/**@}*/

/**
* @name Transactional producer API
*
* The transactional producer operates on top of the idempotent producer,
* and provides full exactly-once semantics (EOS) for Apache Kafka when used
* with the transaction aware consumer (\c isolation.level=read_committed).
*
* A producer instance is configured for transactions by setting the
* \c transactional.id to an identifier unique for the application. This
* id will be used to fence stale transactions from previous instances of
* the application, typically following an outage or crash.
*
* After creating the transactional producer instance using rd_kafka_new()
* the transactional state must be initialized by calling
* rd_kafka_init_transactions(). This is a blocking call that will
* acquire a runtime producer id from the transaction coordinator broker
* as well as abort any stale transactions and fence any still running
producer
* instances with the same \c transactional.id.
*
* Once transactions are initialized the application may begin a new
* transaction by calling rd_kafka_begin_transaction().
* A producer instance may only have one single on-going transaction.
*
* Any messages produced after the transaction has been started will
* belong to the ongoing transaction and will be committed or aborted
* atomically.
* It is not permitted to produce messages outside a transaction
* boundary, e.g., before rd_kafka_begin_transaction() or after
* rd_kafka_commit_transaction(), rd_kafka_abort_transaction(), or after
* the current transaction has failed.
*
* If consumed messages are used as input to the transaction, the consumer
* instance must be configured with \c enable.auto.commit set to \c false.
* To commit the consumed offsets along with the transaction pass the
* list of consumed partitions and the last offset processed + 1 to
* rd_kafka_send_offsets_to_transaction() prior to committing the
transaction.
* This allows an aborted transaction to be restarted using the previously
* committed offsets.
*

```

```

* To commit the produced messages, and any consumed offsets, to the
* current transaction, call rd_kafka_commit_transaction().
* This call will block until the transaction has been fully committed or
* failed (typically due to fencing by a newer producer instance).
*
* Alternatively, if processing fails, or an abortable transaction error is
* raised, the transaction needs to be aborted by calling
* rd_kafka_abort_transaction() which marks any produced messages and
* offset commits as aborted.
*
* After the current transaction has been committed or aborted a new
* transaction may be started by calling rd_kafka_begin_transaction() again.
*
* @par Retriable errors
* Some error cases allow the attempted operation to be retried, this is
* indicated by the error object having the retrieable flag set which can
* be detected by calling rd_kafka_error_is_retriable().
* When this flag is set the application may retry the operation immediately
* or preferably after a shorter grace period (to avoid busy-looping).
* Retriable errors include timeouts, broker transport failures, etc.
*
* @par Abortable errors
* An ongoing transaction may fail permanently due to various errors,
* such as transaction coordinator becoming unavailable, write failures to
the
* Apache Kafka log, under-replicated partitions, etc.
* At this point the producer application must abort the current transaction
* using rd_kafka_abort_transaction() and optionally start a new transaction
* by calling rd_kafka_begin_transaction().
* Whether an error is abortable or not is detected by calling
* rd_kafka_error_txn_requires_abort() on the returned error object.
*
* @par Fatal errors
* While the underlying idempotent producer will typically only raise
* fatal errors for unrecoverable cluster errors where the idempotency
* guarantees can't be maintained, most of these are treated as abortable by
* the transactional producer since transactions may be aborted and retried
* in their entirety;
* The transactional producer on the other hand introduces a set of
additional
* fatal errors which the application needs to handle by shutting down the
* producer and terminate. There is no way for a producer instance to
recover
* from fatal errors.
* Whether an error is fatal or not is detected by calling
* rd_kafka_error_is_fatal() on the returned error object or by checking
* the global rd_kafka_fatal_error() code.
* Fatal errors are raised by triggering the \c error_cb (see the
* Fatal error chapter in INTRODUCTION.md for more information), and any
* subsequent transactional API calls will return RD_KAFKA_RESP_ERR_FATAL
* or have the fatal flag set (see rd_kafka_error_is_fatal()).
* The originating fatal error code can be retrieved by calling
* rd_kafka_fatal_error().
*
* @par Handling of other errors
* For errors that have neither retrieable, abortable or the fatal flag set
* it is not always obvious how to handle them. While some of these errors
* may be indicative of bugs in the application code, such as when
* an invalid parameter is passed to a method, other errors might originate
* from the broker and be passed thru as-is to the application.
* The general recommendation is to treat these errors, that have
* neither the retrieable or abortable flags set, as fatal.
*
* @par Error handling example

```

```

* @code
*     retry:
*         rd_kafka_error_t *error;
*
*         error = rd_kafka_commit_transaction(producer, 10*1000);
*         if (!error)
*             return success;
*         else if (rd_kafka_error_txn_requires_abort(error)) {
*             do_abort_transaction_and_reset_inputs();
*         } else if (rd_kafka_error_is_retriable(error)) {
*             rd_kafka_error_destroy(error);
*             goto retry;
*         } else { // treat all other errors as fatal errors
*             fatal_error(rd_kafka_error_string(error));
*         }
*         rd_kafka_error_destroy(error);
* @endcode
*
*
* @{}
*/

/**
* @brief Initialize transactions for the producer instance.
*
* This function ensures any transactions initiated by previous instances
* of the producer with the same \c transactional.id are completed.
* If the previous instance failed with a transaction in progress the
* previous transaction will be aborted.
* This function needs to be called before any other transactional or
* produce functions are called when the \c transactional.id is configured.
*
* If the last transaction had begun completion (following transaction
commit)
* but not yet finished, this function will await the previous transaction's
* completion.
*
* When any previous transactions have been fenced this function
* will acquire the internal producer id and epoch, used in all future
* transactional messages issued by this producer instance.
*
* @param rk Producer instance.
* @param timeout_ms The maximum time to block. On timeout the operation
* may continue in the background, depending on state,
* and it is okay to call init_transactions() again.
* If an infinite timeout (-1) is passed, the timeout will
* be adjusted to 2 * \c transaction.timeout.ms.
*
* @remark This function may block up to \p timeout_ms milliseconds.
*
* @remark This call is resumable when a retrieable timeout error is
returned.
*     Calling the function again will resume the operation that is
*     progressing in the background.
*
* @returns NULL on success or an error object on failure.
*     Check whether the returned error object permits retrying
*     by calling rd_kafka_error_is_retriable(), or whether a fatal
*     error has been raised by calling rd_kafka_error_is_fatal().
*     Error codes:
*     RD_KAFKA_RESP_ERR_TIMED_OUT if the transaction coordinator
*     could be not be contacted within \p timeout_ms (retriable),
*     RD_KAFKA_RESP_ERR_COORDINATOR_NOT_AVAILABLE if the transaction

```

```

*      coordinator is not available (retriable),
*      RD_KAFKA_RESP_ERR_CONCURRENT_TRANSACTIONS if a previous
transaction
*      would not complete within \p timeout_ms (retriable),
*      RD_KAFKA_RESP_ERR__STATE if transactions have already been
started
*      or upon fatal error,
*      RD_KAFKA_RESP_ERR__UNSUPPORTED_FEATURE if the broker(s) do not
*      support transactions (<Apache Kafka 0.11), this also raises a
*      fatal error,
*      RD_KAFKA_RESP_ERR_INVALID_TRANSACTION_TIMEOUT if the configured
*      \c transaction.timeout.ms is outside the broker-configured
range,
*      this also raises a fatal error,

* avoid timing out the transaction on the broker:
*   * rd_kafka_produce() (et.al)
*   * rd_kafka_send_offsets_to_transaction()
*   * rd_kafka_commit_transaction()
*   * rd_kafka_abort_transaction()
*
* Any messages produced, offsets sent
(rd_kafka_send_offsets_to_transaction()),
* etc, after the successful return of this function will be part of
* the transaction and committed or aborted automatically.
*
* Finish the transaction by calling rd_kafka_commit_transaction() or
* abort the transaction by calling rd_kafka_abort_transaction().
*
* @param rk Producer instance.
*
* @returns NULL on success or an error object on failure.
* Check whether a fatal error has been raised by
* calling rd_kafka_error_is_fatal().
* Error codes:
*   RD_KAFKA_RESP_ERR__STATE if a transaction is already in progress
*   or upon fatal error,
*   RD_KAFKA_RESP_ERR__NOT_CONFIGURED if transactions have not been
*   configured for the producer instance,

```

```

*      RD_KAFKA_RESP_ERR__INVALID_ARG if \p rk is not a producer
instance.
*      Other error codes not listed here may be returned, depending on
*      broker version.
*
* @remark With the transactional producer, rd_kafka_produce(),
* rd_kafka_producev(), et.al, are only allowed during an on-going
* transaction, as started with this function.
* Any produce call outside an on-going transaction, or for a failed
* transaction, will fail.
*
* @remark The returned error object (if not NULL) must be destroyed with
* rd_kafka_error_destroy().
*/
RD_EXPORT
rd_kafka_error_t *rd_kafka_begin_transaction(rd_kafka_t *rk);

/**
* @brief Sends a list of topic partition offsets to the consumer group
* coordinator for \p cgmetadata, and marks the offsets as part
* part of the current transaction.
* These offsets will be considered committed only if the
transaction is
* committed successfully.
*
* The offsets should be the next message your application will
consume,
* i.e., the last processed message's offset + 1 for each partition.
* Either track the offsets manually during processing or use
* rd_kafka_position() (on the consumer) to get the current offsets
for
* the partitions assigned to the consumer.
*
* Use this method at the end of a consume-transform-produce loop
prior
* to committing the transaction with rd_kafka_commit_transaction().
*
* @param rk Producer instance.
* @param offsets List of offsets to commit to the consumer group upon
* successful commit of the transaction. Offsets should be
* the next message to consume, e.g., last processed message
+ 1.
* @param cgmetadata The current consumer group metadata as returned by
* rd_kafka_consumer_group_metadata() on the consumer
* instance the provided offsets were consumed from.
* @param timeout_ms Maximum time allowed to register the offsets on the
broker.
*
* @remark This function must be called on the transactional producer
instance,
* not the consumer.
*
* @remark The consumer must disable auto commits
* (set \c enable.auto.commit to false on the consumer).
*
* @remark Logical and invalid offsets (such as RD_KAFKA_OFFSET_INVALID) in
* \p offsets will be ignored, if there are no valid offsets in
* \p offsets the function will return NULL and no action will be
taken.
*
* @remark This call is retrievable but not resumable, which means a new
request
* with a new set of provided offsets and group metadata will be

```

```

*         sent to the transaction coordinator if the call is retried.
*
* @remark It is highly recommended to retry the call (upon retrieable error)
*         with identical \p offsets and \p cgmetadata parameters.
*         Failure to do so risks inconsistent state between what is
actually
*         included in the transaction and what the application thinks is
*         included in the transaction.
*
* @returns NULL on success or an error object on failure.
*         Check whether the returned error object permits retrying
*         by calling rd_kafka_error_is_retriable(), or whether an
abortable
*         or fatal error has been raised by calling
*         rd_kafka_error_txn_requires_abort() or rd_kafka_error_is_fatal()
*         respectively.
*         Error codes:
*         RD_KAFKA_RESP_ERR__STATE if not currently in a transaction,
*         RD_KAFKA_RESP_ERR__INVALID_PRODUCER_EPOCH if the current producer
*         transaction has been fenced by a newer producer instance,
*         RD_KAFKA_RESP_ERR__TRANSACTIONAL_ID_AUTHORIZATION_FAILED if the
*         producer is no longer authorized to perform transactional
*         operations,
*         RD_KAFKA_RESP_ERR__GROUP_AUTHORIZATION_FAILED if the producer is
*         not authorized to write the consumer offsets to the group
*         coordinator,
*         RD_KAFKA_RESP_ERR__NOT_CONFIGURED if transactions have not been
*         configured for the producer instance,
*         RD_KAFKA_RESP_ERR__INVALID_ARG if \p rk is not a producer
instance,
*         or if the \p consumer_group_id or \p offsets are empty.
*         Other error codes not listed here may be returned, depending on
*         broker version.
*
* @remark The returned error object (if not NULL) must be destroyed with
*         rd_kafka_error_destroy().
*/
RD_EXPORT

    rd_kafka_t *rk,
    const rd_kafka_topic_partition_list_t *offsets,
    const rd_kafka_consumer_group_metadata_t *cgmetadata,
    int timeout_ms);

/**
* @brief Commit the current transaction (as started with
*         rd_kafka_begin_transaction()).
*
*         Any outstanding messages will be flushed (delivered) before
actually
*         committing the transaction.
*
*         If any of the outstanding messages fail permanently the current
*         transaction will enter the abortable error state and this
*         function will return an abortable error, in this case the
application
*         must call rd_kafka_abort_transaction() before attempting a new
*         transaction with rd_kafka_begin_transaction().
*
* @param rk Producer instance.
* @param timeout_ms The maximum time to block. On timeout the operation
*         may continue in the background, depending on state,
*         and it is okay to call this function again.

```

```

*           Pass -1 to use the remaining transaction timeout,
*           this is the recommended use.
*
* @remark It is strongly recommended to always pass -1 (remaining
transaction
*           time) as the \p timeout_ms. Using other values risk internal
*           state desynchronization in case any of the underlying protocol
*           requests fail.
*
* @remark This function will block until all outstanding messages are
*           delivered and the transaction commit request has been
successfully
*           handled by the transaction coordinator, or until \p timeout_ms
*           expires, whichever comes first. On timeout the application may
*           call the function again.
*
* @remark Will automatically call rd_kafka_flush() to ensure all queued
*           messages are delivered before attempting to commit the
*           transaction.
*           If the application has enabled RD_KAFKA_EVENT_DR it must
*           serve the event queue in a separate thread since rd_kafka_flush()
*           will not serve delivery reports in this mode.
*
* @remark This call is resumable when a retrievable timeout error is
returned.
*           Calling the function again will resume the operation that is
*           progressing in the background.
*
* @returns NULL on success or an error object on failure.
*           Check whether the returned error object permits retrying
*           by calling rd_kafka_error_is_retriable(), or whether an
abortable
*           or fatal error has been raised by calling
*           rd_kafka_error_txn_requires_abort() or rd_kafka_error_is_fatal()
*           respectively.
*           Error codes:

librdkafka 2.0.2

Apache librdkafka 2.0.2 is supported as of HPE Data Fabric 7.9.0/EEP 9.3.1.

IMPORTANT: As of release 6.0.1, the RD_KAFKA_MSG_F_BLOCK call provides *blocking* behavior, whereas, the RD_KAFKA_MSG_F_COPY and RD_KAFKA_MSG_F_FREE calls are *non-blocking*.

 * @brief Generic event callback to be used with the event API to trigger
 *        callbacks for \c rd_kafka_event_t objects from a background
 *        thread serving the background queue.
 *
 * How to use:
 * 1. First set the event callback on the configuration object with this
 *    function, followed by creating an rd_kafka_t instance
 *    with rd_kafka_new().
 * 2. Get the instance's background queue with
rd_kafka_queue_get_background()
 *    and pass it as the reply/response queue to an API that takes an
 *    event queue, such as rd_kafka_CreateTopics().
 * 3. As the response event is ready and enqueued on the background queue
the
 *    event callback will be triggered from the background thread.
 * 4. Prior to destroying the client instance, loose your reference to the
 *    background queue by calling rd_kafka_queue_destroy().
 *
 * The application must destroy the \c rkev passed to \p event cb using
 * rd_kafka_event_destroy().
 *
 * The \p event_cb \c opaque argument is the opaque set with
 * rd_kafka_conf_set_opaque().
 *
 * @remark This callback is a specialized alternative to the poll-based
 *        event API described in the Event interface section.
 *
 * @remark The \p event_cb will be called spontaneously from a background
 *        thread completely managed by librdkafka.
 *        Take care to perform proper locking of application objects.
 *
 * @warning The application MUST NOT call rd_kafka_destroy() from the
 *        event callback.
 *

 *
 * The \p consume_cb \p opaque argument is the opaque set with
 * rd_kafka_conf_set_opaque().
 */
RD_EXPORT
void rd_kafka_conf_set_consume_cb(
    rd_kafka_conf_t *conf,
    void (*consume_cb)(rd_kafka_message_t *rkmessage, void *opaque));

/**
 * @brief \b Consumer: Set rebalance callback for use with
 *         coordinated consumer group balancing.
 *
 * The \p err field is set to either RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS
 * or RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS and 'partitions'
 * contains the full partition set that was either assigned or revoked.
 *
 * Registering a \p rebalance_cb turns off librdkafka's automatic
 * partition assignment/revocation and instead delegates that responsibility
 * to the application's \p rebalance_cb.
 *
 * The rebalance callback is responsible for updating librdkafka's
 * assignment set based on the two events:
RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS
* and RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS but should also be able to
handle
* arbitrary rebalancing failures where \p err is neither of those.

```

```

* @remark In this latter case (arbitrary error), the application must
*         call rd_kafka_assign(rk, NULL) to synchronize state.
*
* For eager/non-cooperative `partition.assignment.strategy` assignors,
* such as `range` and `roundrobin`, the application must use
* rd_kafka_assign() to set or clear the entire assignment.
* For the cooperative assignors, such as `cooperative-sticky`, the
application
* must use rd_kafka_incremental_assign() for
* RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS and rd_kafka_incremental_unassign()
* for RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS.
*
* Without a rebalance callback this is done automatically by librdkafka
* but registering a rebalance callback gives the application flexibility
* in performing other operations along with the assigning/revocation,
* such as fetching offsets from an alternate location (on assign)
* or manually committing offsets (on revoke).
*
* rebalance_cb is always triggered exactly once when a rebalance completes
* with a new assignment, even if that assignment is empty. If an
* eager/non-cooperative assignor is configured, there will eventually be
* exactly one corresponding call to rebalance_cb to revoke these partitions
* (even if empty), whether this is due to a group rebalance or lost
* partitions. In the cooperative case, rebalance_cb will never be called if
* the set of partitions being revoked is empty (whether or not lost).
*
* The callback's \p opaque argument is the opaque set with
rd_kafka_conf_set_opaque().
*
* @remark The \p partitions list is destroyed by librdkafka on return
*         return from the rebalance_cb and must not be freed or
*         saved by the application.
*
* @remark Be careful when modifying the \p partitions list.
*         Changing this list should only be done to change the initial
*         offsets for each partition.
*         But a function like `rd_kafka_position()` might have unexpected
*         effects for instance when a consumer gets assigned a partition
*         it used to consume at an earlier rebalance. In this case, the
*         list of partitions will be updated with the old offset for that
*         partition. In this case, it is generally better to pass a copy
*         of the list (see `rd_kafka_topic_partition_list_copy()`).
*         The result of `rd_kafka_position()` is typically outdated in
RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS.
*
* @sa rd_kafka_assign()
* @sa rd_kafka_incremental_assign()
* @sa rd_kafka_incremental_unassign()
* @sa rd_kafka_assignment_lost()
* @sa rd_kafka_rebalance_protocol()
*
* The following example shows the application's responsibilities:
* @code
static void rebalance_cb (rd_kafka_t *rk, rd_kafka_resp_err_t err,
                        rd_kafka_topic_partition_list_t *partitions,
                        void *opaque) {
*
*     switch (err)
*     {
*     case RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS:
*         // application may load offsets from arbitrary external
*         // storage here and update \p partitions
*         if (!strcmp(rd_kafka_rebalance_protocol(rk), "COOPERATIVE"))
rd_kafka_incremental_assign(rk, partitions);
*

```

```

*         else // EAGER
*             rd_kafka_assign(rk, partitions);
*         break;
*
*     case RD_KAFKA_RESP_ERR_REVOKE_PARTITIONS:
*         if (manual_commits) // Optional explicit manual commit
*             rd_kafka_commit(rk, partitions, 0); // sync commit
*
*         if (!strcmp(rd_kafka_rebalance_protocol(rk), "COOPERATIVE"))
*             rd_kafka_incremental_unassign(rk, partitions);
*         else // EAGER
*             rd_kafka_assign(rk, NULL);
*         break;
*
*     default:
*         handle_unlikely_error(err);
*         rd_kafka_assign(rk, NULL); // sync state
*         break;
*     }
* }
* @endcode
*
* @remark The above example lacks error handling for assign calls, see
*         the examples/ directory.

