Data Fabric Streams telemetry metrics.

Starting with HPE Data Fabric Release 7.10, HPE Data Fabric Streams supports telemetry metrics. Telemetry data can be collected and analyzed to gain insights into system performance. You can monitor and analyze streams performance in real-time to prevent potential performance bottle necks and suboptimal resource utilization. With detailed insights of specific topics/partitions and streams, you can detect anomalies and promptly resolve issues.

Every 10 seconds, the collectd service uses a plugin to gather the Streams Telemetry metrics on the cluster, node, streams and topic-partition level.

Streams telemetry is integrated with the Spyglass metrics workflow. See [Spyglass on Streams](#) on page 1962. The Streams telemetry metrics can be queried by a visualization tool, for example Grafana.

NOTE: Integration with Open Telemetry is planned for a future release. At that time an export plugin will be added.

The following table lists HPE Data Fabric Streams telemetry metrics:

Metric Type	Name	Description
Producer Metrics - Topic-partition level ¹	mapr.stream.producer.nfputs	The number of failed puts.
	mapr.stream.producer.nputs	The number of put requests.
	mapr.stream.producer.nrecs	The number of records.
	mapr.stream.producer.psize_avg	The average put size.
	mapr.stream.producer.psize_max	The maximum put size.
	mapr.stream.producer.psize_min	The minimum put size.
	mapr.stream.producer.psize_tot	The put size total.
	mapr.stream.producer.ravgsz	The average record size.
Producer Metrics - Node level	mapr.stream.producer.ibytes	In bytes.
	mapr.stream.producer.iotime_avg	The average wait time in reading the put request data from the socket.
	mapr.stream.iotime_max	The maximum wait time in reading the put request data from the socket.
	mapr.stream.iotime_min	The minimum wait time in reading the put request data from the socket.
	mapr.stream.producer.latency_avg	The average latency of put requests.
	mapr.stream.producer.latency_max	The maximum latency of put requests.
	mapr.stream.producer.latency_min	The minimum latency of put requests.
	mapr.stream.producer.nbatches	The number of batches in the put request.
	mapr.stream.producer.nfreqs	The number of failed put requests.
	mapr.stream.producer.nreqs	The number of put requests.
Consumer Metrics - Topic-Partition level ¹	mapr.stream.consumer.nfetches	The number of fetches.
	mapr.stream.consumer.nrecs	The number of records.
	mapr.stream.consumer.ravgsz	The average record size.
	mapr.stream.consumer.fsize_avg	The average fetch size.
	mapr.stream.consumer.fsize_max	The maximum fetch size.
	mapr.stream.consumer.fsize_min	The minimum fetch size.
	mapr.stream.consumer.fsize_tot	The fetch size total.

Metric Type	Name	Description
Consumer Metrics - Node level	mapr.stream.consumer.obytes	Out bytes.
	mapr.stream.consumer.iotime_avg	The average time to write the data to the socket.
	mapr.stream.consumer.iotime_max	The maximum time to write the data to the socket.
	mapr.stream.consumer.iotime_min	The minimum time to write the data to the socket.
	mapr.stream.consumer.latency_avg	The average latency of fetch requests.
	mapr.stream.consumer.latency_max	The maximum latency of fetch requests.
	mapr.stream.consumer.latency_min	The minimum latency of fetch requests.
	mapr.stream.consumer.nfresps	The number of fetches.
	mapr.stream.consumer.nresps	The number of responses.

¹ Contains the following tags:

- hostname
- stream_fid
- producer_id
- topic_name
- partition_id

NOTE: In Release 7.10, producer_id and partition_id are not added as tags.

Enabling Metrics Collection

To enable metrics collection, set the configuration value for `mfs.enable.streams.metrics`.

```
maprcli config save -values {"mfs.enable.streams.metrics":"1"} -json
```

file system Metrics

Every 10 seconds, the collectd service uses a HPE Data Fabric plugin to gather the following file system metrics on each node in the cluster.

Name	Description
mapr.fs.bulk_writes	The number of bulk-write operations. Bulk-write operations occur when the primary file system container aggregates multiple small file writes from one or more clients into one big RPC, before replicating the writes.
mapr.fs.bulk_writesbytes	The amount of MB written by bulk-write operations. Bulk-write operations occur when the primary file system container aggregates multiple small file writes from one or more clients into one big RPC, before replicating the writes.