/**
* @brief Set SASL/OAUTHBEARER token refresh callback in provided conf
object.
*
* @param conf the configuration to mutate.
* @param oauthbearer_token_refresh_cb the callback to set; callback
function
* arguments:<br>
* \p rk - Kafka handle<br>
* \p oauthbearer_config - Value of configuration property
*                       sasl.oauthbearer.config.
* \p opaque - Application-provided opaque set via

```

```

*          rd_kafka_conf_set_opaque()
*
* The SASL/OAUTHBEARER token refresh callback is triggered via
rd_kafka_poll()
* whenever OAUTHBEARER is the SASL mechanism and a token needs to be
retrieved,
* typically based on the configuration defined in \c
sasl.oauthbearer.config.
*
* The callback should invoke rd_kafka_oauthbearer_set_token()
* or rd_kafka_oauthbearer_set_token_failure() to indicate success
* or failure, respectively.
*
* The refresh operation is eventable and may be received via
* rd_kafka_queue_poll() with an event type of
* \c RD_KAFKA_EVENT_OAUTHBEARER_TOKEN_REFRESH.
*
* Note that before any SASL/OAUTHBEARER broker connection can succeed the
* application must call rd_kafka_oauthbearer_set_token() once -- either
* directly or, more typically, by invoking either rd_kafka_poll(),
* rd_kafka_consumer_poll(), rd_kafka_queue_poll(), etc, in order to cause
* retrieval of an initial token to occur.
*
* Alternatively, the application can enable the SASL queue by calling
* rd_kafka_conf_enable_sasl_queue() on the configuration object prior to
* creating the client instance, get the SASL queue with
* rd_kafka_queue_get_sasl(), and either serve the queue manually by calling
* rd_kafka_queue_poll(), or redirecting the queue to the background thread
to
* have the queue served automatically. For the latter case the SASL queue
* must be forwarded to the background queue with rd_kafka_queue_forward().
* A convenience function is available to automatically forward the SASL
queue
* to librdkafka's background thread, see
* rd_kafka_sasl_background_callbacks_enable().
*
* An unsecured JWT refresh handler is provided by librdkafka for
development
* and testing purposes, it is enabled by setting
* the \c enable.sasl.oauthbearer.unsecure.jwt property to true and is
* mutually exclusive to using a refresh callback.
*
* @sa rd_kafka_sasl_background_callbacks_enable()
* @sa rd_kafka_queue_get_sasl()
*/

```

```

*
*
*/

/**
 * @brief Subscribe to topic set using balanced consumer groups.
 *
 * Wildcard (regex) topics are supported:
 * any topic name in the \p topics list that is prefixed with \c "\" will
 * be regex-matched to the full list of topics in the cluster and matching
 * topics will be added to the subscription list.
 *
 * The full topic list is retrieved every \c
topic.metadata.refresh.interval.ms
 * to pick up new or delete topics that match the subscription.
 * If there is any change to the matched topics the consumer will
 * immediately rejoin the group with the updated set of subscribed topics.
 *
 * Regex and full topic names can be mixed in \p topics.
 *
 * @remark Only the \c .topic field is used in the supplied \p topics list,
 * all other fields are ignored.
 *
 * @remark subscribe() is an asynchronous method which returns immediately:
 * background threads will (re)join the group, wait for group
rebalance,
 * issue any registered rebalance_cb, assign() the assigned
partitions,
 * and then start fetching messages. This cycle may take up to
 * \c session.timeout.ms * 2 or more to complete.
 *
 * @remark After this call returns a consumer error will be returned by
 * rd_kafka_consumer_poll (et.al) for each unavailable topic in the
 * \p topics. The error will be
RD_KAFKA_RESP_ERR_UNKNOWN_TOPIC_OR_PART
 * for non-existent topics, and

```

```

queue.
result      *          Failure to do so will
on          *          in indefinitely blocking
the         *          the produce() call when
            *          message queue is full. */
#define
RD_KAFKA_MSG_F_PARTITION 0x8 /**< produce_batch() will
honor          * per-message partition. */

/**
 * @brief Produce and send a single message to broker.
 *
 * \p rkt is the target topic which must have been previously created with
 * `rd_kafka_topic_new()`.
 *
 * `rd_kafka_produce()` is an asynchronous non-blocking API.
 * See `rd_kafka_conf_set_dr_msg_cb` on how to setup a callback to be called
 * once the delivery status (success or failure) is known. The delivery
report
 * is triggered by the application calling `rd_kafka_poll()` (at regular
 * intervals) or `rd_kafka_flush()` (at termination).
 *
 * Since producing is asynchronous, you should call `rd_kafka_flush()`
before
 * you destroy the producer. Otherwise, any outstanding messages will be
 * silently discarded.
 *
 * When temporary errors occur, librdkafka automatically retries to produce
the
 * messages. Retries are triggered after retry.backoff.ms and when the
 * leader broker for the given partition is available. Otherwise, librdkafka
 * falls back to polling the topic metadata to monitor when a new leader is
 * elected (see the topic.metadata.refresh.fast.interval.ms and
 * topic.metadata.refresh.interval.ms configurations) and then performs a
 * retry. A delivery error will occur if the message could not be produced
 * within message.timeout.ms.
 *
 * See the "Message reliability" chapter in INTRODUCTION.md for more
 * information.
 *
 * \p partition is the target partition, either:
 *   - RD_KAFKA_PARTITION_UA (unassigned) for
 *     automatic partitioning using the topic's partitioner function, or
 *   - a fixed partition (0..N)
 *
 * \p msgflags is zero or more of the following flags OR'ed together:
 *   RD_KAFKA_MSG_F_BLOCK - block \p produce*() call if
 *                         \p queue.buffering.max.messages or
 *                         \p queue.buffering.max.kbytes are exceeded.
 *                         Messages are considered in-queue from the point
 * they are accepted by produce() until their corresponding delivery report
 * callback/event returns. It is thus a requirement to call rd_kafka_poll()
(or
 * equiv.) from a separate thread when F_BLOCK is used. See WARNING on \c
 * RD_KAFKA_MSG_F_BLOCK above.
 *
 * RD_KAFKA_MSG_F_FREE - rdkafka will free(3) \p payload when it is done

```

```

*                                     with it.
*   RD_KAFKA_MSG_F_COPY - the \p payload data will be copied and the
*                          \p payload pointer will not be used by rdkafka
*                          after the call returns.
*   RD_KAFKA_MSG_F_PARTITION - produce_batch() will honour per-message
*                              partition, either set manually or by the
*                              configured partitioner.
*
*   .._F_FREE and .._F_COPY are mutually exclusive. If neither of these
are
*   set, the caller must ensure that the memory backing \p payload remains
*   valid and is not modified or reused until the delivery callback is
*   invoked. Other buffers passed to `rd_kafka_produce()` don't have this
*   restriction on reuse, i.e. the memory backing the key or the topic
name
*   may be reused as soon as `rd_kafka_produce()` returns.
*
*   If the function returns -1 and RD_KAFKA_MSG_F_FREE was specified, then
*   the memory associated with the payload is still the caller's
*   responsibility.
*
*   \p payload is the message payload of size \p len bytes.
*
*   \p key is an optional message key of size \p keylen bytes, if non-NULL it
*   will be passed to the topic partitioner as well as be sent with the
*   message to the broker and passed on to the consumer.
*
*   \p msg_opaque is an optional application-provided per-message opaque
*   pointer that will be provided in the message's delivery report callback
*   (\c dr_msg_cb or \c dr_cb) and the \c rd_kafka_message_t \c _private
field.
*
*   @remark on_send() and on_acknowledgement() interceptors may be called
*           from this function. on_acknowledgement() will only be called if
the
*           message fails partitioning.
*
*   @remark If the producer is transactional (\c transactional.id is
configured)
*           producing is only allowed during an on-going transaction, namely
*           after rd_kafka_begin_transaction() has been called.
*
*   @returns 0 on success or -1 on error in which case errno is set
accordingly:
*   - ENOBUFS - maximum number of outstanding messages has been reached:
*               "queue.buffering.max.messages"
*               (RD_KAFKA_RESP_ERR__QUEUE_FULL)
*   - EMSGSIZE - message is larger than configured max size:
*               "messages.max.bytes".
*               (RD_KAFKA_RESP_ERR_MSG_SIZE_TOO_LARGE)
*   - ESRCH - requested \p partition is unknown in the Kafka cluster.
*             (RD_KAFKA_RESP_ERR__UNKNOWN_PARTITION)
*   - ENOENT - topic is unknown in the Kafka cluster.
*             (RD_KAFKA_RESP_ERR__UNKNOWN_TOPIC)
*   - ECANCELED - fatal error has been raised on producer, see
*                 rd_kafka_fatal_error(),
*                 (RD_KAFKA_RESP_ERR__FATAL).
*   - ENOEXEC - transactional state forbids producing
*               (RD_KAFKA_RESP_ERR__STATE)
*
*   @sa Use rd_kafka_errno2err() to convert `errno` to rdkafka error code.
*/

                                         * on mapr streams
                                         */
};

/**
 * @brief List and describe client groups in cluster.
 *
 * \p group is an optional group name to describe, otherwise (\c NULL) all
 * groups are returned.
 *
 * \p timeout_ms is the (approximate) maximum time to wait for response
 * from brokers and must be a positive value.
 *
 * @returns \c RD_KAFKA_RESP_ERR_NO_ERROR on success and \p grplistp is
 *          updated to point to a newly allocated list of groups.
 *          \c RD_KAFKA_RESP_ERR_PARTIAL if not all brokers responded
 *          in time but at least one group is returned in \p grplistp.
 *          \c RD_KAFKA_RESP_ERR_TIMED_OUT if no groups were returned in
the
 *          given timeframe but not all brokers have yet responded, or
 *          if the list of brokers in the cluster could not be obtained
within
 *          the given timeframe.
 *          \c RD_KAFKA_RESP_ERR_TRANSPORT if no brokers were found.
 *          Other error codes may also be returned from the request layer.
 *
 *          The \p grplistp remains untouched if any error code is
returned,
 *          with the exception of RD_KAFKA_RESP_ERR_PARTIAL which behaves
 *          as RD_KAFKA_RESP_ERR_NO_ERROR (success) but with an incomplete
 *          group list.
 *
 * @sa Use rd_kafka_group_list_destroy() to release list memory.
 *
 * @deprecated Use rd_kafka_ListConsumerGroups() and
 *              rd_kafka_DescribeConsumerGroups() instead.

/**
* @name Miscellaneous APIs
* @{
*
*
*
* @brief Adds one or more brokers to the kafka handle's list of initial
bootstrap brokers.
*
* Additional brokers will be discovered automatically as soon as rdkafka
connects to a broker by querying the broker metadata.
*
* If a broker name resolves to multiple addresses (and possibly
address families) all will be used for connection attempts in
round-robin fashion.
*
* \p brokerlist is a , -separated list of brokers in the format:
* \c \<broker1\>,\<broker2\>,...
* Where each broker is in either the host or URL based format:
* \c \<host\>[:\<port\>]
* \c \<proto\>://\<host\>[:port]
* \c \<proto\> is either \c PLAINTEXT, \c SSL, \c SASL, \c SASL_PLAINTEXT
* The two formats can be mixed but ultimately the value of the
`security.protocol` config property decides what brokers are allowed.
*
* Example:
* brokerlist = "broker1:10000,broker2"
* brokerlist = "SSL://broker3:9000,ssl://broker2"
*
* @returns the number of brokers successfully added.
*
* @remark Brokers may also be defined with the \c metadata.broker.list or
\c bootstrap.servers configuration property (preferred method).
*
* @deprecated Set bootstrap servers with the \c bootstrap.servers
configuration property.

/**
 * @name Interceptors
 *
 * @{
 *
 * @brief A callback interface that allows message interception for both
 *        producer and consumer data pipelines.
 *
 * Except for the on_new(), on_conf_set(), on_conf_dup() and
on_conf_destroy()
 * interceptors, interceptors are added to the
 * newly created rd_kafka_t client instance. These interceptors MUST only
 * be added from on_new() and MUST NOT be added after rd_kafka_new()
returns.
 *
 * The on_new(), on_conf_set(), on_conf_dup() and on_conf_destroy()
interceptors
 * are added to the configuration object which is later passed to
 * rd_kafka_new() where on_new() is called to allow addition of
 * other interceptors.
 *
 * Each interceptor reference consists of a display name (ic_name),
 * a callback function, and an application-specified opaque value that is
 * passed as-is to the callback.
 * The ic_name must be unique for the interceptor implementation and is used
 * to reject duplicate interceptor methods.
 *
 * Any number of interceptors can be added and they are called in the order
 * they were added, unless otherwise noted.
 * The list of registered interceptor methods are referred to as
 * interceptor chains.
 *
 * @remark Contrary to the Java client the librdkafka interceptor interface
 *        does not support message key and value modification.
 *        Message mutability is discouraged in the Java client and the
 *        combination of serializers and headers cover most use-cases.
 *
 * @remark Interceptors are NOT copied to the new configuration on
 *        rd_kafka_conf_dup() since it would be hard for interceptors to
 *        track usage of the interceptor's opaque value.
 *        An interceptor should rely on the plugin, which will be copied
 *        in rd_kafka_conf_dup(), to set up the initial interceptors.
 *        An interceptor should implement the on_conf_dup() method
 *        to manually set up its internal configuration on the newly
created
 *        configuration object that is being copied-to based on the
 *        interceptor-specific configuration properties.
 *        conf_dup() should thus be treated the same as conf_init().
 *
 * @remark Interceptors are keyed by the interceptor type (on_..()), the
 *        interceptor name (ic_name) and the interceptor method function.

```

```

*      Duplicates are not allowed and the ..add_on..() method will
*      return RD_KAFKA_RESP_ERR_CONFLICT if attempting to add a
duplicate
*      method.
*      The only exception is on_conf_destroy() which may be added
multiple
*      times by the same interceptor to allow proper cleanup of
*      interceptor configuration state.
*/

/**
* @brief on_conf_set() is called from rd_kafka*_conf_set() in the order
*       the interceptors were added.
*
* @param conf Configuration object.

/**
* @name Admin API
* @{
*
* @brief The Admin API enables applications to perform administrative
* Apache Kafka tasks, such as creating and deleting topics,
* altering and reading broker configuration, etc.
*
* The Admin API is asynchronous and makes use of librdkafka's standard
* \c rd_kafka_queue_t queues to propagate the result of an admin operation
* back to the application.
* The supplied queue may be any queue, such as a temporary single-call
queue,
* a shared queue used for multiple requests, or even the main queue or
* consumer queues.
*
* Use \c rd_kafka_queue_poll() to collect the result of an admin operation
* from the queue of your choice, then extract the admin API-specific result
* type by using the corresponding \c rd_kafka_event_CreateTopics_result,

```

```

* \c rd_kafka_event_DescribeConfigs_result, etc, methods.
* Use the getter methods on the \c .._result_t type to extract response
* information and finally destroy the result and event by calling
* \c rd_kafka_event_destroy().
*
* Use rd_kafka_event_error() and rd_kafka_event_error_string() to acquire
* the request-level error/success for an Admin API request.
* Even if the returned value is \c RD_KAFKA_RESP_ERR_NO_ERROR there
* may be individual objects (topics, resources, etc) that have failed.
* Extract per-object error information with the corresponding
* \c rd_kafka_..._result_topics|resources|..() to check per-object errors.
*
* Locally triggered errors:
* - \c RD_KAFKA_RESP_ERR__TIMED_OUT - (Controller) broker connection did
not
* become available in the time allowed by
AdminOption_set_request_timeout.

/**@}*/

/**
 * @name Transactional producer API
 *
 * The transactional producer operates on top of the idempotent producer,
 * and provides full exactly-once semantics (EOS) for Apache Kafka when used
 * with the transaction aware consumer (\c isolation.level=read_committed).
 *
 * A producer instance is configured for transactions by setting the
 * \c transactional.id to an identifier unique for the application. This
 * id will be used to fence stale transactions from previous instances of
 * the application, typically following an outage or crash.
 *
 * After creating the transactional producer instance using rd_kafka_new()
 * the transactional state must be initialized by calling
 * rd_kafka_init_transactions(). This is a blocking call that will
 * acquire a runtime producer id from the transaction coordinator broker
 * as well as abort any stale transactions and fence any still running
producer
 * instances with the same \c transactional.id.
 *
 * Once transactions are initialized the application may begin a new
 * transaction by calling rd_kafka_begin_transaction().
 * A producer instance may only have one single on-going transaction.
 *
 * Any messages produced after the transaction has been started will
 * belong to the ongoing transaction and will be committed or aborted
 * atomically.
 * It is not permitted to produce messages outside a transaction
 * boundary, e.g., before rd_kafka_begin_transaction() or after
 * rd_kafka_commit_transaction(), rd_kafka_abort_transaction(), or after
 * the current transaction has failed.
 *
 * If consumed messages are used as input to the transaction, the consumer
 * instance must be configured with \c enable.auto.commit set to \c false.
 * To commit the consumed offsets along with the transaction pass the
 * list of consumed partitions and the last offset processed + 1 to
 * rd_kafka_send_offsets_to_transaction() prior to committing the
transaction.
 * This allows an aborted transaction to be restarted using the previously
 * committed offsets.
 *
 * To commit the produced messages, and any consumed offsets, to the
 * current transaction, call rd_kafka_commit_transaction().
 * This call will block until the transaction has been fully committed or
 * failed (typically due to fencing by a newer producer instance).
 *
 * Alternatively, if processing fails, or an abortable transaction error is
 * raised, the transaction needs to be aborted by calling
 * rd_kafka_abort_transaction() which marks any produced messages and
 * offset commits as aborted.
 *
 * After the current transaction has been committed or aborted a new
 * transaction may be started by calling rd_kafka_begin_transaction() again.
 *
 * @par Retriable errors
 * Some error cases allow the attempted operation to be retried, this is
 * indicated by the error object having the retrieable flag set which can

```

```

* be detected by calling rd_kafka_error_is_retriable().
* When this flag is set the application may retry the operation immediately
* or preferably after a shorter grace period (to avoid busy-looping).
* Retriable errors include timeouts, broker transport failures, etc.
*
* @par Abortable errors
* An ongoing transaction may fail permanently due to various errors,
* such as transaction coordinator becoming unavailable, write failures to
the
* Apache Kafka log, under-replicated partitions, etc.
* At this point the producer application must abort the current transaction
* using rd_kafka_abort_transaction() and optionally start a new transaction
* by calling rd_kafka_begin_transaction().
* Whether an error is abortable or not is detected by calling
* rd_kafka_error_txn_requires_abort() on the returned error object.
*
* @par Fatal errors
* While the underlying idempotent producer will typically only raise
* fatal errors for unrecoverable cluster errors where the idempotency
* guarantees can't be maintained, most of these are treated as abortable by
* the transactional producer since transactions may be aborted and retried
* in their entirety;
* The transactional producer on the other hand introduces a set of
additional
* fatal errors which the application needs to handle by shutting down the
* producer and terminate. There is no way for a producer instance to
recover
* from fatal errors.
* Whether an error is fatal or not is detected by calling
* rd_kafka_error_is_fatal() on the returned error object or by checking
* the global rd_kafka_fatal_error() code.
* Fatal errors are raised by triggering the \c error_cb (see the
* Fatal error chapter in INTRODUCTION.md for more information), and any
* subsequent transactional API calls will return RD_KAFKA_RESP_ERR_FATAL
* or have the fatal flag set (see rd_kafka_error_is_fatal()).
* The originating fatal error code can be retrieved by calling
* rd_kafka_fatal_error().
*
* @par Handling of other errors
* For errors that have neither retriable, abortable or the fatal flag set
* it is not always obvious how to handle them. While some of these errors
* may be indicative of bugs in the application code, such as when
* an invalid parameter is passed to a method, other errors might originate
* from the broker and be passed thru as-is to the application.
* The general recommendation is to treat these errors, that have
* neither the retriable or abortable flags set, as fatal.
*
* @par Error handling example
* @code
*     retry:
*         rd_kafka_error_t *error;
*
*         error = rd_kafka_commit_transaction(producer, 10*1000);
*         if (!error)
*             return success;
*         else if (rd_kafka_error_txn_requires_abort(error)) {
*             do_abort_transaction_and_reset_inputs();
*         } else if (rd_kafka_error_is_retriable(error)) {
*             rd_kafka_error_destroy(error);
*             goto retry;
*         } else { // treat all other errors as fatal errors
*             fatal_error(rd_kafka_error_string(error));
*         }
*         rd_kafka_error_destroy(error);

```

```

* @endcode
*
*

*/

/**
* @brief Initialize transactions for the producer instance.
*
* This function ensures any transactions initiated by previous instances
* of the producer with the same \c transactional.id are completed.
* If the previous instance failed with a transaction in progress the
* previous transaction will be aborted.
* This function needs to be called before any other transactional or
* produce functions are called when the \c transactional.id is configured.
*
* If the last transaction had begun completion (following transaction
commit)
* but not yet finished, this function will await the previous transaction's
* completion.
*
* When any previous transactions have been fenced this function
* will acquire the internal producer id and epoch, used in all future
* transactional messages issued by this producer instance.
*
* @param rk Producer instance.
* @param timeout_ms The maximum time to block. On timeout the operation
* may continue in the background, depending on state,
* and it is okay to call init_transactions() again.
* If an infinite timeout (-1) is passed, the timeout will
* be adjusted to 2 * \c transaction.timeout.ms.
*
* @remark This function may block up to \p timeout_ms milliseconds.
*
* @remark This call is resumable when a retrieable timeout error is
returned.
* Calling the function again will resume the operation that is
* progressing in the background.
*
* @returns NULL on success or an error object on failure.
* Check whether the returned error object permits retrying
* by calling rd_kafka_error_is_retriable(), or whether a fatal
* error has been raised by calling rd_kafka_error_is_fatal().
* Error codes:
* RD_KAFKA_RESP_ERR_TIMED_OUT if the transaction coordinator
* could be not be contacted within \p timeout_ms (retriable),
* RD_KAFKA_RESP_ERR_COORDINATOR_NOT_AVAILABLE if the transaction
* coordinator is not available (retriable),
* RD_KAFKA_RESP_ERR_CONCURRENT_TRANSACTIONS if a previous
transaction
* would not complete within \p timeout_ms (retriable),
* RD_KAFKA_RESP_ERR_STATE if transactions have already been
started
* or upon fatal error,
* RD_KAFKA_RESP_ERR_UNSUPPORTED_FEATURE if the broker(s) do not
* support transactions (<Apache Kafka 0.11), this also raises a
* fatal error,
* RD_KAFKA_RESP_ERR_INVALID_TRANSACTION_TIMEOUT if the configured
* \c transaction.timeout.ms is outside the broker-configured
range,
* this also raises a fatal error,
* RD_KAFKA_RESP_ERR_NOT_CONFIGURED if transactions have not been
* configured for the producer instance,

```

```

*      RD_KAFKA_RESP_ERR__INVALID_ARG if \p rk is not a producer
instance,
*      or \p timeout_ms is out of range.
*      Other error codes not listed here may be returned, depending on
*      broker version.
*
* @remark The returned error object (if not NULL) must be destroyed with
*      rd_kafka_error_destroy().
*/

RD_EXPORT
rd_kafka_error_t *rd_kafka_begin_transaction(rd_kafka_t *rk);

```

```

/**
 * @brief Sends a list of topic partition offsets to the consumer group
 *        coordinator for \p cgmetadata, and marks the offsets as part
 *        part of the current transaction.
 *        These offsets will be considered committed only if the
transaction is
 *        committed successfully.
 *
 *        The offsets should be the next message your application will
consume,
 *        i.e., the last processed message's offset + 1 for each partition.
 *        Either track the offsets manually during processing or use
 *        rd_kafka_position() (on the consumer) to get the current offsets
for
 *        the partitions assigned to the consumer.
 *
 *        Use this method at the end of a consume-transform-produce loop
prior
 *        to committing the transaction with rd_kafka_commit_transaction().
 *
 * @param rk Producer instance.
 * @param offsets List of offsets to commit to the consumer group upon
 *                successful commit of the transaction. Offsets should be
 *                the next message to consume, e.g., last processed message
+ 1.
 * @param cgmetadata The current consumer group metadata as returned by
 *                   rd_kafka_consumer_group_metadata() on the consumer
 *                   instance the provided offsets were consumed from.
 * @param timeout_ms Maximum time allowed to register the offsets on the
broker.
 *
 * @remark This function must be called on the transactional producer
instance,
 *        not the consumer.
 *
 * @remark The consumer must disable auto commits
 *        (set \c enable.auto.commit to false on the consumer).
 *
 * @remark Logical and invalid offsets (such as RD_KAFKA_OFFSET_INVALID) in
 *        \p offsets will be ignored, if there are no valid offsets in
 *        \p offsets the function will return NULL and no action will be
taken.
 *
 * @remark This call is retrievable but not resumable, which means a new
request
 *        with a new set of provided offsets and group metadata will be
 *        sent to the transaction coordinator if the call is retried.
 *
 * @remark It is highly recommended to retry the call (upon retrievable error)
 *        with identical \p offsets and \p cgmetadata parameters.
 *        Failure to do so risks inconsistent state between what is
actually
 *        included in the transaction and what the application thinks is
 *        included in the transaction.
 *
 * @returns NULL on success or an error object on failure.
 *        Check whether the returned error object permits retrying
 *        by calling rd_kafka_error_is_retriable(), or whether an
abortable
 *        or fatal error has been raised by calling
 *        rd_kafka_error_txn_requires_abort() or rd_kafka_error_is_fatal()
 *        respectively.

```

```

/**
* @brief Commit the current transaction (as started with
*      rd_kafka_begin_transaction()).
*
*      Any outstanding messages will be flushed (delivered) before
actually
*      committing the transaction.
*
*      If any of the outstanding messages fail permanently the current
*      transaction will enter the abortable error state and this
*      function will return an abortable error, in this case the
application
*      must call rd_kafka_abort_transaction() before attempting a new
*      transaction with rd_kafka_begin_transaction().
*
* @param rk Producer instance.
* @param timeout_ms The maximum time to block. On timeout the operation
*      may continue in the background, depending on state,
*      and it is okay to call this function again.
*      Pass -1 to use the remaining transaction timeout,
*      this is the recommended use.
*
* @remark It is strongly recommended to always pass -1 (remaining
transaction
*      time) as the \p timeout_ms. Using other values risk internal
*      state desynchronization in case any of the underlying protocol
*      requests fail.
*
* @remark This function will block until all outstanding messages are
*      delivered and the transaction commit request has been
successfully
*      handled by the transaction coordinator, or until \p timeout_ms
*      expires, which ever comes first. On timeout the application may
*      call the function again.
*

```

```

* @remark Will automatically call rd_kafka_flush() to ensure all queued
* messages are delivered before attempting to commit the
* transaction.
* If the application has enabled RD_KAFKA_EVENT_DR it must
* serve the event queue in a separate thread since rd_kafka_flush()
* will not serve delivery reports in this mode.
*
* @remark This call is resumable when a retrievable timeout error is
returned.
* Calling the function again will resume the operation that is
* progressing in the background.
*
* @returns NULL on success or an error object on failure.
* Check whether the returned error object permits retrying

librdkafka 0.11.3

Apache librdkafka 0.11.3 is supported as of HPE Data Fabric 6.0.1/EEP5.0.

IMPORTANT: With this release, the RD_KAFKA_MSG_F_BLOCK call provides *blocking* behavior, whereas, the RD_KAFKA_MSG_F_COPY and RD_KAFKA_MSG_F_FREE calls are *non-blocking* (this is a behavior change from previous releases).

/**
 * @brief \b Consumer: Set rebalance callback for use with
 * coordinated consumer group balancing.
 *
 * The \p err field is set to either RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS
 * or RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS and 'partitions'
 * contains the full partition set that was either assigned or revoked.
 *
 * Registering a \p rebalance_cb turns off librdkafka's automatic
 * partition assignment/revocation and instead delegates that responsibility
 * to the application's \p rebalance_cb.
 *
 * The rebalance callback is responsible for updating librdkafka's
 * assignment set based on the two events:
RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS
 * and RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS but should also be able to
handle
 * arbitrary rebalancing failures where \p err is neither of those.
 * @remark In this latter case (arbitrary error), the application must
 * call rd_kafka_assign(rk, NULL) to synchronize state.
 *
 * Without a rebalance callback this is done automatically by librdkafka
 * but registering a rebalance callback gives the application flexibility
 * in performing other operations along with the assinging/revocation,
 * such as fetching offsets from an alternate location (on assign)
 * or manually committing offsets (on revoke).
 *
 * @remark The \p partitions list is destroyed by librdkafka on return
 * return from the rebalance_cb and must not be freed or
 * saved by the application.
 *
 * The following example shows the application's responsibilities:
 * @code

```

```

* static void rebalance_cb (rd_kafka_t *rk, rd_kafka_resp_err_t err,
*                          rd_kafka_topic_partition_list_t *partitions,
*                          void *opaque) {
*
*     switch (err)
*     {
*     case RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS:
*         // application may load offsets from arbitrary external
*         // storage here and update \p partitions
*
*         rd_kafka_assign(rk, partitions);
*         break;
*
*     case RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS:
*         if (manual_commits) // Optional explicit manual commit
*             rd_kafka_commit(rk, partitions, 0); // sync commit
*
*         rd_kafka_assign(rk, NULL);
*         break;
*
*     default:
*         handle_unlikely_error(err);
*         rd_kafka_assign(rk, NULL); // sync state
*         break;
*     }
* }
* @endcode

 * `rd_kafka_produce()` is an asynch non-blocking API.
 *
 * \p partition is the target partition, either:
 * - RD_KAFKA_PARTITION_UA (unassigned) for
 *   automatic partitioning using the topic's partitioner function, or
 * - a fixed partition (0..N)
 *
 * \p msgflags is zero or more of the following flags OR'ed together:
 * RD_KAFKA_MSG_F_BLOCK - block \p produce*() call if
 * \p queue.buffering.max.messages or

```

```

*                                     \p queue.buffering.max.kbytes are exceeded.
*                                     Messages are considered in-queue from the
point they
*                                     are accepted by produce() until their
corresponding
*                                     delivery report callback/event returns.
*                                     It is thus a requirement to call
*                                     rd_kafka_poll() (or equiv.) from a separate
*                                     thread when F_BLOCK is used.
*                                     See WARNING on \c RD_KAFKA_MSG_F_BLOCK above.
*
* RD_KAFKA_MSG_F_FREE - rdkafka will free(3) \p payload when it is done
*                       with it.
* RD_KAFKA_MSG_F_COPY - the \p payload data will be copied and the
*                       \p payload pointer will not be used by rdkafka
*                       after the call returns.
*
* .._F_FREE and .._F_COPY are mutually exclusive.
*
* If the function returns -1 and RD_KAFKA_MSG_F_FREE was specified, then
* the memory associated with the payload is still the caller's
* responsibility.
*
* \p payload is the message payload of size \p len bytes.
*
* \p key is an optional message key of size \p keylen bytes, if non-NULL it
* will be passed to the topic partitioner as well as be sent with the
* message to the broker and passed on to the consumer.
*
* \p msg_opaque is an optional application-provided per-message opaque
* pointer that will be provided in the delivery report callback (`dr_cb`) for
* referencing this message.
*
* @remark on_send() and on_acknowledgement() interceptors may be called
*         from this function. on_acknowledgement() will only be called if
the
*         message fails partitioning.
*
* @returns 0 on success or -1 on error in which case errno is set
accordingly:
*   - ENOBUFS - maximum number of outstanding messages has been reached:
*               "queue.buffering.max.messages"
*               (RD_KAFKA_RESP_ERR__QUEUE_FULL)
*   - EMSGSIZE - message is larger than configured max size:
*               "messages.max.bytes".
*               (RD_KAFKA_RESP_ERR__MSG_SIZE_TOO_LARGE)
*   - ESRCH - requested \p partition is unknown in the Kafka cluster.
*             (RD_KAFKA_RESP_ERR__UNKNOWN_PARTITION)
*   - ENOENT - topic is unknown in the Kafka cluster.
*             (RD_KAFKA_RESP_ERR__UNKNOWN_TOPIC)
*
* @sa Use rd_kafka_errno2err() to convert `errno` to rdkafka error code.

/**
 * @name Miscellaneous APIs
 * @{
 *
 */

/**
 * @brief Adds one or more brokers to the kafka handle's list of initial
 *        bootstrap brokers.
 *
 * Additional brokers will be discovered automatically as soon as rdkafka
 * connects to a broker by querying the broker metadata.
 *
 * If a broker name resolves to multiple addresses (and possibly
 * address families) all will be used for connection attempts in
 * round-robin fashion.
 *
 * \p brokerlist is a , -separated list of brokers in the format:
 *   \c \<broker1\>,\<broker2\>,...
 * Where each broker is in either the host or URL based format:
 *   \c \<host\>[:\<port\>]
 *   \c \<proto\>://\<host\>[:port]
 * \c \<proto\> is either \c PLAINTEXT, \c SSL, \c SASL, \c SASL_PLAINTEXT
 * The two formats can be mixed but ultimately the value of the
 * `security.protocol` config property decides what brokers are allowed.
 *
 * Example:
 *   brokerlist = "broker1:10000,broker2"
 *   brokerlist = "SSL://broker3:9000,ssl://broker2"
 *
 * @returns the number of brokers successfully added.
 *
 * @remark Brokers may also be defined with the \c metadata.broker.list or
 *         \c bootstrap.servers configuration property (preferred method).

/**@}*/

/**
* @name Interceptors
*
* @{
*
* @brief A callback interface that allows message interception for both
*      producer and consumer data pipelines.
*
* Except for the on_new(), on_conf_set(), on_conf_dup() and
on_conf_destroy()
* interceptors, interceptors are added to the
* newly created rd_kafka_t client instance. These interceptors MUST only
* be added from on_new() and MUST NOT be added after rd_kafka_new()
returns.
*
* The on_new(), on_conf_set(), on_conf_dup() and on_conf_destroy()
interceptors
* are added to the configuration object which is later passed to
* rd_kafka_new() where on_new() is called to allow addition of
* other interceptors.
*
* Each interceptor reference consists of a display name (ic_name),
* a callback function, and an application-specified opaque value that is
* passed as-is to the callback.
* The ic_name must be unique for the interceptor implementation and is used
* to reject duplicate interceptor methods.
*
* Any number of interceptors can be added and they are called in the order
* they were added, unless otherwise noted.
* The list of registered interceptor methods are referred to as
* interceptor chains.
*
* @remark Contrary to the Java client the librdkafka interceptor interface
*      does not support message modification. Message mutability is
*      discouraged in the Java client and the combination of
*      serializers and headers cover most use-cases.
*
* @remark Interceptors are NOT copied to the new configuration on

```

```

*      rd_kafka_conf_dup() since it would be hard for interceptors to
*      track usage of the interceptor's opaque value.
*      An interceptor should rely on the plugin, which will be copied
*      in rd_kafka_conf_dup(), to set up the initial interceptors.
*      An interceptor should implement the on_conf_dup() method
*      to manually set up its internal configuration on the newly
created
*      configuration object that is being copied-to based on the
*      interceptor-specific configuration properties.
*      conf_dup() should thus be treated the same as conf_init().
*
* @remark Interceptors are keyed by the interceptor type (on_..()), the
*          interceptor name (ic_name) and the interceptor method function.
*          Duplicates are not allowed and the ..add_on_..() method will
*          return RD_KAFKA_RESP_ERR_CONFLICT if attempting to add a
duplicate
*          method.
*          The only exception is on_conf_destroy() which may be added
multiple
*          times by the same interceptor to allow proper cleanup of
*          interceptor configuration state.
*/

/**
* @brief on_conf_set() is called from rd_kafka_*_conf_set() in the order
*        the interceptors were added.
*
* @param ic_opaque The interceptor's opaque pointer specified in ..add_..().
* @param name The configuration property to set.
* @param val The configuration value to set, or NULL for reverting to
default
*        in which case the previous value should be freed.
* @param errstr A human readable error string in case the interceptor
fails.
* @param errstr_size Maximum space (including \0) in \p errstr.
*
* @returns RD_KAFKA_CONF_RES_OK if the property was known and successfully
*          handled by the interceptor, RD_KAFKA_CONF_RES_INVALID if the
*          property was handled by the interceptor but the value was
invalid,
*          or RD_KAFKA_CONF_RES_UNKNOWN if the interceptor did not handle
*          this property, in which case the property is passed on on the
*          interceptor in the chain, finally ending up at the built-in
*          configuration handler.

/**
 * @brief \b Consumer: Set rebalance callback for use with
 *
 * coordinated consumer group balancing.
 *
 * The \p err field is set to either RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS
 * or RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS and 'partitions'
 * contains the full partition set that was either assigned or revoked.
 */

```

```

* Registering a \p rebalance_cb turns off librdkafka's automatic
* partition assignment/revocation and instead delegates that responsibility
* to the application's \p rebalance_cb.
*
* The rebalance callback is responsible for updating librdkafka's
* assignment set based on the two events:
RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS
* and RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS but should also be able to
handle
* arbitrary rebalancing failures where \p err is neither of those.
* @remark In this latter case (arbitrary error), the application must
* call rd_kafka_assign(rk, NULL) to synchronize state.
*
* Without a rebalance callback this is done automatically by librdkafka
* but registering a rebalance callback gives the application flexibility
* in performing other operations along with the assigning/revocation,
* such as fetching offsets from an alternate location (on assign)
* or manually committing offsets (on revoke).
*
* @remark The \p partitions list is destroyed by librdkafka on return
* return from the rebalance_cb and must not be freed or
* saved by the application.
*
* The following example shows the application's responsibilities:
* @code
* static void rebalance_cb (rd_kafka_t *rk, rd_kafka_resp_err_t err,
*                          rd_kafka_topic_partition_list_t *partitions,
*                          void *opaque) {
*
*     switch (err)
*     {
*     case RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS:
*         // application may load offsets from arbitrary external
*         // storage here and update \p partitions
*
*         rd_kafka_assign(rk, partitions);
*         break;
*
*     case RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS:
*         if (manual_commits) // Optional explicit manual commit
*             rd_kafka_commit(rk, partitions, 0); // sync commit
*
*         rd_kafka_assign(rk, NULL);
*         break;
*
*     default:
*         handle_unlikely_error(err);
*         rd_kafka_assign(rk, NULL); // sync state
*         break;
*     }
* }
* @endcode

/**
 * @brief Produce and send a single message to broker.
 *

```

```

* \p rkt is the target topic which must have been previously created with
* `rd_kafka_topic_new()`.
*
* `rd_kafka_produce()` is an asynch non-blocking API.
*
* \p partition is the target partition, either:
* - RD_KAFKA_PARTITION_UA (unassigned) for
*   automatic partitioning using the topic's partitioner function, or
* - a fixed partition (0..N)
*
* \p msgflags is zero or more of the following flags OR'ed together:
* RD_KAFKA_MSG_F_FREE - rdkafka will free(3) \p payload when it is done
*                       with it.
* RD_KAFKA_MSG_F_COPY - the \p payload data will be copied and the
*                       \p payload pointer will not be used by rdkafka
*                       after the call returns.
*
* .._F_FREE and .._F_COPY are mutually exclusive.
*
* If the function returns -1 and RD_KAFKA_MSG_F_FREE was specified, then
* the memory associated with the payload is still the caller's
* responsibility.
*
* \p payload is the message payload of size \p len bytes.
*
* \p key is an optional message key of size \p keylen bytes, if non-NULL it
* will be passed to the topic partitioner as well as be sent with the
* message to the broker and passed on to the consumer.
*
* \p msg_opaque is an optional application-provided per-message opaque
* pointer that will be provided in the delivery report callback (`dr_cb`) for
* referencing this message.
*
* Returns 0 on success or -1 on error in which case errno is set
* accordingly:
* - ENOBUFS - maximum number of outstanding messages has been reached:
*             "queue.buffering.max.messages"
*             (RD_KAFKA_RESP_ERR__QUEUE_FULL)
* - EMSGSIZE - message is larger than configured max size:
*             "messages.max.bytes".
*             (RD_KAFKA_RESP_ERR_MSG_SIZE_TOO_LARGE)
* - ESRCH - requested \p partition is unknown in the Kafka cluster.
*           (RD_KAFKA_RESP_ERR__UNKNOWN_PARTITION)
* - ENOENT - topic is unknown in the Kafka cluster.
*           (RD_KAFKA_RESP_ERR__UNKNOWN_TOPIC)
*
* @sa Use rd_kafka_errno2err() to convert `errno` to rdkafka error code.

 */

/**
 * @brief Adds one or more brokers to the kafka handle's list of initial
 *        bootstrap brokers.
 *
 * Additional brokers will be discovered automatically as soon as rdkafka
 * connects to a broker by querying the broker metadata.
 *
 * If a broker name resolves to multiple addresses (and possibly
 * address families) all will be used for connection attempts in
 * round-robin fashion.
 *
 * \p brokerlist is a , -separated list of brokers in the format:
 *   \c \<broker1\>,\<broker2\>,...
 * Where each broker is in either the host or URL based format:
 *   \c \<host\>[:\<port\>]
 *   \c \<proto\>://\<host\>[:port]
 * \c \<proto\> is either \c PLAINTEXT, \c SSL, \c SASL, \c SASL_PLAINTEXT
 * The two formats can be mixed but ultimately the value of the
 * `security.protocol` config property decides what brokers are allowed.
 *
 * Example:
 *   brokerlist = "broker1:10000,broker2"
 *   brokerlist = "SSL://broker3:9000,ssl://broker2"
 *
 * @returns the number of brokers successfully added.
 *

HPE Data Fabric Streams Python Applications

As of HPE Data Fabric 5.2.1, you can create python applications for HPE Data Fabric Streams using the HPE Data Fabric Streams Python client. The HPE Data Fabric Streams Python client is a binding for librdkafka and the HPE Data Fabric Streams C Client is a distribution of librdkafka that works with HPE Data Fabric Streams.

The HPE Data Fabric Streams Python client is available in a Ecosystem Pack (EEP) starting with EEP 3.0.

The following Apache Kafka librdkafka versions are supported:

Table

Core release	EEP Release	Kafka librdkafka version
As of HPE Data Fabric 7.10.0	As of 9.4.0	2.6.0
As of HPE Data Fabric 7.9.0	As of 9.3.1	2.0.2*
As of HPE Data Fabric 6.0.1	As of 5.0	0.11.3
As of HPE Data Fabric 5.2.1 through 6.0.0	As of 3.0	0.9.0

*Librdkafka 2.0.2 in core 7.9 is **not** compatible with HPE Data Fabric Stream clients for Python or C# applications. Nodes running Python or C# applications should not be upgraded to HPE Data Fabric 7.9.

NOTE: Because the HPE Data Fabric Streams Python Client is dependent on the HPE Data Fabric Streams C Client, the HPE Data Fabric Streams C Client must be configured before using the HPE Data Fabric Streams Python Client.

When developing and running HPE Data Fabric Streams Python applications, note the following points:

- You can create producers and high-level consumers. Low-level consumers are not supported.
- Consuming or producing topics in a Kafka cluster is not supported.
- HPE Data Fabric Streams offset values start at 1, not 0.
- HPE Data Fabric security is supported including ACLs and ACEs for authorization. The unique Kafka security features that are part of Apache Kafka are not supported. See [Security](#) on page 901 for more information about HPE Data Fabric security features.
- User impersonation is not supported.

Synchronous Consumer Partition Assignment

See [Synchronous Consumer Partition Assignment for Streams](#) on page 4572

Developing HPE Data Fabric Streams Python Applications

This topic includes basic information about how to develop a HPE Data Fabric Streams Python application and an example program that you can run.

Before you Begin

Confirm that your environment meets the following requirements:

- HPE Data Fabric cluster version 5.2.1 or greater.
- HPE Data Fabric core client (mapr-client) package. See [Installing the Data Fabric Client \(Non-FIPS\)](#) on page 361 for more information.
- HPE Data Fabric Streams C Client (mapr-librdkafka) is installed and configured on the node. See [Configuring the HPE Data Fabric Streams C Client](#) on page 4007.

- HPE Data Fabric Streams Python Client (mapr-streams-python) is installed on the node. See [Installing HPE Data Fabric Streams Python Client](#) on page 310.
- Python installed on the node.
 - For a cluster running Release 7.9 or a lower version core, Python version 2.7.x and above, up to version 3.6.x.
 - For a cluster running Release 7.10 or a higher version core, Python version 3.7 up to version 3.12.

Create a HPE Data Fabric Streams Producer Application

In general, you want to create a producer that performs the following steps:

1. Import the producer class.
2. Define the producer and its configuration.
3. Produce data.
4. Wait for all messages to be sent to consumer.

As of EEP 5.0 HPE Data Fabric Streams Python Client: In the following example code, three messages are produced to a topic named mytopic in a stream named my_stream.

```
from confluent_kafka import Producer
p = Producer({'streams.producer.default.stream': '/my_stream'})
some_data_source= ["msg1", "msg2", "msg3"]
for data in some_data_source:
    p.produce('mytopic', data.encode('utf-8'))
    p.flush()
```

Create a HPE Data Fabric Streams Consumer Application

In general, you want to create a consumer that performs the following steps:

1. Import the consumer class.
2. Define the consumer and its configuration.
3. Consume data.
4. Wait for all messages to be consumed.

As of EEP 5.0 HPE Data Fabric Streams Python Client: In following example code, the HPE Data Fabric Streams consumer is subscribed to my_stream/mytopic and it prints the content of each message that it reads.

```
from confluent_kafka import Consumer, KafkaError
c = Consumer({'group.id': 'mygroup',
              'default.topic.config': {'auto.offset.reset': 'earliest'}})
c.subscribe(['/my_stream:mytopic'])
running = True
while running:
    msg = c.poll(timeout=1.0)
    if msg is None: continue
    if not msg.error():
        print('Received message: %s' % msg.value().decode('utf-8'))
    elif msg.error().code() != KafkaError._PARTITION_EOF:
        print(msg.error())
```

```
running = False
c.close()
```

Run the Example Applications

To run the sample producer and consumer applications:

1. Create a stream named `mystream`.
2. Create a file named `producer.py`.
3. Add the producer example code into the `producer.py` file.
4. Create a file named `consumer.py`.
5. Add the consumer example code into the `consumer.py` file.
6. Verify that you have completed the steps to configure the HPE Data Fabric Streams C client or complete the steps now. See [Configuring the HPE Data Fabric Streams C Client](#) on page 4007.

NOTE: The HPE Data Fabric Streams Python Client is dependent on the HPE Data Fabric Streams C Client. Therefore, the HPE Data Fabric Streams C Client must be configured before you can run the application.

7. Run `producer.py` from the command line to generate messages.

```
$ python producer.py
```

8. Run `consumer.py` from the command line:

```
$ python consumer.py
```

Migrating Kafka Python Applications to HPE Data Fabric Streams

With some modification, you can use existing confluent-kafka python applications to consume and produce topics in HPE Data Fabric Streams. The HPE Data Fabric Streams Python Client is a binding for Apache librdkafka that works with HPE Data Fabric Streams.

1. Install the HPE Data Fabric Streams Python Client.

NOTE: This required that you also install and configure the HPE Data Fabric Streams C Client. See [Configuring the HPE Data Fabric Streams C Client](#) on page 4007.

2. Do one of the following depending on whether you are using the EEP 5.0 (or higher) HPE Data Fabric Streams Python Client or the EEP 3.0 (or higher) HPE Data Fabric Streams Python Client.
 - If you are using HPE Data Fabric Streams Python EEP 5.0 (or higher), skip this step. The references to `confluent_kafka` should be retained.
 - If you are using HPE Data Fabric Streams Python EEP 3.0 (or higher), update import statements to refer to the MapR Stream Python API. References to `confluent_kafka` should be updated to `mapr_streams_python`.

NOTE: For example, update from `confluent_kafka import Consumer` to `from mapr_streams_python import Consumer`.

- When you refer to a topic in the application code, include the path and name of the stream in which the topic is located:

```
/<path and name of stream>:<name of topic>
```

For example, you might have a stream in a HPE Data Fabric cluster that is named `stream_A`, and the stream might be in a volume named `IoT` and in a directory named `automobile_sensors`. You want to redirect a producer application to a topic in that stream. The syntax of the path to the topic might look like this: `/mapr/IoT/automobile_sensors/stream_A:<name of topic>`.

NOTE: Optionally, use the `streams.consumer.default.stream` and `streams.producer.default.stream` configuration parameters. When you configure these parameters, applications can specify just the topic name to write or read from the default stream.

- Review the APIs that are supported and make changes to your application, as needed. See [API for HPE Data Fabric Streams Python Client](#) on page 4545.
- See [Configuration Properties for HPE Data Fabric Streams Python Client](#) on page 4551 for the list of supported configuration parameters and make changes to your application, as needed.

NOTE: SSL-related configuration parameters are ignored. When you set these parameters, the HPE Data Fabric Streams Client issues a warning indicating that the parameters are not supported.

API for HPE Data Fabric Streams Python Client

HPE Data Fabric Streams Python Client is a binding for `librdkafka` and it supports the following APIs.

As of HPE Data Fabric 5.2.1, you can create python applications for HPE Data Fabric Streams using the HPE Data Fabric Streams Python client. The HPE Data Fabric Streams Python client is a binding for `librdkafka` and the HPE Data Fabric Streams C Client is a distribution of `librdkafka` that works with HPE Data Fabric Streams.

Table

Core release	EEP Release	Kafka librdkafka version
As of HPE Data Fabric 7.10.0	As of 9.4.0	2.6.0
As of HPE Data Fabric 6.0.1	As of 5.0	0.11.3
As of HPE Data Fabric 5.2.1 through 6.0.0	As of 3.0	0.9.0

class mapr_streams_python.Consumer

A high-level Kafka Consumer.

Method	Behavior
<code>Consumer(**kwargs)</code>	Create new Consumer instance using provided configuration dictionary.
<code>assign(partitions)</code>	Set consumer partition assignment to the provided list of TopicPartition and starts consuming. Parameters(s): <ul style="list-style-type: none"> <code>partitions (list(TopicPartition))</code> – List of topic+partitions and optionally initial offsets to start consuming

Method	Behavior
unassign()	<p>Unassign from all TopicPartitions that have been assigned with the <code>.assign(*topic_partition_list)</code> method.</p> <p> NOTE: This method is applicable as of HPE Data Fabric Streams Python Client EEP 5.0 which is associated with librdkafka 0.11.3.</p>
assignment()	<p>Return a list of assignments for a consumer object.</p> <p> NOTE: This method is applicable as of HPE Data Fabric Streams Python Client EEP 5.0 which is associated with librdkafka 0.11.3.</p>
close()	<p>Close down and terminate the Kafka Consumer.</p> <p>Actions(s):</p> <ul style="list-style-type: none"> • Stops consuming • Commits offsets • Leave consumer group
commit([message=None][, offsets=None][, async=True])	<p>Commit a message or a list of offsets.</p> <p>Message and offsets are mutually exclusive, if neither is set the current partition assignment's offsets are used instead.</p> <p>Parameters(s):</p> <ul style="list-style-type: none"> • message (confluent_kafka.Message) – Commit message's offset+1. • offsets (list(TopicPartition)) – List of topic+partitions+offsets to commit. • async (bool) – Asynchronous commit, return immediately.
committed(partitions[, timeout=None])	<p>Retrieve committed offsets for the list of partitions.</p> <p>Parameters(s):</p> <ul style="list-style-type: none"> • partitions (list(TopicPartition)) - List of topic+partitions to query for stored offsets. • timeout (float) – Request timeout <p>Returns: List of topic+partitions with offset and possibly error set.</p> <p>Return type: list(TopicPartition)</p> <p>Raises: KafkaException</p> <p> NOTE: As of HPE Data Fabric 6.0, the message offset in a partition starts from zero (0). If you are upgrading and do not enable the HPE Data Fabric Database/HPE Data Fabric Streams feature, mfs.feature.db.streams.v6.support, the message offset in a partition starts from one (1).</p>

Method	Behavior
<code>on_commit(err, partitions)</code>	<p>A callback for <code>Consumer.commit()</code> that triggers custom actions when a commit request completes.</p> <p>Parameters(s):</p> <ul style="list-style-type: none"> <code>err</code> (<code>KafkaError</code>) – Commit error object, or <code>None</code> on success. <code>Partitions</code> (<code>list(TopicPartition)</code>) – List of partitions with their committed offsets or per-partition errors
<code>poll([timeout=None])</code>	<p>Consume messages, calls callbacks and returns events.</p> <p>The application must check the returned <code>Message</code> object's <code>Message.error()</code> method to distinguish between proper messages (<code>error()</code> returns <code>None</code>), or an event or error (see <code>error().code()</code> for specifics).</p> <p>Parameter(s): <code>timeout</code> (<i>float</i>) – Maximum time to block waiting for message, event or callback</p> <p>Returns: A <code>Message</code> object or <code>None</code> on timeout</p> <p>Return type: <code>Message</code> or <code>None</code></p>
<code>position(partitions[, timeout=None])</code>	<p>Retrieve current positions (offsets) for the list of partitions.</p> <p>Parameter(s): <code>partitions</code> (<code>list(TopicPartition)</code>) – List of topic+partitions to return current offsets for. The current offset is the offset of the last consumed message + 1</p> <p>Returns: List of topic+partitions with offset and possibly error set.</p> <p>Return type: <code>list(TopicPartition)</code></p> <p>Raises: <code>KafkaException</code></p> <p>This function returns 0 when the messages have not yet been consumed from partitions. <code>librdkafka</code> returns -1001 instead.</p>
<code>subscribe(topics[, listener=None])</code>	<p>Set subscription to supplied list of topics This replaces a previous subscription.</p> <p>Parameters:</p> <ul style="list-style-type: none"> <code>topics</code> (<code>list(str)</code>) – List of topics (strings) to subscribe to. <code>on_assign</code> (callable) – callback to provide handling of customized offsets on completion of a successful partition re-assignment. <code>on_revoke</code> (callable) – callback to provide handling of offset commits to a customized store on the start of a rebalance operation. <p>Raises: <code>KafkaException</code></p> <p> NOTE: You cannot use the <code>rd_kafka_subscribe</code> API to subscribe a consumer to topics when that consumer is already assigned to topics. If you call this API for an assigned consumer, error <code>RD_KAFKA_RESP_ERR__CONFLICT</code> is returned.</p>
<code>on_assign(consumer, partitions)</code>	Same as <code>librdkafka</code> .

Method	Behavior
unsubscribe()	Same as librdkafka.
on_revoke(consumer, partitions)	Parameter(s): <ul style="list-style-type: none"> consumer (Consumer) – Consumer instance. partitions (list(TopicPartition)) – Absolute list of partitions being assigned or revoked.
get_watermark_offsets(confluent_kafka.TopicPartition)	Get WatermarkOffsets for a given Topic Partition. Parameter(s): TopicPartition - Gets the watermark offset  NOTE: This method is applicable as of HPE Data Fabric Streams Python Client EEP 5.0 which is associated with librdkafka 0.11.3.

class mapr_streams_python.Producer

Asynchronous Kafka Producer.

Method	Behavior
Producer(**kwargs)	Create new Producer instance using provided configuration dict.
len()	This API returns a positive number to indicate that messages are waiting to be produced to a streams topic but the value does not indicate the actual number of messages. librdkafka returns the actual number of messages that are waiting to be sent to or acknowledged by the broker. Return type: int
flush()	Wait for all messages in the Producer queue to be delivered. This is a convenience method that calls poll() until len() is zero.
poll([timeout])	Polls the producer for events and calls the corresponding callbacks (if registered). Parameter(s): <ul style="list-style-type: none"> timeout (float) – Maximum time to block waiting for events Returns: Number of events processed (callbacks served). Return type: int

Method	Behavior
produce(topic[, value][, key][, partition][, callback])	<p>Produce message to topic. This is an asynchronous operation, an application may use the callback(alias on_delivery) argument to pass a function (or lambda) that will be called from poll() when the message has been successfully delivered or permanently fails delivery.</p> <p>Parameters:</p> <ul style="list-style-type: none"> • topic (str) – Topic to produce message to • value (str bytes) – Message payload • key (str bytes) – Message key • partition (int) – Partition to produce to, else uses the configured partitioner. • on_delivery(err,msg) (func) – Delivery report callback to call (from poll() or flush()) on successful or failed deliver <p>Raises:</p> <ul style="list-style-type: none"> • BufferError – if the internal producer message queue is full (queue.buffering.max.messages exceeded) • KafkaException – for other errors, see exception code <p> NOTE: When this function is called with NULL payload, an invalid argument error is sent to the callback. librdkafka creates a message with NULL payload and key value instead.</p>

class mapr_streams_python.Message

The Message object represents either a single consumed or produced message, or an event . An application must check with error() to see if the object is a proper message (error() returns None) or an error/event. This class is not user-instantiable.

Method	Behavior
len()	<p>Returns: Message value (payload) size in bytes.</p> <p>Return type: int</p>
error()	<p>The message object is also used to propagate errors and events. Applications must check error() to determine if the Message is a proper message (error() returns None) or an error or event (error() returns a KafkaError object)</p> <p>Return type: None or KafkaError</p>
key()	<p>Returns: message key or None if not available</p> <p>Return type: str bytes or None</p>
offset()	<p>Returns: message offset or None if not available</p> <p>Return type: int or None</p>
partition()	<p>Returns: partition number or None if not available</p> <p>Return type: int or None</p>

Method	Behavior
topic()	Returns: topic name or None if not available Return type: str or None
value()	Returns: message value (payload) or None if not available Return type: str bytes or None
timestamp()	Returns: message timestamp  NOTE: This method is applicable as of HPE Data Fabric Streams Python Client EEP 5.0 which is associated with librdkafka 0.11.3.

class `mapr_streams_python.TopicPartition`

TopicPartition is a generic type to hold a single partition and various information about it. It is typically used to provide a list of topics or partitions for various operations, such as `Consumer.assign()`.

Method	Behavior
<code>TopicPartition(topic[, partition][, offset])</code>	Instantiate a TopicPartition object. Parameter(s) <ul style="list-style-type: none"> • <code>topic</code> (string) – Topic name • <code>partition</code> (int) – Partition id • <code>offset</code> (int) – Initial partition offset Return type: TopicPartition
<code>error</code>	Attribute that indicates an error (with <code>KafkaError</code>) unless None.
<code>offset</code>	Attribute for offset.
<code>partition</code>	Attribute for partition number.
<code>topic</code>	Attribute for topic name.

class `mapr_streams_python.KafkaError`

Kafka error and event object.

The `KafkaError` class serves multiple purposes:

- Propagation of errors
- Propagation of events
- Exceptions

This class is not user-instantiable.

Method	Behavior
code()	Returns the error/event code for comparison to <code>KafkaError.ERR_CONSTANTS</code> . Returns: error/event code Return type: int
name()	Returns the enum name for error/event. Returns: error/event enum name string Return type: str
str()	Returns the human-readable error/event string. Returns: error/event enum message string Return type: str

Configuration Properties for HPE Data Fabric Streams Python Client

In the instance constructor of a HPE Data Fabric Streams Python application, you can use a dictionary to set the following configuration properties. HPE Data Fabric Streams Python client supports a superset of the configuration properties supported by the HPE Data Fabric Streams C client.

Global Configuration Properties

Property Name	Behavior
client.id	Same as librdkafka
default.topic.config	A dictionary of topic-level configuration properties that are applied to all used topics for the instance.
message.max.bytes	Supports a value less than or equal to 10MB (10000000). If this property is set to a value that is higher than 10MB, the client issues a warning and sets the configuration to 10MB. Produce calls fail when the message size is greater than 10MB.
receive.message.max.bytes	Same as librdkafka
topic.blacklist	Same as librdkafka
error_cb	A callback for generic/global error events. This callback is served by <code>poll()</code> .
opaque	Same as librdkafka.

Consumer Configuration Properties

Property Name	Behavior
group.id	Same as librdkafka.
enable.auto.commit	Same as librdkafka.
auto.commit.interval.ms	Same as librdkafka.
rebalance_cb	Same as librdkafka.
offset_commit_cb	Same as librdkafka.
delivery.report.only.error	Same as librdkafka.
dr_msg_cb	Same as librdkafka.

Property Name	Behavior
on_commit	A callback used to indicate success or failure of commit requests.

Topic Configuration Properties

Property Name	Behavior
partitioner_cb	Same as librdkafka.
auto.offset.reset	Supports the following values: earliest, latest, none, smallest, and largest. librdkafka also supports biggest, end and error.

Producer Configuration Properties

Property Name	Behavior
on_delivery(kafka.KafkaError, kafka.Message)	A Python function reference that is called once for each produced message to indicate the final delivery result (success or failure). This property may also be set per-message by passing callback=callable (or on_delivery=callable) to the confluent_kafka.Producer.produce() function.

HPE Data Fabric-Specific Configuration Properties

Property Name	Behavior
streams.consumer.default.stream	<p>Specifies the path and name of the stream that the consumer subscribes to if, when subscribing to a topic, the consumer does not specify a stream. For example, the consumer can specify the name of a stream together with the name of a topic to write to, like this: / <stream>:<topic>.</p> <p> NOTE: rd_kafka_list groups API uses this consumer configuration to obtain the consumer groups.</p>
streams.parallel.flushers.per.partition	Enables the producer may have multiple parallel send requests to the server for each topic partition. If this setting is set to true, it is possible for messages to be sent out of order.
streams.producer.default.stream	<p>Specifies the stream that the producer will use by default if the producer does not provide the name of a stream when specifying a topic to write to. For example, the producer can specify the name of a stream together with the name of a topic to write to, like this: / <stream>:<topic>. However, if the stream is not specified, the value of this configuration parameter is assumed to be the stream in which the topic is located. If the producer specifies the name of a topic without also providing the path and name of the stream, and there is no value for this configuration parameter, HPE Data Fabric Streams assumes that the topic specified is in Apache Kafka and does nothing.</p>

Additional Information

Here is a consumer configuration example:

```
conf = {'group.id': 'mygroup',
'session.timeout.ms': 6000,
'on_commit': my_commit_callback,
'default.topic.config': {'auto.offset.reset': 'smallest'}}
consumer = mapr_streams_python.Consumer(**conf)
```

HPE Data Fabric Streams C#/.NET Applications

As of HPE Data Fabric 6.0.1/EEP5.0, you can create C#/.NET applications for HPE Data Fabric Streams using the HPE Data Fabric Streams C#/.NET client. The HPE Data Fabric Streams C#/.NET client is a binding for librdkafka and the HPE Data Fabric Streams C Client is a distribution of librdkafka that works with HPE Data Fabric Streams.

Requirements

- HPE Data Fabric Client on Windows 7 (or higher) x64 operating systems
- HPE Data Fabric cluster version 6.0.1 or greater
- Java 8 SDK and set Java HOME
- HPE Data Fabric Streams C Client (mapr-librdkafka 0.11.3)
- HPE Data Fabric Streams C#/.NET Client (mapr-streams-dotnet)
- .NET SDK 4.5.x or 4.6.x or .NET Core SDK 1.1
- nuget.exe

See [Installing HPE Data Fabric Streams C#/.NET Client](#) on page 312 for installation information.

General Information

When developing and running HPE Data Fabric Streams C#/.NET applications, note the following points:

- You can create producers and high-level consumers. Low-level consumers are not supported.
- Consuming or producing topics in a Kafka cluster is not supported.
- HPE Data Fabric Streams offset values start at 1, not 0.
- HPE Data Fabric security is supported including ACLs and ACEs for authorization. The unique Kafka security features that are part of Apache Kafka are not supported. See [Security](#) on page 901 for more information about HPE Data Fabric security features.
- User impersonation is not supported.

Synchronous Consumer Partition Assignment

See [Synchronous Consumer Partition Assignment for Streams](#) on page 4572

Developing HPE Data Fabric Streams C#.NET Applications

Describes general tasks for developing C#.NET applications.

Before Your Begin

Confirm that your environment meets the following requirements:

- HPE Data Fabric cluster version 6.0.1 or greater.
- HPE Data Fabric Streams C Client (mapr-librdkafka 0.11.3) is installed and configured on the node. See [Configuring the HPE Data Fabric Streams C Client](#) on page 4007.
- HPE Data Fabric Streams C#.NET Client (mapr-streams-dotnet) is installed on the node.
- .NET SKD 4.5.x or 4.6.x
- .NET Core SDK 1.1
- nuget.exe

Create a Producer Application

In general, you want to create a producer that performs the following steps:

1. Import the producer class.
2. Define the producer and its configuration.
3. Produce data.
4. Wait for all messages to be sent to consumer.

In the following example code, three messages are produced to a topic named mytopic in a stream named my_stream.

```

class Producer
{
    public static async void Produce()
    {
        string stream = "/my_stream";
        string topicName = "mytopic";

        var config = new Dictionary<string, object>
        { { "streams.producer.default.stream", stream } };
        var messages = new string[] { "Msg1", "Msg2", "Msg3" };

        using (var producer = new Producer<Null, string>(config, null,
        new StringSerializer(Encoding.UTF8)))
        {
            foreach (var msg in messages)
            {
                var deliveryReport = await
                producer.ProduceAsync(topicName, null, msg);
                Console.WriteLine($"Delivery report:
                {deliveryReport.TopicPartitionOffset}");
            }

            producer.Flush(TimeSpan.FromSeconds(1));
        }
    }
}

```

```

    }
}
}

```

Create a Consumer Application

In general, you want to create a consumer that performs the following steps:

1. Import the consumer class.
2. Define the consumer and its configuration.
3. Consume data.
4. Wait for all messages to be consumed.

In following example code, the HPE Data Fabric Streams consumer is subscribed to my_stream/mytopic and it prints the content of each message that it reads.

```

using Confluent.Kafka;
using Confluent.Kafka.Serialization

class Consumer
{
    public static void Consume()
    {
        var stream = "/mystream";
        var topic = "mytopic";

        var config = new Dictionary<string, object>
        {
            { "group.id", "simple-csharp-consumer" },
            { "streams.consumer.default.stream", stream }
        };

        bool running = true;

        using (var consumer = new Consumer<Ignore, string>(config,
null, new StringDeserializer(Encoding.UTF8)))
        {
            var l = new List<TopicPartitionOffset> { new
TopicPartitionOffset(topic, 0, 0) };
            consumer.Assign(l);

            // Raised on critical errors, e.g. connection failures.
            consumer.OnError += (_, error) =>
            {
                Console.WriteLine($"Error: {error}");
                running = false;
            };

            // Raised on deserialization errors or when a consumed
message has an error != NoError.
            consumer.OnConsumeError += (_, error) =>
            {
                Console.WriteLine($"Consume error: {error}");
                running = false;
            };

            while (running)
            {

```

```

        Message<Ignore, string> msg;
        if (consumer.Consume(out msg, TimeSpan.FromSeconds(10)))
        {
            Console.WriteLine($"Topic: {msg.Topic} Partition:
{msg.Partition} Offset: {msg.Offset} {msg.Value}");
        }
    }
}
}
}

```

Run the Example Applications

To run the sample producer and consumer applications:

1. Create a stream named **mystream**.
2. Create a folder application.
3. Create a file named **example.cs**.
4. Add producer example code into the **example.cs** file.
5. Add consumer example code into the **example.cs** file.
6. Add an entry point for your application:

```

class Demo
{
    public static void Main(string[] args)
    {
        Producer.Produce();
        Consumer.Consume();
    }
}

```

7. Create a project file named **example.csproj**.

8. Add the following dependency properties into the **example.csproj** file:

```
<?xml version="1.0" encoding="utf-8"?>
<Project ToolsVersion="15.0" xmlns="http://schemas.microsoft.com/
developer/msbuild/2003">
  <Import Project="$(MSBuildExtensionsPath)\$(MSBuildToolsVersion)
\Microsoft.Common.props" Condition="Exists('$(MSBuildExtensionsPath)\$
(MSBuildToolsVersion)\Microsoft.Common.props')" />
  <PropertyGroup>
    <Configuration Condition=" '$(Configuration)' == '' ">Debug</
Configuration>
    <Platform Condition=" '$(Platform)' == '' ">AnyCPU</Platform>
    <ProjectGuid>{99EDBA4B-D7DA-48BB-8D0C-AF4B12387935}</ProjectGuid>
    <OutputType>Exe</OutputType>
    <RuntimeIdentifiers>win10-x64</RuntimeIdentifiers>
    <RootNamespace>app</RootNamespace>
    <AssemblyName>app</AssemblyName>
    <TargetFrameworkVersion>v4.6.1</TargetFrameworkVersion>
    <FileAlignment>512</FileAlignment>
    <AutoGenerateBindingRedirects>true</AutoGenerateBindingRedirects>
  </PropertyGroup>
  <PropertyGroup Condition=" '$(Configuration)|$(Platform)' == 'Debug|
AnyCPU' ">
    <PlatformTarget>AnyCPU</PlatformTarget>
    <DebugSymbols>true</DebugSymbols>
    <DebugType>full</DebugType>
    <Optimize>>false</Optimize>
    <OutputPath>bin\Debug\</OutputPath>
    <DefineConstants>DEBUG;TRACE</DefineConstants>
    <ErrorReport>prompt</ErrorReport>
    <WarningLevel>4</WarningLevel>
  </PropertyGroup>
  <ItemGroup>
    <Compile Include="app.cs" />
  </ItemGroup>
  <ItemGroup>
    <PackageReference Include="mapr-streams-dotnet" Version="0.11.3" />
  </ItemGroup>
  <Import Project="$(MSBuildToolsPath)\Microsoft.CSharp.targets" />
</Project>
```

9. Verify that you have completed the steps to configure the HPE Data Fabric Streams C client or complete the steps now. See [Configuring the HPE Data Fabric Streams C Client](#) on page 4007.

NOTE: The HPE Data Fabric Streams C#.NET Client is dependent on the HPE Data Fabric Streams C Client. Therefore, the HPE Data Fabric Streams C Client must be configured before you can run the application.

10. Open your project folder on the command line and run:

```
dotnet run
```

Migrating Kafka C#.NET Applications to HPE Data Fabric Streams

With some modification, you can use existing confluent-kafka C#.NET applications to consume and produce topics in HPE Data Fabric Streams. The HPE Data Fabric Streams C#.NET Client is a binding for Apache librdkafka that works with HPE Data Fabric Streams.

Migrating a .NET 4.5 or 4.6 Application

NOTE: This migration information is applicable for Windows (Win7-x64) platform *only*.

To migrate an existing .NET 4.5 or 4.6 application:

1. Install and configure the HPE Data Fabric Streams C Client. See [Configuring the HPE Data Fabric Streams C Client](#) on page 4007.
2. Replace the librdkafka.dll with the HPE Data Fabric librdkafka 0.11.3 from **/bin/.../runtimes/<win7-x64>/<native folder>**.
3. Add a symlink from the **MapRClient.dll** to the **librdkafka.dll**.
4. Restart the application.

Migrating a .NET Core Application1

NOTE: This migration information is applicable for Windows (Win7-x64) and Linux platforms.

To migrate an existing .NET Core application:

1. Install and configure the HPE Data Fabric Streams C Client. See [Configuring the HPE Data Fabric Streams C Client](#) on page 4007.
2. Replace the librdkafka.dll with the MapR librdkafka 0.11.3 from **USER_HOME/.NUGET/PACKAGES/LIBRDKAFKA.REDIST/0.11.3/runtimes/<platform>/<native folder>**.
3. Add a symlink from the **MapRClient.dll** to the **librdkafka.dll**.
4. Restart the application.

Migrating a .NET Core Application2

NOTE: This migration information is applicable for Linux platforms *only*.

To migrate an existing .NET Core application:

1. Remove all **.so** files from the **~/ .NUGET/PACKAGES/LIBRDKAFKA.REDIST/0.11.3/runtimes/<platform>/<native folder>** directory.
2. Install and configure the HPE Data Fabric Streams C Client. See [Configuring the HPE Data Fabric Streams C Client](#) on page 4007.
3. Replace the librdkafka.dll with the MapR librdkafka 0.11.3 from **USER_HOME/.NUGET/PACKAGES/LIBRDKAFKA.REDIST/0.11.3/runtimes/** directory.
4. If the MapR Client doesn't install into the LD search path, add a symlink from the **MapRClient.dll** to the **/usr/local/lib**.
5. Restart the application.

General Migration Information

- When you refer to a topic in the application code, include the path and name of the stream in which the topic is located:

```
/<path and name of stream>:<name of topic>
```

For example, you might have a stream in a MapR cluster that is named stream_A, and the stream might be in a volume named IoT and in a directory named automobile_sensors. You want to redirect a producer application to a topic in that stream. The syntax of the path to the topic might look like this: /mapr/IoT/automobile_sensors/stream_A:<name of topic>.

NOTE: Optionally, use the `streams.consumer.default.stream` and `streams.producer.default.stream` configuration parameters. When you configure these parameters, applications can specify just the topic name to write or read from the default stream.

- Review the APIs that are supported and make changes to your application, as needed. See [API for HPE Data Fabric Streams C#/ .NET](#) on page 4559.
- See [Configuration Properties for HPE Data Fabric Streams C#/ .NET Client](#) on page 4561 for the list of supported configuration parameters and make changes to your application, as needed.

NOTE: SSL-related configuration parameters are ignored. When you set these parameters, the HPE Data Fabric Streams Client issues a warning indicating that the parameters are not supported.

API for HPE Data Fabric Streams C#/ .NET

HPE Data Fabric Streams C#/ .NET Client is a binding for librdkafka and the HPE Data Fabric Streams C Client is a distribution of librdkafka that works with HPE Data Fabric Streams.

Table

Core release	EEP Release	Kafka librdkafka version
As of HPE Data Fabric 6.0.1	As of 5.0	0.11.3

Classes

Classes	Description
CommittedOffsets	Encapsulates information provided to a Consumer's OnOffsetsCommitted event - per-partition offsets and success/error together with overall success/error of the commit operation.
Consumer	Implements a high-level Apache Kafka consumer (without deserialization).
Consumer<TKey, TValue>	Implements a high-level Apache Kafka consumer (with key and value deserialization).
Error	Represents an error that occurred when interacting with a Kafka broker or the librdkafka library.
ErrorCodeExtensions	Provides extension methods on the ErrorCode enumeration.
GroupInfo	Encapsulates information describing a particular Kafka group.
GroupMemberInfo	Encapsulates information describing a particular member of a Kafka group.

Classes	Description
Ignore	A type for use in conjunction with that enables message keys or values to be read as null, regardless of their value.
KafkaException	Represents an error that occurred during an interaction with Kafka.
Library	Methods that relate to the native librdkafka library itself (do not require a Producer or Consumer broker connection).
Loggers	OnLog callback event handler implementations.
LogMessage	Encapsulates information provided to the Producer/Consumer OnLog event.
Message	Represents a message stored in Kafka.
Message<TKey, TValue>	Represents a (deserialized) message stored in Kafka.
Metadata	Kafka cluster metadata.
Null	A type for use in conjunction with and that enables null key or values to be enforced when producing or consuming messages.
PartitionMetadata	Metadata pertaining to a single Kafka topic partition.
Producer	Implements a high-level Apache Kafka producer (without serialization).
Producer<TKey, TValue>	Implements a high-level Apache Kafka producer with key and value serialization.
TopicMetadata	Metadata pertaining to a single Kafka topic.
TopicPartition	Represents a Kafka (topic, partition) tuple.
TopicPartitionError	Represents a Kafka (topic, partition, error) tuple.
TopicPartitionOffset	Represents a Kafka (topic, partition, offset) tuple.
TopicPartitionOffsetError	Represents a Kafka (topic, partition, offset, error) tuple.
TopicPartitionTimestamp	Represents a Kafka (topic, partition, timestamp) tuple.
WatermarkOffsets	Represents the low and high watermark offsets of a Kafka topic/partition.

Interfaces

Interface	Description
IDeliveryHandler	This interface is implemented by types that handle delivery report callbacks as a result of calls to <code>Producer.ProduceAsync()</code> .
IDeliveryHandler<TKey, TValue>	This interface is implemented by types that handle delivery report callbacks as a result of calls to <code>Producer<TKey,TValue>.ProduceAsync()</code> .
ISerializingProducer<TKey, TValue>	This interface describes the minimum functionality to be provided by a high level (serializing) Kafka producer.

Structs

Struct	Description
Offset	Represents a Kafka partition offset value.
Timestamp	Encapsulates a Kafka timestamp and its type.

Enums

Enum	Description
ErrorCode	Enumeration of local and broker generated error codes.
TimestampType	Enumerates the different meanings of a message timestamp value.

Configuration Properties for HPE Data Fabric Streams C#.NET Client

Describes the C#.NET client configuration properties.

Global Configuration Properties

Property Name	
Behavior	
Same as librdkafka.	
Supports a value less than or equal to 10MB (10000000). If this property is set to a value that is higher than 10MB, the client issues a warning and sets the configuration to 10MB. Produce calls fail when the message size is greater than 10MB.	
Maximum bytes	

Property Name	
Behavior	Same as librdkafka.
Same as librdkafka.	
Same as librdkafka.	

Property Name	
Behavior	Same as librdkafka.
	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Data Fabric 6.0.1.
	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Data Fabric 6.0.1.

Consumer Configuration Properties

Behavior	
Same as librdkafka.	
Same as librdkafka.	
Same as librdkafka.	

Property Name	
Behavior	Same as librdkafka.
Usage	Same as librdkafka.
Security	Same as librdkafka.

<div>Property Name</div>	
<div>Behavior</div>	<div>Same as librdkafka.</div>
<div></div>	<div>Same as librdkafka.</div>

Topic Configuration

Property Name	
Behavior	Same as librdkafka.
	Supports the following values: beginning, end, earliest, latest, none, smallest, and largest. As of HPE Data Fabric 6.0.1, beginning and end are supported.
	 NOTE: librdkafka additionally supports error.

HPE Data Fabric-Specific Configurations

Property Name	
Behavior	
Description	<p>Specifies the path and name of the stream that the consumer subscribes to if, when subscribing to a topic, the consumer does not specify a stream. For example, the consumer can specify the name of a stream together with the name of a topic to write to, like this: /<stream>:<topic>.</p> <p> NOTE: rd_kafka_list groups API uses this consumer configuration to obtain the consumer groups.</p>

Property Name	Behavior
enableParallelSend	<p>Enables the producer to have multiple parallel send requests to the server for each topic partition. When this property is set to true, the default value, it is possible for messages to be sent out of order.</p>

Property Name	
Behavior	<p>Specifies the stream that the producer will use by default if the producer does not provide the name of a stream when specifying a topic to write to. For example, the producer can specify the name of a stream together with the name of a topic to write to, like this: /<stream>:<topic>. However, if the stream is not specified, the value of this configuration parameter is assumed to be the stream in which the topic is located. If the producer specifies the name of a topic without also providing the path and name of the stream, and there is no value for this configuration parameter, HPE Data Fabric Streams assumes that the topic specified is in Apache Kafka and does nothing.</p>

Utilities for HPE Data Fabric Streams

HPE Data Fabric Streams provides the utilities for operating on streams and topics.

 **NOTE:** HPE Data Fabric Streams cannot use HPE Data Fabric Database Shell to perform operations on streams or topics.

`mapr copystream`

This utility copies data from one HPE Data Fabric Stream to another HPE Data Fabric Stream. You can use it, for example, if you want to set up replication manually from one stream to another.

`mapr diffstreams`

This utility compares the message IDs, metadata, and data in two HPE Data Fabric Streams. Then, generates two directories that contain sequence files

mapr diffstreamswithcrc

that you can use to merge the rows from the two HPE Data Fabric Streams.

This utility uses a cyclic redundancy check to detect differences between sets of messages in the specified HPE Data Fabric Streams. Then, for each set of non-identical messages, it performs a detailed comparison. Finally, it generates one or more directories of sequence files.

mapr exportstream and mapr importstream

Use these utilities together to export data from HPE Data Fabric Streams into binary sequence files, and then import the data from the binary sequence files into other HPE Data Fabric Streams. You can also use the `mapr importstream` utility to import changes that are specified in sequence files output by the `mapr diffstreams` utility.

mapr perfconsumer

This utility runs a consumer reading messages from topics in a HPE Data Fabric Stream. Use this utility to run consumers when you want to estimate the performance of consumers for your HPE Data Fabric Streams applications, given your network configuration.

mapr perfproducer

This utility runs a producer, generating messages and publishing them to a HPE Data Fabric Stream. Use this utility to run producers when you want to estimate the performance of producers for your HPE Data Fabric Streams applications, given your network configuration.

mapr streamanalyzer

This light-weight utility, which is a sample application for the `Streams` Java class for analytics on HPE Data Fabric Streams, lets you count the messages in a stream or a subset of the topics in a stream. The utility also lets you print either whole retrieved messages or a subset of the fields in each message.

Configuring Properties for Message Size

Describes the `message.max.bytes` and `receive.message.max.bytes` properties for configuring message size.

message.max.bytes

For a C producer, the `message.max.bytes` value is 1000000 B by default.

The minimum value is 1000 B and maximum value is 32000000 B. The maximum message size produced by a C API is decided by the `message.max.bytes` value set on the C producer.

From C, Python, and C# APIs, the maximum message size that can be produced is 32000000 B. If a C consumer needs to consume a message that is greater than 32000000 B in size, which may be produced by a Java client, the consumer needs to update the `message.max.bytes` or `receive.message.max.bytes` properties to a higher value to consume it.

If the `message.max.bytes` property is set to greater than 32000000 B, it is by default capped at 32000000 B. Though a consumer can consume messages greater than 32000000 B (produced say by a Java client), only up to 32000000 B is produced from the Data Fabric C client. The maximum message

size consumed by a C API is limited by the value that is higher among the `message.max.bytes` and `receive.message.max.bytes` values.

receive.message.max.bytes

For a C consumer, the `receive.message.max.bytes` is 1000000 B by default. The minimum value is 1000 B and maximum value is 1000000000 B.

Using a Java API, a larger message size can be produced if the cluster-side property is changed using the following `maprcli config save` command:

```
Cluster side:

maprcli config save -values
{"mfs.db.max.rowsize.kb":<value in KB>}
```

In this case, the row size is 32 MB by default and the maximum is a little less than 2 GB.

The `mfs.db.max.rowsize.kb` setting is a cluster-wide setting that applies to HPE Data Fabric Database (Binary+JSON) and MapR Event Store for Apache Kafka, and it is not configurable per stream or topic.

Synchronous Consumer Partition Assignment for Streams

Describes synchronous consumer partition assignment for various applications that use Data Fabric Streams.

Synchronous Consumer Partition Assignment

As of HPE Data Fabric 7.8, synchronous consumer partition assignment is supported. For streams created with HPE Data Fabric 7.8 and later, this feature is enabled by default. To disable this feature, set `streams.async.subscription.callback.enabled=true` in `core-site.xml`. By default, this value is set to `false`.

With this feature enabled, consumer assignment updates occur synchronously within the `consumer.poll()` call in the user thread.

When setting a new consumer partition assignment, `consumer.assignment()` does not update until you invoke `consumer.poll()`.

NOTE: For the call to update, you might have to invoke `consumer.poll()` multiple times, or with a long enough timeout for assignment to be completed.

IMPORTANT: If you have an application that is set to sleep until consumer partition assignment is updated, you must perform one of the following actions to ensure the application continues to work as intended:

- Disable synchronous consumer partition assignment with `streams.async.subscription.callback.enabled=true` in `core-site.xml`.
- Enable the application to begin polling without the new user assignment.

MapReduce and Apps

This section contains information associated with developing YARN applications.

External Applications and Classpath

Describes how to configure the class path for external applications.

MapReduce version 2 applications require the `hadoop 2.x` or the `yarn` classpath, and other applications that can run on YARN require the `yarn` classpath.

The method to specify the classpath differs based on how the job or application is submitted:

Method used to Submit the Job	Method to Specify Classpath
The external application uses the <code>hadoop jar</code> or the <code>yarn jar</code> command.	YARN applications (MapReduce or custom applications) that are submitted using the <code>yarn jar</code> command will automatically use the <code>yarn</code> classpath. If the external application has a service that submits the job, you can set the <code>CLASSPATH</code> environment variable to point to a different classpath prior to starting the service. In this case, the <code>hadoop</code> classpath that you set in the <code>CLASSPATH</code> environment variable takes priority over the <code>hadoop</code> classpath for the <code>hadoop jar</code> command.
The external application does not use the <code>hadoop jar</code> or the <code>yarn jar</code> command.	Set the classpath using one of the following options: <ul style="list-style-type: none"> If the external application has a service that submits the job or application, you can set the <code>CLASSPATH</code> environment variable to point to the <code>hadoop</code> or <code>yarn</code> classpath prior to starting the service. Set the classpath within the application. Use one of the following methods to get the classpath: <ul style="list-style-type: none"> <code>hadoop2 classpath</code> or <code>hadoop -yarn classpath</code>: Gets the classpath for MRv2 applications. <code>yarn classpath</code>: Gets the classpath for YARN applications (MRv2 or other applications that can run on YARN).

IMPORTANT: When you launch a spring boot application, ensure that you prefix the classpath with `/opt/mapr/conf:/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop`. Alternatively, copy the `core-site.xml` file to the `/src/main/resources/` folder.

Classpath Construction

This section describes how the MapReduce classpath is constructed.

The classpath that is used to run a MapReduce program is constructed based on how the program is submitted.

When you submit an application from the command line, the classpath used to process the program is based on the following items in this order of priority:

1. JARs in the program's classpath, such as the `hadoop 2.x` or `yarn` classpath.
2. JARs specified with the `-libjar` parameter which can be appended to `hadoop jar` or `yarn jar` commands.

If an external application submits the application, the classpath that is used to process the jar file is based on the following items in this order of priority:

1. JARs in the classpath of the external application.

2. JARs in the program's classpath, such as the hadoop 2.x or yarn classpath.
3. JARs specified with `-libjar` parameter which can be appended to `hadoop jar` or `yarn jar` commands.

Managing Third-Party Libraries

Any third-party library that is required by a MapReduce program must be accessible to the data node that processes the application.

A data node is a node in the cluster that includes the NodeManager role. You can provide the third-party libraries when you submit the program, or you can install the third-party libraries on each node that processes the application.

Include the third-party libraries with each program

Including the third-party libraries with each program is the preferred method.

Perform one of the following operations to include the third-party jars when you submit the program:

- Package the third-party libraries with the MapReduce jar file. The benefit of this method is that the node from which you submit the program and the node that runs the program are not required to have the libraries files.
- Use the `-libjars` parameter to specify the third-party libraries on the command line. With this option, the library files are submitted to the data node along with the program. The benefit of this method is that the node that runs the program does not need to have the library files installed. However, the node that submits the program must have the library files installed.

Install the third-party libraries on each node that runs the program

You can also install the third-party libraries on each data node. However, this may not be preferred as there could be conflicts between library versions or library files.

To install the third-party libraries on each data node, perform one of the following operations:

- Install the third-party libraries in the following directory on each Node Manager node: `/opt/mapr/hadoop/hadoop-3.x/share/hadoop/common`
- On each node with the NodeManager role, install the required third-party libraries and then specify the location(s) of the third-party libraries with the `HADOOP_CLASSPATH` env variable in the `env_override.sh` file. The `env_override.sh` file is located in the following directory: `/opt/mapr/conf`. For more information about the file, see [About env_override.sh](#) on page 3467.

Kubernetes Interfaces for Data Fabric

This section describes how to leverage the capabilities of the Kubernetes Interfaces for Data Fabric.

Container Storage Interface (CSI) Storage Plugin Configuration

This section describes how to use and troubleshoot the Container Storage Interface (CSI) Storage Plugin.

See [Container Storage Interface \(CSI\) Storage Plugin Overview](#) on page 876 for more information.

Using the Container Storage Interface (CSI) Storage Plugin

This section describes how to configure for static and dynamic provisioning and mounting using example configuration files.

For an overview of the Container Storage Interface (CSI) Storage Plugin, see [Container Storage Interface \(CSI\) Storage Plugin Overview](#) on page 876.

Before You Begin CSI Configuration

Before configuring the Container Storage Interface (CSI) Storage Plugin, be sure to review the following notes about supported and unsupported features and parameters. For an overview of the Container Storage Interface (CSI) Storage Plugin, see [Container Storage Interface \(CSI\) Storage Plugin Overview](#) on page 876.

Data Fabric Parameters for Static and Dynamic Provisioning

In dynamic provisioning, you can specify parameters for the Data Fabric volume to be created. For a list of the parameters that you can use, see [volume create](#) on page 2929. Note these considerations for using the parameters:

- Volume attributes must be represented as a string (enclosed within quotations). Using an integer or boolean is not supported. In the following example, the `aetype` attribute generates an error because the value (1) is not enclosed in quotations.

```
namePrefix: "pv"
mountPrefix: "/pv"
type: "rw"
advisoryquota: "100M"
aetype: 1
```

- The following parameters are ignored because they are redundant. The CSI Driver configures these parameters automatically during volume creation:
 - `mount`
 - `quota*`
 - `createparent`
 - `path`
 - `name`

*Specifying `resources: requests: storage` in a PersistentVolumeClaim (PVC) makes it unnecessary to set the `quota` parameter. For an example, see [Example: Statically Provisioning a Volume Using the Container Storage Interface \(CSI\) Storage Plugin](#) on page 4582.

Kubernetes Access Modes

Kubernetes access modes control how a PersistentVolume (PV) is mounted on the host. [Access modes](#) can be specified on both PVs and PVCs. Only Volumes with a matching Access Mode will be bound to a PVC. The Container Storage Interface (CSI) Storage Plugin supports the following access modes for the PV and PVC spec:

- ROX (ReadOnlyMany)
- RWO (ReadWriteOnce)
- RWX (ReadWriteMany)
- RWOP (ReadWriteOncePod)*

*Supported for the latest CSI drivers (FUSE 1.2.11 and Loopback NFS 1.0.11 or later) on Kubernetes 1.29. For more information, see the [Kubernetes CSI documentation](#).

Reclaim Policy

The Kubernetes `reclaimPolicy` parameter controls what happens to a `PersistentVolume` if the corresponding `PersistentVolumeClaim` is deleted. The `Recycle` Reclaim Policy is not supported by Kubernetes CSI Drivers, so it cannot be used with the Kubernetes Interfaces for Data Fabric. You can specify the reclaim policy normally when you configure a persistent volume.

The following table shows the supported values for the reclaim policy:

Reclaim Policy Value	Description	Support
Delete (default value)	The <code>PersistentVolume</code> and the Data Fabric volume are deleted when the user deletes the corresponding <code>PersistentVolumeClaim</code> .	Supported
Retain	The <code>PersistentVolume</code> and the Data Fabric volume are not deleted when the user deletes the corresponding <code>PersistentVolumeClaim</code> .	Supported

For more information about the reclaim policy, see [Change the Reclaim Policy of a PersistentVolume](#).

Kubernetes Mount Options

The Kubernetes `mountOptions` parameter is not supported for use with the Container Storage Interface (CSI) Storage Plugin.

Configuring Static and Dynamic Provisioning Using Container Storage Interface (CSI) Storage Plugin

About this task

This page summarizes the high-level steps for configuring the Container Storage Interface (CSI) Storage Plugin after [installation](#) to provide static or dynamic provisioning. To learn more about static and dynamic provisioning, see [Static and Dynamic Volume Provisioning Using Container Storage Interface \(CSI\) Storage Plugin](#) on page 877.

Static Provisioning

Procedure

1. Create the ticket secret and deploy the secret in the Pod only if the volume is on a secure cluster. See [Configuring a Secret](#) on page 4640 for more information.
2. Configure a `PersistentVolume` in your Pod spec or as part of a separate configuration file and provide information about the volume.
See [Example: Statically Provisioning a Volume Using the Container Storage Interface \(CSI\) Storage Plugin](#) on page 4582, [Persistent Volumes](#), and [Example: Mounting a PersistentVolume for Static Provisioning](#) on page 4585.
3. Configure a `PersistentVolumeClaim` in your Pod spec or as part of a separate configuration file. See [PersistentVolumeClaims](#).
4. Run the Pod spec using `kubectl` commands.
See [Overview of kubectl](#).

Dynamic Provisioning

Procedure

1. Create the REST and ticket secrets and deploy the secrets in the Pod only if the volume is on a secure cluster.
See [Configuring a Secret](#) on page 4640 for more information.
2. Create a storage class in your Pod spec or in a separate configuration file.
See [Storage Classes](#) and [Example: Mounting a PersistentVolume for Dynamic Provisioning Using Container Storage Interface \(CSI\) Storage Plugin](#) on page 4592.
3. Configure a PersistentVolumeClaim in your Pod spec or in a separate configuration file.
See [Example: Mounting a PersistentVolume for Dynamic Provisioning Using Container Storage Interface \(CSI\) Storage Plugin](#) on page 4592.
4. Run the Pod spec using `kubectl` commands.
See [Overview of kubectl](#).

Configuring Static and Dynamic Provisioning for a Raw Block Volume

[Raw block volumes](#) are supported for both static and dynamic provisioning. To request a raw-block PersistentVolumeClaim, set `volumeMode: Block`. If not specified, `volumeMode` defaults to `Filesystem` in the PersistentVolumeClaimSpec. PersistentVolumes also have a `volumeMode` field in the PersistentVolumeSpec that is used for static provisioning. Block-type PVCs can only bind to Block-type PVs.

All the features supported on Filesystem-persistent volumes are supported on Block volumes. For example:

- Create and Delete Volumes
- Expand Volumes
- Clone Volumes
- Create and Delete Snapshot
- Snapshot Restore

Block volumes are supported only in single-node-writer access modes. At any given time, they can only be published once as read/write on a single node. For Block volumes, the CSI driver does not format the block device; it just binds the block device to the target path. The application pod can choose to format the block device to any required Linux file system, such as ext4, xfs, btrfs, and others.

Each block volume is stored in an HPE Data Fabric file. Statically provisioned block files are located at the path designated in the `volumePath` specified in the persistent volume definition. Dynamically provisioned block files are located at the path designated by the `mountPrefix` in the storage class. For fast, random block-write performance, these files should not be erasure coded (warm tiering) or tiered off to an objectstore (cold tiering).

Static Provisioning Example

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: test-blockpv
  namespace: test-csi
spec:
  accessModes:
```

```

- ReadWriteOnce
volumeMode: Block
persistentVolumeReclaimPolicy: Delete
capacity:
  storage: 5G
csi:
  driver: com.mapr.csi-kdf
  volumeHandle: test-simplepv
  volumeAttributes:
    volumePath: "/user/guest/myblockvolume"
    cluster: "clusterA"
    cldbHosts: "10.10.10.210"
    securityType: "secure"
    platinum: "true"
    capacityBytes: "5000000000"

```

NOTE: For the Loopback NFS CSI driver, change driver to `com.mapr.csi-nfskdf`.

Dynamic Provisioning Example

Note that no change in the StorageClass is required:

```

kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: test-secure-block-pvc
  namespace: test-csi
spec:
  storageClassName: test-secure-sc
  accessModes:
    - ReadWriteOnce
  volumeMode: Block
  resources:
    requests:
      storage: 5G

```

Pod Specification

In the pod specification, you must specify `volumeDevices` and `devicePath` for the block volume instead of `volumeMounts` and `mountPath`.

```

apiVersion: v1
kind: Pod
metadata:
  name: test-secure-block-pod
spec:
  containers:
    - name: fc-container
      image: fedora:26
      command: ["/bin/sh", "-c"]
      args: [ "tail -f /dev/null" ]
      volumeDevices:
        - name: data
          devicePath: /dev/xvda
  volumes:
    - name: data
      persistentVolumeClaim:
        claimName: test-secure-block-pvc

```

Configuring a Secret

Kubernetes Secrets enable you to inject sensitive data into a pod. The examples in this section show how Secrets can be used in static and dynamic provisioning. Secrets are not by themselves secure. It

is important to turn on encryption at rest for Secrets. See [Encrypting Secret Data at Rest](#). For more information about security and Secrets, see [Security Properties](#).

During installation of the driver, the Kubernetes token that was moved into the pod is written to the host node so that the plugin can query a Secret to pull the ticket for mounting. This Kubernetes token is sensitive and should be protected. The token is placed in `/var/run/secrets/kubernetes.io/serviceaccount`.

Here is an example of a configuration file for a Kubernetes Secret:

```
apiVersion: v1
kind: Secret
metadata:
  name: mapr-provisioner-secrets
  namespace: test-driver
type: Opaque
data:
  ...
```

The following table describes the fields in the sample Secret file. For more information, see [Secrets](#) in the Kubernetes documentation.

Parameter	Description
apiVersion	The Kubernetes API version.
kind	The type of object being created.
name	A string to identify the Secret.
type	The type of Secret being created. For type Opaque, clients must treat these values as opaque and pass them unmodified back to the server.

REST Secrets

For dynamic provisioning, you must use a Secret to pass the user name and password of a Data Fabric user to the provisioner. This user must have privileges to create and delete a Data Fabric volume. The credentials allow the provisioner to make REST calls to the Data Fabric webserver. Secrets are protected by the Kubernetes [RBAC](#).

The following example shows a REST secret in the Secret file:

```
apiVersion: v1
kind: Secret
metadata:
  name: mapr-provisioner-secrets
  namespace: test-driver
type: Opaque
data:
  MAPR_CLUSTER_USER: cm9vdA==
  MAPR_CLUSTER_PASSWORD: bWFwcg==
```

The following table describes the REST secret fields in the REST Secret example:

Parameter	Description
MAPR_CLUSTER_CLIENTCERT	Parameter for specifying the client certificate. You must express the parameter as a base64 representation of the client certificate. See Converting a String to Base64 on page 4642.
MAPR_CLUSTER_CLIENTKEY	Parameter for specifying the client key for the client certificate. You must express the parameter as a base64 representation of the client key. See Converting a String to Base64 on page 4642.

Parameter	Description
MAPR_CLUSTER_USER	The base64 representation of a Data Fabric user that has the ability to create and delete Data Fabric volumes. See Converting a String to Base64 on page 4642.
MAPR_CLUSTER_PASSWORD	The base64 representation of the password for the user defined by the MAPR_CLUSTER_USER parameter. See Converting a String to Base64 on page 4642.
MAPR_CLUSTER_TICKET	The base64 representation of the ticket contents generated on the Data Fabric cluster using the <code>mapr login</code> utility. For dynamic provisioning, with the latest CSI drivers, you can configure a Data Fabric ticket to authenticate to the Data Fabric webserver to make REST calls. This parameter is provided as a Beta feature.
MAPR_CLUSTER_TLSCERT	Parameter for providing the CA certificate. If MAPR_CLUSTER_TLSCERT is not specified, the CSI driver uses a nonsecure HTTP connection to the Data Fabric REST servers. You must express the parameter as a base64 representation of the TLS certificate. See Converting a String to Base64 on page 4642.

Ticket Secrets

For static and dynamic provisioning, you must specify a Secret, which is the base64 representation of the ticket, to enable the POSIX client to communicate with a secure Data Fabric cluster. The ticket for the POSIX client can be generated on the Data Fabric cluster by using the `mapr login` on page 3283 utility.

The following example shows a ticket Secret:

```
apiVersion: v1
kind: Secret
metadata:
  name: mapr-ticket-secret
  namespace: mapr-examples
type: Opaque
data:
  CONTAINER_TICKET: CHANGETHIS!
```

The following table describes the CONTAINER_TICKET field in the ticket Secret example:

Parameter	Description
CONTAINER_TICKET	Base64-encoded ticket value. See Converting a String to Base64 on page 4642.

Ticket secret specified in CONTAINER_TICKET is used to perform read/write operation on the provisioned volumes. To specify/edit ticket secret, the user must have access to volumes.

Use different types of CONTAINER_TICKET based on the conditions that follow:

- If a pod user (via Linux or LDAP user) exists on the Data Fabric cluster, and:
 - if both the ticket and pod user have same UserID and GroupID, use `service` ticket.
 - if the ticket and pod user have different UserID and GroupID, use `servicewithimpersonation` ticket.
- If the pod user does not exist in Data Fabric cluster, use `tenant` ticket of the user that exists on Data Fabric cluster (via Linux or LDAP user). Use UserID and GroupID of the pod user for all operations.

TIP: Tenant ticket user can only access the tenant volumes (passing `tenantuser` in `StorageClass`) created by the Data Fabric administrator for that user.

To create the secret:

1. Run the following command to create the Secret file:

```
kubectl create -f <secret-file-name>.yaml
```

2. Convert sensitive data, such as a user name and password, to a base64 representation.

See [Converting a String to Base64](#) on page 4642.

3. Add the base64 representation of sensitive data in the Secret file.

For more information about the format of the Secret files, see [REST Secrets](#) on page 4579 and [Ticket Secrets](#) on page 4580 earlier in this section.

4. Deploy the secret on the pod by running the following command:

```
kubectl apply -f <secret-file-name>.yaml
```

Converting a String to Base64

Sensitive data contained in a Secret must be represented in base64. Use these steps to convert such information to the base64 representation:

For example, in Linux:

```
echo -n 'mapr' | base64
```

The output shows the base64 representation of the user name mapr is bWFwcg==.

MapR tickets include a cluster name followed by a base64-encoded string. It is not sufficient to insert the base64-encoded string into a Kubernetes Secret. You must convert *both* the cluster name and string into base64 representation and then insert the result into the Secret.

The following command shows how to convert a MapR ticket to base64 representation:

```
echo -n "cluster-name <base64-encoded ticket-value>" | base64
```

For example:

```
echo -n "cluster2 PuG0lpUXuXj9ERgKCTX0qsXYPTnqRJl6/
mLWJjdVKvE5r46QS2Bh9nC+I4Rcu0GtnWUOtKBG9gp65bsZN9Kphnr/
Wp15z8D302go951CANes/
7QQLLYVP7l2B0pGR6I1zIrc3XGwI80QWT61qpsjSVZv8z05oQ5GDYQTKpttI/yAk/
uJBES1ohCz38n9HgYALLvMALVsBPtUtG+cNGc1ktUDDMR2q1EgVzdJbuYs0uHnZX3L03euKdGL4C
4MCmrV9DWiWJxwiZ1yZu69GbZJlXxqLQBlkdMoTXk=" | base64
```

```

```

NOTE: Another method for converting values to base64 is to use an Internet tool such as <https://www.base64encode.org> to encode or decode data.

Best Practices for Using Tickets

When using secure Data Fabric clusters with the Kubernetes Interfaces for Data Fabric, you must generate tickets for your containers. Here are some best practices:

- Create a different user for each container.

- To avoid frequent renewals, use long-lived user tickets or servicewithimpersonation tickets. If you refresh or update a ticket, you must restart your containers.
- If you use an impersonation ticket, it is CRITICAL that you use security contexts in the pod definitions to avoid a misbehaving container impersonating all user IDs. For restrictions that apply to the use of impersonation tickets, see [How Impersonation Works](#) on page 2215 and [maprlogin](#) on page 3283.
- Match the security context `runAsUser` : ID and `fsGroup` : group to the ID or group used to create the ticket.

Here is an example of a pod spec that specifies a security context:

```
apiVersion: v1
kind: Pod
metadata:
  name: test-secure
  namespace: mapr-examples
spec:
  securityContext:
    runAsUser: 1000
    fsGroup: 2000
```

Example: Statically Provisioning a Volume Using the Container Storage Interface (CSI) Storage Plugin

About this task

You can designate a volume for use with Kubernetes by specifying the volume parameters directly inside the `PersistentVolume` spec.

Suppose you want to get an application container up and running quickly in the HPE Data Fabric. You already have a file-system path that you want to use for the application. You only need the data accessible to read. To make this work, you must do the following:

Procedure

1. Generate a service ticket and set the `securityType` parameter in the `PersistentVolume` spec to `secure` if the volume to mount is on a secure cluster.

See [Generating a Service Ticket](#) on page 2104 for more information. For example:

```
kind: PersistentVolume
metadata:
  name: pv-securepv-test
  namespace: test-csi
spec:
  accessModes:
  ...
  csi:
  ...
  volumeAttributes:
  ...
  securityType: "secure"
```

2. If the volume to mount is on a secure cluster, configure a Ticket Secret, and include the base64-encoded contents of the ticket file in the Ticket Secret.

For more information, see [Configuring a Secret](#) on page 4640. The following table describes the properties of the Secret file:

Property	Notes
----------	-------

apiVersion	The Kubernetes API version.
kind	The type of object being created.
name	A string to identify the Secret.
namespace	The namespace in which the Secret runs.
type	The type of Secret being created. For type Opaque, clients must treat these values as opaque and pass them unmodified back to the server.
CONTAINER_TICKET	The contents of the ticket encoded in base64. If you specified secure for the securityType, you must provide the ticket. To encode the ticket, see Converting a String to Base64 on page 4642. You may remove the ticket if the cluster is not secure.

- Set the runAsUser and the fsGroup parameters in the pod spec to the UID and GID of the user that created the ticket.

For example:

```
apiVersion: v1
kind: Pod
metadata:
  name: test-pv1
  namespace: test-csi
spec:
  ...
  securityContext:
    runAsUser: 1000
    fsGroup: 2000
  ...
```

The following table lists the properties specified in the sample pod spec:

Parameter	Notes
apiVersion	The Kubernetes API version for the pod spec.
kind	The kind of object being created. For clarity, the example uses a naked pod. Generally, it is better to use a Deployment, DaemonSet, or StatefulSet for high availability (HA) and ease of upgrade.
metadata: name	The pod name.
metadata: namespace	The namespace in which the pod runs.
securityContext: runAsUser	The user ID to run the container under. This user ID must be the same as the user ID for which the ticket was generated.
securityContext: fsGroup	The group ID to run the container under. This group ID must be the same as the group ID of the user for which the ticket was generated.

- Point the volumePath in the CSI driver setting to the desired path, and fill in the cldbHosts and cluster information.

For the complete list of volume attributes, see [volume create](#) on page 2929; however, note that volume attributes like mount, quota, createparent, path, and name are ignored when provisioning a volume. For more information, see [Data Fabric Parameters for Static and Dynamic Provisioning](#) on page 4575.

For example:

FUSE

```

apiVersion: v1
kind: PersistentVolume
metadata:
  name: test-simplepv
  namespace: test-csi
spec:
  accessModes:
    - ReadWriteOnce
  persistentVolumeReclaimPolicy: Delete
  capacity:
    storage: 5Gi
  csi:
    driver: com.mapr.csi-kdf
    volumeHandle: test-simplepv
    volumeAttributes:
      volumePath: "/"
      cluster: "clusterA"
      cldbHosts: "10.10.10.210"
      securityType: "secure"
      platinum: "true"

```

Loopback NFS

```

apiVersion: v1
kind: PersistentVolume
metadata:
  name: test-simplepv
  namespace: test-csi
spec:
  accessModes:
    - ReadWriteOnce
  persistentVolumeReclaimPolicy: Delete
  capacity:
    storage: 5Gi
  csi:
    driver: com.mapr.csi-nfskdf
    volumeHandle: test-simplepv
    volumeAttributes:
      volumePath: "/"
      cluster: "clusterA"
      cldbHosts: "10.10.10.210"
      securityType: "secure"

```

The following table lists the properties shown in the sample PersistentVolume spec:

Parameter	Notes
apiVersion	The Kubernetes API version for the Pod spec.
kind	The kind of object being created.
metadata: name	The Pod name.
metadata: namespace	The namespace in which the Pod runs.
accessModes	How the PersistentVolume is mounted on the host. All modes work the same.  NOTE: The PV and PVC modes must be the same so that they can bind. For more information, see Access Modes .

<code>csi: driver</code>	The CSI Driver being used. Call it using one of these drivers: <ul style="list-style-type: none"> FUSE driver: <code>com.mapr.csi-kdf</code> Loopback NFS driver: <code>com.mapr.csi-nfskdf</code>
<code>csi: volumeHandle</code>	The existing volume name or unique volume name for static provisioning.
<code>volumePath</code>	The mount point within the filesystem. This parameter specifies an existing MapR path.
<code>cluster</code>	The cluster name.
<code>cldbHosts</code>	The DNS names or IP addresses of the CLDB hosts for the cluster. You must provide at least one CLDB host. For fault-tolerance, providing multiple CLDB hosts is recommended. To specify multiple hosts, separate each name or IP address by a space.
<code>securityType</code>	A parameter that indicates whether tickets are used or not used. If tickets are used, specify <code>secure</code> . Otherwise, specify <code>unsecure</code> .

Example: Mounting a PersistentVolume for Static Provisioning

About this task

The information on this page is valid for both FUSE POSIX and Loopback NFS plugins. Examples or tables that mention the FUSE POSIX driver (`com.mapr.csi-kdf`) are equally valid for the Loopback NFS driver (`com.mapr.csi-nfskdf`).

For static provisioning, configuring a PersistentVolume has some advantages over annotating Kubernetes volume information in a pod spec:

- The configuration file can be shared for use by multiple pod specs.
- The configuration file enables the PersistentVolume to be mounted and available even when the pod spec that references it is removed.

For example, suppose a marketing volume exists in the secure file system under the path `/Departments/Marketing`. An administrator wants to statically provision this volume and make it available to multiple users. It is critical that data access is as fast as possible. To make this work, the administrator must do the following:

Procedure

- Create a PersistentVolume (PV) (if you have already not statically provisioned a volume as described in this [example](#)) and set the following volumeAttributes:
 - `accessMode` of the PV to `ReadWriteOnce`
 - `securityType` parameter to `secure` because the volume is on a secure cluster
 - `volumePath` in the CSI driver setting to the desired path, and fill in the `cldbHosts` and `cluster` information
 - `platinum` parameter to use the POSIX platinum client or the `license` parameter to select from three POSIX clients

For example:

```
apiVersion: v1
kind: PersistentVolume
metadata:
```

```

name: test-simplepv
namespace: test-csi
labels:
  name: pv-simplepv-test
spec:
  accessModes:
  - ReadWriteOnce
  persistentVolumeReclaimPolicy: Delete
  capacity:
    storage: 5Gi
  csi:
    nodePublishSecretRef:
      name: "mapr-ticket-secret"
      namespace: "test-csi"
    driver: com.mapr.csi-kdf
    volumeHandle: test-simplepv
    volumeAttributes:
      volumePath: "/"
      cluster: "clusterA"
      cldbHosts: "10.10.102.96"
      securityType: "secure"
      platinum: "true"
      coreSiteParams: "fs.mapr.threads=4 fs.mapr.rathreads=4"

```

The preceding example specifies the high-performance Platinum POSIX license by including `platinum: "true"` in the `volumeAttributes`.

If you have a Platinum FUSE POSIX license, Release 1.0.2 and later provide another way to control the POSIX client. Instead of specifying `platinum: "true"`, you can specify `license: "<license-name>"` and select one of three POSIX licenses (Basic, Container, or Platinum). Release 1.0.2 also adds support for a `startupConfig` line that lets you pass custom startup parameters to the FUSE process. The following example shows these options:

```

apiVersion: v1
kind: PersistentVolume
metadata:
  name: test-simplepv
  namespace: test-csi
  labels:
    name: pv-simplepv-test
spec:
  accessModes:
  - ReadWriteMany
  persistentVolumeReclaimPolicy: Delete
  capacity:
    storage: 5Gi
  csi:
    nodePublishSecretRef:
      name: "mapr-ticket-secret"
      namespace: "test-csi"
    driver: com.mapr.csi-kdf
    volumeHandle: test-simplepv
    volumeAttributes:
      volumePath: "/"
      cluster: "clusterB"
      cldbHosts: "10.10.10.210"
      securityType: "secure"
      license: "container"
      startupConfig: "fuse.asyncdirect.io=1 fuse.max.background=24
fuse.auto.inval.data=1 fuse.disable.writeback=1"
      coreSiteParams: "fs.mapr.threads=4 fs.mapr.rathreads=4"

```

The following table shows the properties defined in the sample PersistentVolume:

Parameter	Notes
metadata: name	The PersistentVolume name.
metadata: namespace	The namespace in which the PersistentVolume is stored.
accessModes	<p>How the PersistentVolume is mounted on the host.</p> <p> NOTE: The accessMode is not used to set the access mode bit on the volume. The accessMode of the PV and PVC should be the same so that they can bind.</p> <p>For more information, see Kubernetes Access Modes and Access Modes.</p>
persistentVolume ReclaimPolicy	<p>Specifies what happens to the volume when it is released by its claim. The Retain value keeps the PVC around for manual cleanup. Delete deletes the PV from Kubernetes.</p> <p> NOTE: If this volume was created using dynamic provisioning, Delete causes the underlying volume to be deleted.</p> <p>For more information, see Reclaiming.</p>
capacity	Specifies how big the allocated storage should be. This value is not validated against the quota or advisory quota. It is up to the person creating the PV to specify this value accurately.
csi: nodePublishSecretRef	The Ticket Secret for the CSI driver.
nodePublishSecretRef: name	The name of the Ticket Secret that contains the ticket to use when mounting to the cluster. See Configuring a Secret on page 4640.
nodePublishSecretRef: namespace	The namespace that contains the Ticket Secret. Use the same namespace as the namespace used by the PersistentVolume.
csi: driver	The CSI driver being used. Call it by specifying driver: mapr.com/maprfs.
volumeHandle	The existing volume name or unique volume name for static provisioning.
volumePath	The mount point within the file system. This parameter specifies an existing path. For example, you can specify the root volume as "/", providing access to the entire filesystem.
cluster	The Data Fabric cluster name.
clbdbHosts	The hostname or IP addresses of the CLDB hosts for the cluster. You must provide at least one CLDB host. For fault-tolerance, providing multiple CLDB hosts is recommended. To specify multiple hosts, separate each name or IP address by a space.
securityType	A parameter that indicates whether tickets are used or not used. If tickets are used, specify secure. Otherwise, specify unsecure.
platinum	If set to platinum: "true", the POSIX client uses the platinum driver for better performance. Note that the platinum driver consumes more host resources and Platinum licenses.

license (FUSE POSIX)	<p>Release 1.0.2 and later support the license: "<license-name>" parameter in addition to the platinum: "<true false>" parameter for the FUSE POSIX plugin. The license: "<license-name>" parameter can have one of three values that control the number of host resources that are consumed:</p> <ul style="list-style-type: none"> • "container" for the Container driver (one binary, 8 threads) • "basic" for the Basic driver (one binary, 64 threads) • "platinum" for the Platinum driver (multiple binaries, each running 64 threads) <p>Note the following considerations for using the license: "<license-name>" parameter:</p> <ul style="list-style-type: none"> • To use the license: "<license-name>" parameter, you must have a Platinum license. • If you specify both the platinum: "<true false>" parameter and the license: "<license-name>" parameter, the platinum: "<true false>" parameter overrides the license: "<license-name>" parameter. • If neither the platinum: "<true false>" nor the license: parameter is specified, the container driver is implemented.
startupConfig (FUSE POSIX)	<p>Release 1.0.2 and later support specifying the startupConfig line. The startupConfig line allows you to specify FUSE configuration parameters that are passed to the fuse.conf file. For the parameters that can be passed, see Configuring the HPE Data Fabric FUSE-Based POSIX Client on page 1876.</p> <p>If no startupConfig line is specified, these default startup settings are used:</p> <pre style="background-color: #f0f0f0; padding: 10px;">"-o allow_other -o big_writes -o auto_unmount"</pre> <p>The default settings allow other users to access the mount point, enable writes larger than 4 KB, and automatically unmount the filesystem when the process is terminated.</p> <p>The following example includes some of the additional settings that must be separated by a space (shown in bold):</p> <pre style="background-color: #f0f0f0; padding: 10px;">startupConfig: "fuse.asyncdirect.io=1 fuse.max.background=24 fuse.auto.inval.data=1 fuse.disable.writeback=1"</pre> <p>The additional settings are supported starting with FUSE v1.2.15.</p>
coreSiteParams (FUSE POSIX)	<p>Allows you to supply client-related tuning parameters that are applied to each mount created by the FUSE CSI driver. This parameter applies only to the FUSE CSI driver; it is ignored by other drivers. You must provide one or more key=value pairs separated by spaces. This parameter is supported starting with FUSE v1.2.15.</p>
startupConfig (Loopback NFS)	<p>The startupConfig line allows you to specify configuration parameters that are passed to the nfsserver.conf file. For the parameters that can be passed, see nfsserver.conf on page 3376. The startupConfig values supported for Loopback NFS are all the configs supported in the nfsserver.conf file. Values must be separated by a space. If no startupConfig line is specified, these default startup settings are used:</p> <pre style="background-color: #f0f0f0; padding: 10px;">startupConfig: "NFS_HEAPSIZE=1024 DrCacheSize=1024000"</pre>
numrpcthreads	<p>Sets the number of RPC threads for the Data Fabric client. The default value is 1. The maximum value is 4. Use this option to increase throughput with FUSE basic or container licenses or with the Loopback NFS driver.</p>
trackMemory	<p>Enables memory profiling to debug memory leaks in the FUSE or Loopback NFS process. To be enabled after direction from the DF support team. The default value is false.</p>

logLevel	Sets the log level to one of the following values: error, warn, info, or debug. For the FUSE POSIX driver (com.mapr.csi-kdf), the default value is error. For the Loopback NFS driver (com.mapr.csi-nfskdf), the default value is info.
retainLogs	Retains the logs for the pod on the host machine. The default value is false.
startDelay	<p>Sets the wait time after launching the FUSE or Loopback NFS processes and before making the mount available to the application pod. The default value is 5.</p> <p> CAUTION: Setting the value below 2 to 3 seconds may affect the availability of the mount.</p>

See [Example: Statically Provisioning a Volume Using the Container Storage Interface \(CSI\) Storage Plugin](#) on page 4582 for more information.

2. Create a PersistentVolumeClaim (PVC) spec and set the accessMode of the PVC to ReadWriteOnce.

For example:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: test-simplepvc
  namespace: test-csi
spec:
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 5G
```

The following table shows the properties used in the sample PersistentVolumeClaim:

Parameter	Notes
metadata: name	The PersistentVolumeClaim name.
metadata: namespace	The namespace in which the PersistentVolumeClaim is configured.
accessMode	<p>How the requested PersistentVolume is mounted on the host.</p> <p> NOTE: The PV and PVC modes should be the same so that they can bind.</p> <p>For more information, see Kubernetes Access Modes and Access Modes.</p>

3. Generate a service ticket, and create and deploy a ticket secret on the pod (if you have already not done it as described in steps 1 and 2 of this [example](#)).
- See [maprlogin](#) on page 3283 for information on generating a ticket and [Configuring a Secret](#) on page 4640 for information on creating and deploying a ticket secret.
4. Create the pod spec and set the runAsUser and the fsGroup parameters to the UID and GID of the user that created the ticket.

For example:

```
apiVersion: v1
kind: Pod
metadata:
  name: test-pv
  namespace: test-csi
```

```

spec:
  securityContext:
    runAsUser: 1000
    fsGroup: 2000
  containers:
  - name: busybox
    image: busybox
    args:
    - sleep
    - "10000000"
    resources:
      requests:
        memory: "2Gi"
        cpu: "500m"
    volumeMounts:
    - mountPath: /mapr
      name: maprflex
  volumes:
  - name: maprflex
    persistentVolumeClaim:
      claimName: test-simplepvc

```

The following table shows the properties defined in the sample pod spec:

Parameter	Notes
apiVersion	The Kubernetes API version for the pod spec.
kind	The kind of object being created. The example uses a naked pod for clarity. Generally, it is better to use a Deployment, DaemonSet, or StatefulSet for high availability and ease of upgrade.
metadata: name	The pod name.
metadata: namespace	The namespace in which the pod runs.
securityContext: runAsUser	The user ID to run the container under. This user ID must be the same as the user ID for which the ticket was generated.
securityContext: fsGroup	The group ID to run the container under. This group ID must be the same as the group ID of the user for which the ticket was generated.
volumeMounts: mountPath	A directory inside the container that is designated as the mount path.
volumeMounts: name	A name that you assign to the Kubernetes volumeMounts resource. Matches with Volumes: name.
Volumes: name	A string to identify the name of the Kubernetes volumes resource. The value should match volumeMounts: name.
persistentVolumeClaim: claimName	The name of the PersistentVolumeClaim (PVC). For more information, see PersistentVolumeClaims .

5. Deploy the .yaml file on the pod by running the following command:

```
kubectl apply -f <filename>.yaml
```

For each Pod mount request, the POSIX client starts with the pod's hostname and new generated hostid, which is tracked on the Data Fabric cluster. You can run the `node list` on page 2570 command on the Data Fabric cluster to determine the number of POSIX clients. For example:

FUSE POSIX

```
# maprcli node list -clientonly true
clienttype      clienthealth hostname
ip              lasthb id
posixclientbasic Inactive      4f3d34fe-2007-11e9-8980-0cc47ab39644
10.10.102.94,172.17.0.1,192.168.28.0 11225 7407394893618656436

      storage: 5G

```

Example: Mounting a PersistentVolume for Dynamic Provisioning Using Container Storage Interface (CSI) Storage Plugin

About this task

This example also uses a PersistentVolume. However, unlike the previous example, when you use the dynamic provisioner, you do not need to create a PersistentVolume manually. The PersistentVolume is created automatically based on the parameters specified in the referenced StorageClass.

Dynamic provisioning is useful in cases where you do not want Data Fabric and Kubernetes cluster administrators to create storage manually to store the pod storage state.

The following example uses a PersistentVolumeClaim that references a Storage Class. In this example, a Kubernetes administrator has created a storage class called `test-secure-sc` for pod creators to use when they want to create persistent storage for their pods. In this example, it is important for the created pod storage to survive the deletion of a pod.

The information on this page is valid for both FUSE POSIX and Loopback NFS plugins. Examples or tables that mention the FUSE POSIX provisioner (`com.mapr.csi-kdf`) are equally valid for the Loopback NFS provisioner (`com.mapr.csi-nfskdf`).

To dynamically provision a volume, you must do the following:

Procedure

1. Generate a user ticket, and create and deploy a ticket secret on the pod. See:
 - [Best Practices for Using Tickets](#) on page 4643 to select the right ticket
 - [maprlogin](#) on page 3283 for information about generating a ticket
 - [Configuring a Secret](#) on page 4640 for information about creating and deploying a ticket secret
2. Create the REST secret and deploy the secret on the pod.
See [Configuring a Secret](#) on page 4640 for information about creating and deploying a ticket secret.
3. Create a StorageClass similar to the following:

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
  name: test-secure-sc
  namespace: test-csi
provisioner: com.mapr.csi-kdf
allowVolumeExpansion: true
reclaimPolicy: Delete
parameters:
  csiProvisionerSecretName: "mapr-provisioner-secrets"
  csiProvisionerSecretNamespace: "test-csi"

  fuse.auto.inval.data=1 fuse.disable.writeback=1"
  coreSiteParams: "fs.mapr.threads=4 fs.mapr.rathreads=4"
```

For more information, see [Storage Classes](#). The following table shows the properties defined in the sample StorageClass:

Property	Description
apiVersion	The Kubernetes API version for the StorageClass spec.
kind	The kind of object being created. This is a StorageClass.
metadata: name	The name of the StorageClass. Administrators should specify the name carefully because it will be used by pod authors to help select the right StorageClass for their needs.

Property	Description
metadata: namespace	The namespace in which the StorageClass runs. This namespace can be different from the namespace used by the PVC and pod, since the StorageClass namespace can be a cross-namespace resource.
provisioner	The provisioner being used. For the FUSE POSIX provisioner, specify <code>com.mapr.csi-kdf</code> . For the Loopback NFS provisioner, specify <code>com.mapr.csi-nfskdf</code> .
csiNodePublishSecret Name	The name of the Secret that contains the ticket to use when mounting to the HPE Data Fabric cluster. See Configuring a Secret on page 4640.
csiNodePublishSecret Namespace	The namespace that contains the Secret. Use the same namespace as the namespace used by the pod.
csiProvisionerSecret Name (deprecated) csi.storage.k8s.io/ provisioner-secret-name	The name of the Kubernetes Secret that is used to store Data Fabric administrative credentials (user, password, and ticket information for the Data Fabric webserver). To use the provisioner, you must configure a Secret. See Configuring a Secret on page 4640.
csiProvisionerSecret Namespace (deprecated) csi.storage.k8s.io/ provisioner-secret-namespace	The namespace for the Secret containing the Data Fabric administrative credentials (user name and password information for a Data Fabric user that has the privileges to create volumes). This namespace can be different from the namespace used by the pod, since a pod author or namespace admin might not be trusted to create administration Secrets for the Data Fabric cluster.
restServers	A space-separated list of Data Fabric webserver. Specify the hostname or IP address and port number of each REST server for the cluster. For fault tolerance, providing multiple REST server hosts is recommended.
cldbHosts	The hostname or IP addresses of the CLDB hosts for the Data Fabric cluster. You must provide at least one CLDB host. For fault-tolerance, providing multiple CLDB hosts is recommended. To specify multiple hosts, separate each name or IP address by a space.
cluster	The Data Fabric cluster name.
securityType	A parameter that indicates whether Data Fabric tickets are used or not used. If Data Fabric tickets are used, specify <code>secure</code> . Otherwise, specify <code>unsecure</code> .
namePrefix	A prefix for the Data Fabric volume to be created. For example, if you specify <code>PV</code> as the <code>namePrefix</code> , the first dynamically created volume might be named <code>PV.bevefsescr</code> . The provisioner generates random names using lower-case letters. If you do not specify a prefix, the provisioner uses <code>maprprovisioner</code> as a prefix.
mountPrefix	The parent path of the mount in the Data Fabric file system. If you do not specify a mount prefix, the provisioner mounts your volume under the Data Fabric root.  NOTE: User provisioning a volume under this <code>mountPrefix</code> requires read-write permissions to mount the newly created volume; otherwise, the volume provision will fail.
advisoryquota	The advisory storage quota for the volume. The <code>advisoryquota</code> is one of the Data Fabric parameters that you can specify for dynamic provisioning. For more information, see Before You Begin on page 4623.
trackMemory	Enables memory profiling to debug memory leaks in the FUSE or Loopback NFS process. To be enabled after direction from the DF support team. The default value is <code>false</code> .
logLevel	Sets the log level to one of the following values: <code>error</code> , <code>warn</code> , <code>info</code> , or <code>debug</code> . For the FUSE POSIX driver (<code>com.mapr.csi-kdf</code>), the default value is <code>error</code> . For the Loopback NFS driver (<code>com.mapr.csi-nfskdf</code>), the default value is <code>info</code> .

Property	Description
retainLogs	Retains the logs for the pod on the host machine. The default value is false.
startupConfig (FUSE POSIX)	<p>Release 1.0.2 and later support specifying the startupConfig line. The startupConfig line allows you to specify FUSE configuration parameters that are passed to the fuse.conf file. For the parameters that can be passed, see Configuring the HPE Data Fabric FUSE-Based POSIX Client on page 1876.</p> <p>If no startupConfig line is specified, these default startup settings are used:</p> <pre>"-o allow_other -o big_writes -o auto_unmount"</pre> <p>The default settings allow other users to access the mount point, enable writes larger than 4 KB, and automatically unmount the file system when the process is terminated.</p> <p>The following example includes some additional settings that must be separated by a space (shown in bold):</p> <pre>startupConfig: "fuse.asyncdirect.io=1 fuse.max.background=24 fuse.auto.inval.data=1 fuse.disable.writeback=1"</pre> <p>The additional settings are supported starting with FUSE v1.2.15.</p>
startupConfig (Loopback NFS)	<p>The startupConfig line allows you to specify configuration parameters that are passed to the nfsserver.conf file. For the parameters that can be passed, see nfsserver.conf on page 3376. The startupConfig values supported for Loopback NFS are all the configs supported in the nfsserver.conf file. Values must be separated by a space. If no startupConfig line is specified, these default startup settings are used:</p> <pre>startupConfig: "NFS_HEAPSIZE=1024 DrCacheSize=1024000"</pre>
numrpcthreads	Sets the number of RPC threads for the Data Fabric client. The default value is 1. The maximum value is 4. Use this option to increase throughput with FUSE basic or container licenses or with the Loopback NFS driver.
coreSiteParams (FUSE POSIX)	Allows you to supply client-related tuning parameters that are applied to each mount created by the FUSE CSI driver. This parameter applies only to the FUSE CSI driver; it is ignored by other drivers. You must provide one or more key=value pairs separated by spaces. This parameter is supported starting with FUSE v1.2.15.
startDelay	<p>Sets the wait time after launching the FUSE or Loopback NFS processes and before making the mount available to the application pod. The default value is 5.</p> <p> CAUTION: Setting the value below 2 to 3 seconds may affect the availability of the mount.</p>

4. Configure a PersistentVolumeClaim similar to the following:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: test-secure-pvc
  namespace: test-csi
spec:
  storageClassName: test-secure-sc
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 5G
```

The following table shows the properties defined in the sample PersistentVolumeClaim:

Property	Description
apiVersion	The Kubernetes API version for the pod spec.
kind	The kind of object being created. This is a PersistentVolumeClaim (PVC).
metadata: name	The PVC name.
metadata: namespace	The namespace in which the PVC runs. This should be the same namespace used by the pod.
storageClassName	The name of the storage class requested by the PersistentVolumeClaim. For more information, see Dynamic Provisioning and Storage Classes .
accessModes	How the PersistentVolume is mounted on the host. For more information, see Access Modes .
requests: storage	The storage resources being requested, or that were requested and have been allocated. The pod author can use this parameter to specify how much quota is needed for the Data Fabric volume. For the units, see Resource Model .

5. Create the pod spec similar to the following:

```
apiVersion: v1
kind: Pod
metadata:
  name: test-secure-pod
  namespace: test-csi
spec:
  containers:
    - name: busybox
      image: busybox
      args:
        - sleep
        - "1000000"
      resources:
        requests:
          memory: "2Gi"
          cpu: "500m"
      volumeMounts:
        - mountPath: /mapr
          name: maprflex
  volumes:
    - name: maprflex
      persistentVolumeClaim:
        claimName: test-secure-pvc
```

The following table shows the properties defined in the sample pod spec:

Property	Description
apiVersion	The Kubernetes API version for the pod spec.
kind	The kind of object being created. For clarity, this example uses a naked Pod. Generally, it is better to use a Deployment, DaemonSet, or StatefulSet for high availability and ease of upgrade.
metadata: name	The pod name.
metadata: namespace	The namespace in which the pod runs. It should be the same namespace in which the PVC runs.
volumeMounts: mountPath	A directory inside the container that is designated as the mount path.

Property	Description
volumeMounts: name	A name that you assign to the Kubernetes volumeMounts resource. The value should match Volumes: name.
Volumes: name	A string to identify the name of the Kubernetes volumes resource. The value should match volumeMounts: name.
persistentVolumeClaim: claimName	The name of the PersistentVolumeClaim (PVC). For more information, see PersistentVolumeClaims .

6. Deploy the .yaml file on the pod by running the following command:

```
kubectl apply -f <filename>.yaml
```

For each pod mount request, the POSIX client starts with the pod's hostname and new generated hostid, which is tracked on the Data Fabric cluster. You can run the [node list](#) on page 2570 command on the cluster to determine the number of POSIX clients. For example:

FUSE POSIX

```
# maprcli node list -clientonly true
clienttype clienthealth hostname ip lasthb id
posixclientbasic Inactive 4f3d34fe-2007-11e9-8980-0cc47ab39644

          memory: "2Gi"
          cpu: "500m"
      volumeMounts:
        - mountPath: /mapr
          name: maprflex
  volumes:
    - name: maprflex
      persistentVolumeClaim:
        claimName: test-secure-pvc

```

Example: Volume Cloning for Dynamic Provisioning

About this task

You can clone a volume from an existing volume by configuring a PersistentVolumeClaim that specifies the volume PVC as the data source. In the following example, the PVC named testcsi-secure-pvc serves as the data source for creating a new volume named testcsi-secure-pvc-clone:

```

kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: testcsi-secure-pvc-clone
  namespace: test-csi
spec:
  storageClassName: testcsi-secure-sc

```

```

accessModes:
  - ReadWriteOnce
resources:
  requests:
    storage: 10G
dataSource:
kind: PersistentVolumeClaim
name: testcsi-secure-pvc

```

When cloning extra large volumes (volumes measuring hundreds of GB), you might experience timeouts or a failure to clone the volume. To prevent timeouts with extra large volumes, increase the retry timeout setting for the `csi-provisioner` sidecar container. See the `--timeout` argument in the latest `csi-mapr-kdf-<version>.yaml`.

For more information, see [CSI Volume Cloning](#).

Example: Volume Expansion for Dynamic Provisioning Using Container Storage Interface (CSI) Storage Plugin

About this task

The following versions of the Container Storage Interface (CSI) Storage Plugin support a volume expansion feature for dynamically provisioned volumes:

- FUSE POSIX plugin versions [1.1.0](#) and later
- Loopback NFS plugin versions [1.0.0](#) and later

Volume expansion means you can increase the storage quota of volumes created by the CSI driver. Note that the `StorageClass` must have `allowVolumeExpansion` set to `true` for volume expansion to succeed. For more information about volume expansion, see [Expanding Persistent Volume Claims](#).

To use volume expansion, increase the storage value and reapply the `PersistentVolumeClaim` configuration. For example, in the following PVC configuration, to increase the storage quota for the volume from 5G to 10G, change `storage: 5G` to `storage: 10G`, and run the `kubectl apply -f <path_to_pvc>.yaml` command:

```

kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: test-secure-pvc
  namespace: test-csi
spec:
  storageClassName: test-secure-sc
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 5G

```

Verifying Creation of a Kubernetes PersistentVolumeClaim and Persistent Volume

About this task

Once the pod spec is installed, you can verify the status of a `PersistentVolumeClaim` and/or a `PersistentVolume` by using the `kubectl` command. For example:

Procedure

1. Run the Kubernetes `get` command to verify the status of the `PersistentVolumeClaim`:

NOTE: The information on this page is valid for both FUSE POSIX and Loopback NFS plugins. Examples or tables that mention the FUSE POSIX driver (`com.mapr.csi-kdf`) are equally valid for the Loopback NFS driver (`com.mapr.csi-nfskdf`).

Static Provisioning

```
# kubectl describe pvc -n test-csi
Name:          mapr-secure-claim
Namespace:     test-csi

```

3. Run the `node list` on page 2570 command on the cluster to determine the number of POSIX clients.

For each pod mount request, the POSIX client starts with the pod's hostname and new generated hostid, which is tracked on the cluster. For example:

```

# maprcli node list -clientonly true
clienttype      clienthealth  hostname
ip              lasthb      id
posixclientbasic Inactive      4f3d34fe-2007-11e9-8980-0cc47ab39644

```

Managing Snapshots Using the Container Storage Interface (CSI) Storage Plugin

This section describes how to create and delete one or more snapshots of volumes dynamically provisioned by the Container Storage Interface (CSI) Storage Plugin on the Data Fabric cluster.

The Container Storage Interface (CSI) Storage Plugin v1.x.x uses the `csi-snapshotter` to support snapshot provisioning.

CSI now supports snapshot restore, which allows you to create a new volume from the snapshot data of another volume. See [Creating a Volume from a Snapshot](#) on page 4619. To manually restore a volume, see [Copying From a Snapshot Using the CLI](#) on page 1537.

Creating a Snapshot Using the Container Storage Interface (CSI) Storage Plugin

About this task

You can create one or more snapshots of a dynamically provisioned volume using the Container Storage Interface (CSI) Storage Plugin.

Creating a Snapshot of a Dynamically Provisioned Volume on the Cluster

Procedure

1. Verify that the volume was successfully provisioned by checking the PersistentVolume (PV) and PersistentVolumeClaim (PVC) for the volume.

For example, run the `kubectl describe` command to verify the PV and then the PVC.

```
# kubectl describe pv -n test-csi
Name:                mapr-pv-e46a50cd-2012-11e9-84c0-0cc47ab39644
Labels:              <none>
Annotations:        pv.kubernetes.io/provisioned-by: com.mapr.csi-kdf
Finalizers:          [kubernetes.io/pv-protection]
StorageClass:       test-secure-sc
Status:              Bound
Claim:               test-csi/test-secure-pvc
Reclaim Policy:      Delete
Access Modes:        RWO
VolumeMode:          Filesystem
Capacity:            5Gi
Node Affinity:       <none>
Message:

3 External provisioner is provisioning volume for claim "test-csi/
test-secure-pvc"
Normal      ProvisioningSucceeded    3m40s
com.mapr.csi-kdf_csi-controller-kdf-0_69805ad1-2010-11e9-88dc-d610076b9fb
3 Successfully provisioned volume
mapr-pv-e46a50cd-2012-11e9-84c0-0cc47ab39644
Mounted By: test-secure-pod

```

2. Deploy the REST secret .yaml file by running the following command:

```
kubectl apply -f <secret filename>.yaml
```

The Secret file should look similar to the following:

```

# Copyright (c) 2009 & onwards. MapR Tech, Inc., All rights reserved
apiVersion: v1
kind: Secret
metadata:
  name: mapr-snapshot-secrets
  namespace: test-csi
type: Opaque
data:
  MAPR_CLUSTER_USER: cm9vdA==
  MAPR_CLUSTER_PASSWORD: bWFwcg==

```

For more information, see [Configuring a Secret](#) on page 4640.

3. Create a snapshot class for provisioning a snapshot of the volume. For example, the snapshot class file should look similar to the following:

FUSE

```

apiVersion: snapshot.storage.k8s.io/v1
kind: VolumeSnapshotClass
metadata:
  name: testcsi-snapshotclass
  namespace: test-csi
driver: com.mapr.csi-kdf
deletionPolicy: Delete
parameters:
  restServers: "10.10.102.95:8443"
  cluster: "mycluster"
  csi.storage.k8s.io/snapshotter-secret-name: mapr-snapshot-secrets
  csi.storage.k8s.io/snapshotter-secret-namespace: test-csi

```

Loopback NFS

```

apiVersion: snapshot.storage.k8s.io/v1
kind: VolumeSnapshotClass
metadata:
  name: testcsi-snapshotclass
  namespace: test-csi
driver: com.mapr.csi-nfskdf

```

```

deletionPolicy: Delete
parameters:
  restServers: "10.10.102.95:8443"
  cluster: "mycluster"
  csi.storage.k8s.io/snapshotter-secret-name: mapr-snapshot-secrets
  csi.storage.k8s.io/snapshotter-secret-namespace: test-csi

```

The sample snapshot class file shown above contains the following properties:

Property	Description
apiVersion	The Kubernetes API version for the StorageClass spec.
kind	The kind of object being created. This is a StorageClass.
metadata: name	The name of the snapshot class. Administrators should specify the name carefully because it will be used by Pod authors to help select the right snapshot class for their needs.
metadata: namespace	The namespace in which the snapshot class runs.
driver	The CSI volume plugin to use for provisioning the volume snapshots. For example: <code>com.mapr.csi-kdf</code> .
restServers	A space-separated list of web servers. Specify the hostname or IP address and port number of each REST server for the cluster. For fault tolerance, providing multiple REST server hosts is recommended.
cluster	The cluster name.
csiSnapshotterSecret Name (deprecated) csi.storage.k8s.io/ snapshotter-secret-n ame	The name of the Kubernetes Secret that is used to store administrative credentials (user, password, and ticket information for the webserver). To use the provisioner, you must configure a Secret. See Configuring a Secret on page 4640.
csiSnapshotterSecret Namespace (deprecated) csi.storage.k8s.io/ snapshotter-secret-n amespace	The namespace for the Secret containing the administrative credentials (user name and password information for a user that has the privileges to create volumes). This namespace can be different from the namespace used by the Pod, since a Pod author or namespace admin might not be trusted to create administration Secrets for the cluster.

4. Deploy the snapshot class by running the following command:

```
kubectl apply -f <snapshot class>.yaml
```

5. Verify whether the snapshot class was successfully deployed by running one of the following commands:

```
# kubectl get volumesnapshotclass -n test-csi
NAME                                AGE
test-snapshotclass                 41s
root@qa102-92:~/csi-kdf-3/csi-kdf/examples/snapshot# kubectl describe
volumesnapshotclass -n test-csi
Name:                             test-snapshotclass
Namespace:
Labels:                            <none>
Annotations:  kubectl.kubernetes.io/last-applied-configuration:
                {"apiVersion":"snapshot.storage.k8s.io/v1",
                {"kind":"VolumeSnapshotClass", "metadata":{"annotations":
                {}, "name":"test-snapshotclass"}, "p...
API Version:  snapshot.storage.k8s.io/v1
Kind:         VolumeSnapshotClass
Metadata:
  Creation Timestamp:  2019-01-24T21:13:35Z
  Generation:         1
  Resource Version:    1039219
  Self Link:          /apis/snapshot.storage.k8s.io/v1/
volumesnapshotclasses/test-snapshotclass
  UID:                e94a1fc8-201c-11e9-84c0-0cc47ab39644
Parameters:
  Cluster:                clusterA
  Csi Snapshotter Secret Name:  mapr-snapshot-secrets
  Csi Snapshotter Secret Namespace: test-csi
  Name Prefix:             test-snapshot
  Rest Servers:            10.10.10.210:8443
Snapshotter:              com.mapr.csi-kdf
Events:                   <none>
```

```
# kubectl get volumesnapshotclass -n test-csi -o yaml
apiVersion: v1
items:
- apiVersion: snapshot.storage.k8s.io/v1
  kind: VolumeSnapshotClass
  metadata:
    annotations:
      kubectl.kubernetes.io/last-applied-configuration: |
        {"apiVersion":"snapshot.storage.k8s.io/
v1", "kind":"VolumeSnapshotClass", "metadata":{"annotations":
{}}, "name":"test-snapshotclass"}, "parameters":
{"cluster":"clusterA", "csiSnapshotterSecretName":"mapr-snapshot-secrets",
"csiSnapshotterSecretNamespace":"test-csi", "namePrefix":"test-snapshot",
"restServers":"10.10.10.210:8443"}, "snapshotter":"com.mapr.csi-kdf"}
    creationTimestamp: "2019-01-24T21:13:35Z"
    generation: 1
    name: test-snapshotclass
    resourceVersion: "1039219"
    selfLink: /apis/snapshot.storage.k8s.io/v1/volumesnapshotclasses/
test-snapshotclass
    uid: e94a1fc8-201c-11e9-84c0-0cc47ab39644
  parameters:
    cluster: clusterA
    csiSnapshotterSecretName: mapr-snapshot-secrets
    csiSnapshotterSecretNamespace: test-csi
    namePrefix: test-snapshot
    restServers: 10.10.10.210:8443
    snapshotter: com.mapr.csi-kdf
  kind: List
```

```

metadata:
  resourceVersion: ""
  selfLink: ""

```

6. Associate the snapshot class with the PersistentVolumeClaim (for the volume to take a snapshot of) by creating a VolumeSnapshot. For example, the VolumeSnapshot file should look similar to the following:

```

apiVersion: snapshot.storage.k8s.io/v1
kind: VolumeSnapshot
metadata:
  name: testcsi-secure-snapshot
  namespace: test-csi
spec:
  volumeSnapshotClassName: testcsi-snapshotclass
  source:
    persistentVolumeClaimName: testcsi-secure-pvc

```

The sample VolumeSnapshot file shown above contains the following properties:

Property	Description
metadata: name	The VolumeSnapshot name.
metadata: namespace	The namespace in which the VolumeSnapshot runs.
snapshotClassName	The volumeSnapshotClassName.
source: name	The persistentVolumeClaimName.

7. Deploy the VolumeSnapshot by running the following command:

```
kubectl apply -f <volume snapshot>.yaml
```

8. Verify whether VolumeSnapshot was successfully deployed by doing the following:

- a) Run one of the following commands to retrieve the VolumeSnapshot:

```
# kubectl get volumesnapshot -n test-csi -o yaml
apiVersion: v1
items:
- apiVersion: snapshot.storage.k8s.io/v1
  kind: VolumeSnapshot
  metadata:
    annotations:
      kubectl.kubernetes.io/last-applied-configuration: |
        {"apiVersion":"snapshot.storage.k8s.io/
v1","kind":"VolumeSnapshot","metadata":{"annotations":
{},"name":"test-snapshot","namespace":"test-csi"},"spec":
{"snapshotClassName":"test-snapshotclass","source":
{"kind":"PersistentVolumeClaim","name":"test-secure-pvc"}}}
  creationTimestamp: "2019-01-24T21:16:21Z"
  finalizers:
  - snapshot.storage.kubernetes.io/volumesnapshot-protection
  generation: 5
  name: test-snapshot
  namespace: test-csi
  resourceVersion: "1039445"
  selfLink: /apis/snapshot.storage.k8s.io/v1/namespaces/test-csi/
volumesnapshots/test-snapshot
  uid: 4c5293bc-201d-11e9-84c0-0cc47ab39644
  spec:
    snapshotClassName: test-snapshotclass
    snapshotContentName:
snapcontent-4c5293bc-201d-11e9-84c0-0cc47ab39644
    source:
      apiGroup: null
      kind: PersistentVolumeClaim
      name: test-secure-pvc
  status:
    creationTime: "2019-01-24T21:16:22Z"
    readyToUse: true
    restoreSize: null
kind: List
metadata:
  resourceVersion: ""
  selfLink: ""
```

```
# kubectl describe volumesnapshot -n test-csi

```

9. Log in to the cluster and verify by running the [volume snapshot list](#) on page 3049 command. For example:

```

# maprcli volume snapshot list -path /csisc/
csisc-securesc-txiqvdxwu -cluster clusterA -json
{
  "timestamp":1548365090744,
  "timeofday":"2019-01-24 01:24:50.744 GMT-0800 PM",
  "status":"OK",
  "total":1,
  "data":[
    {
      "ownername":"root",
      "ownertype":"1",
      "volumeid":"234021649",
      "volumename":"csisc-securesc.txiqvdxwu",
      "volumepath":"/csisc/csisc-securesc-txiqvdxwu",
      "snapshotid":"256000051",

      "snapshotname":"mapr-snapshot-4c5293bc-201d-11e9-84c0-0cc47ab39644",
      "creationtime":"Thu Jan 24 13:16:22 PST 2019",
      "cumulativeReclaimSizeMB":"0",
      "ownedsize":"0",
      "sharedSize":"0",
      "volumeSnapshotAces":{
        "readAce":"p",
        "writeAce":"p"
      }
    }
  ]
}

```

Creating Multiple Snapshots of a Dynamically Provisioned Volume

Procedure

1. Perform steps 1 - 5 described in the [Creating a Snapshot of a Dynamically Provisioned Volume on the Cluster](#) on page 4607 section.
2. Create a VolumeSnapshot similar to the one shown in step 6 of the [Creating a Snapshot of a Dynamically Provisioned Volume on the Cluster](#) on page 4607 section for each additional snapshot to create for the volume.

For example:

```
apiVersion: snapshot.storage.k8s.io/v1
kind: VolumeSnapshot
metadata:
  name: test-snapshot1
  namespace: test-csi
spec:
  snapshotClassName: test-snapshotclass
  source:
    name: test-secure-pvc
    kind: PersistentVolumeClaim
```

3. Repeat step 7 in [Creating a Snapshot of a Dynamically Provisioned Volume on the Cluster](#) on page 4607 for each additional volume snapshots you have created.

- Log in to the cluster and verify by running the `volume snapshot list` on page 3049 command. For example:

```
# maprcli volume snapshot list -path /csisc/
csisc-securesc-txiqvdxwu -cluster clusterA -json
{
  "timestamp":1548365359138,
  "timeofday":"2019-01-24 01:29:19.138 GMT-0800 PM",
  "status":"OK",
  "total":2,
  "data":[
    {
      "ownername":"root",
      "ownertype":"1",
      "volumeid":"234021649",
      "volumename":"csisc-securesc.txiqvdxwu",
      "volumepath":"/csisc/csisc-securesc-txiqvdxwu",
      "snapshotid":"256000051",

      "snapshotname":"mapr-snapshot-4c5293bc-201d-11e9-84c0-0cc47ab39644",
      "creationtime":"Thu Jan 24 13:16:22 PST 2019",
      "cumulativeReclaimSizeMB":"0",
      "ownedsize":"0",
      "sharedSize":"0",
      "volumeSnapshotAces":{
        "readAce":"p",
        "writeAce":"p"
      }
    },
    {
      "ownername":"root",
      "ownertype":"1",
      "volumeid":"234021649",
      "volumename":"csisc-securesc.txiqvdxwu",
      "volumepath":"/csisc/csisc-securesc-txiqvdxwu",
      "snapshotid":"256000052",

      "snapshotname":"mapr-snapshot-19282d27-201f-11e9-84c0-0cc47ab39644",
      "creationtime":"Thu Jan 24 13:29:15 PST 2019",
      "cumulativeReclaimSizeMB":"0",
      "ownedsize":"0",
      "sharedSize":"0",
      "volumeSnapshotAces":{
        "readAce":"p",
        "writeAce":"p"
      }
    }
  ]
}
```

Deleting a Snapshot of a Dynamically Provisioned Volume

About this task

You can delete snapshots you created using Container Storage Interface (CSI) Storage Plugin. To delete:

Procedure

1. Run the following command:

```
kubectl delete -f <volume snapshot>.yaml
```

For example:

```
# kubectl delete -f test-snapshot1.yaml
volumesnapshot.snapshot.storage.k8s.io "test-snapshot1" deleted
```

2. Log in to the cluster and verify that the snapshot was deleted by running the [volume snapshot list](#) on page 3049 command.

For example:

```
# maprcli volume snapshot list -path /csisc/
csisc-secure-sc-txiqvdxwu -cluster clusterA -json
{
  "timestamp":1548365417772,
  "timeofday":"2019-01-24 01:30:17.772 GMT-0800 PM",
  "status":"OK",
  "total":1,
  "data":[
    {
      "ownername":"root",
      "ownertype":"1",
      "volumeid":"234021649",
      "volumename":"csisc-secure-sc-txiqvdxwu",
      "volumepath":"/csisc/csisc-secure-sc-txiqvdxwu",
      "snapshotid":"256000051",

      "snapshotname":"mapr-snapshot-4c5293bc-201d-11e9-84c0-0cc47ab39644",
      "creationtime":"Thu Jan 24 13:16:22 PST 2019",
      "cumulativeReclaimSizeMB":"0",
      "ownedsize":"0",
      "sharedSize":"0",
      "volumeSnapshotAces":{
        "readAce":"p",
        "writeAce":"p"
      }
    }
  ]
}
```

Creating a Volume from a Snapshot

You can restore a volume from a volume snapshot by configuring a PersistentVolumeClaim that specifies the volume snapshot as the data source.

In the following example, the snapshot named testcsi-secure-snapshot serves as the data source for creating a new volume named testcsi-secure-pvc-restore:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: testcsi-secure-pvc-restore
  namespace: test-csi
spec:
  storageClassName: testcsi-secure-sc
  accessModes:
```

```

- ReadWriteOnce
resources:
  requests:
    storage: 10G
dataSource:
  kind: VolumeSnapshot
  apiGroup: snapshot.storage.k8s.io
  name: testcsi-secure-snapshot

```

When creating a volume from snapshots of extra large volumes (volumes measuring hundreds of GB), you might experience timeouts or a failure to create the volume. To prevent timeouts with extra large volumes, increase the retry timeout setting of the `csi-snapshotter` sidecar container. See the `--timeout` argument in the latest `csi-maprkd-f-<version>.yaml`.

For more information, see [Persistent Volumes](#).

Enabling the Platinum POSIX Client for Container Storage Interface (CSI) Storage Plugin

When you install the Container Storage Interface (CSI) Storage Plugin, the Container FUSE-based POSIX client package is installed on the CSI Driver container. The CSI Driver also supports the use of the Basic, Container, and Platinum FUSE-based POSIX client. For a comparison of the POSIX client packages, see [Preparing for Installation \(HPE Data Fabric POSIX Client\)](#) on page 388.

NOTE: Enabling the Platinum POSIX client is not required for the Loopback NFS plug-in.

To install the Platinum POSIX client, include the `platinum` parameter in your pod spec. For example:

```

volumeAttributes:
  volumePath: "/"
  cluster: "clusterA"
  cldbHosts: "10.10.102.96"
  securityType: "secure"
  platinum: "true"

```

Release 1.0.2 and later support another method for specifying the POSIX client. You can use the `license` parameter and specify the Container, Basic, or Platinum driver. For example:

```

volumeAttributes:
  volumePath: "/"
  cluster: "clusterA"
  cldbHosts: "10.10.102.96"
  securityType: "secure"
  license: "platinum"

```

For more information, see [Example: Mounting a PersistentVolume for Static Provisioning](#) on page 4585.

Logging for the CSI Driver and Provisioner

Describes the event logs for the CSI driver and provisioner for both FUSE and Loopback NFS plugins.

Logs for the Container Storage Interface (CSI) Storage Plugin can be found in `/var/log/csi-maprkd-f/`. The following table shows the new log-file format. Before the FUSE 1.2.2 and Loopback NFS 1.0.2 drivers were introduced, the log files included a version in the file name.

Log File Type	FUSE or Loopback NFS	Log File	Description	Which Nodes
Driver events log	FUSE	<code>csi-plugin.log</code>	Captures CSI Driver events such as registering the driver and CSI Driver logs for node mount and unmount operations.	All Kubernetes nodes.
	Loopback NFS	<code>csi-nfsplugin.log</code>		

Log File Type	FUSE or Loopback NFS	Log File	Description	Which Nodes
Provisioner events log	FUSE	csi-provisioner.log	Captures provisioner events such as registering the CSI provisioner and CSI Controller events such as Create/Delete volumes, Create/Delete Snapshots etc.	The Kubernetes node where the provisioner StatefulSet pod is running.
	Loopback NFS	csi-nfsprovisioner.log		

NOTE: The directory must grant rw permissions for creating the logs and must grant write/append permissions to the plug-in and provisioner.

Troubleshooting the Container Storage Interface (CSI) Storage Plugin

This section describes how to resolve common problems you might encounter when installing and using the Container Storage Interface (CSI) Storage Plugin.

Troubleshooting CSI Driver installation

Run the following commands to display information about the pods that are deployed for the CSI plugin and provisioner:

FUSE

```
kubectl get pods -n mapr-csi
```

Loopback NFS

```
kubectl get pods -n mapr-nfscsi
```

The installation is considered successful if the `get pods` command shows the pods in the Running state. For example, your output should look similar to the following when the CSI plugin is deployed on three worker nodes:

FUSE

mapr-csi 4h25m	csi-controller-kdf-0	5/5	Running	0
mapr-csi 4h25m	csi-nodeplugin-kdf-2kfrf	3/3	Running	0
mapr-csi 4h25m	csi-nodeplugin-kdf-lq5nw	3/3	Running	0
mapr-csi 4h25m	csi-nodeplugin-kdf-pkrzt	3/3	Running	0

Loopback NFS

csi-controller-nfskdf-0	7/7	Running	0	22h
csi-nodeplugin-nfskdf-5rjt2	3/3	Running	0	18h
csi-nodeplugin-nfskdf-7d9cs	3/3	Running	0	22h
csi-nodeplugin-nfskdf-qw7kg	3/3	Running	0	22h

The preceding output shows the following:

FUSE

- `csi-nodeplugin-kdf-*`: Daemonset pods are deployed on all the Kubernetes worker nodes.
- `csi-controller-kdf-0`: A StatefulSet pod is deployed on a single Kubernetes worker node.

Loopback NFS

- `csi-nodeplugin-nfskdf-*`: Daemonset pods are deployed on all the Kubernetes worker nodes.
- `csi-controller-nfskdf-0`: A StatefulSet pod is deployed on a single Kubernetes worker node.

Troubleshoot CSI Plugin Deployment Failures

If the pods show a failure in the deployment, run the following `kubectl` commands to see the container logs:

FUSE

```
kubectl logs <csi-nodeplugin-*> -n mapr-csi -c <nodeplugin-pod-container>
```

Loopback NFS

```
kubectl logs csi-controller-nfskdf-0 -n mapr-nfscsi -c  
<controller-pod-container>
```

Here, replace `<nodeplugin-pod-container>` with the container that is failing. You can also run the following `kubectl` command to see the controller logs:

```
kubectl logs csi-controller-kdf-0 -n mapr-csi -c <controller-pod-container>
```

Here, replace `<controller-pod-container>` with the container that is failing.

Troubleshooting Volume Provisioning

To check for provisioner errors, check the provisioner log:

FUSE

```
tail -100f /var/log/csi-maprkdf/csi-provisioner.log
```

Loopback NFS

```
tail -100f /var/log/csi-maprkdf/csi-nfsprovisioner.log
```

Troubleshooting Mount Operation

Check the CSI Storage plug-in log for mount or unmount errors:

FUSE

```
tail -100f /var/log/csi-maprkdf/csi-plugin.log
```

Loopback NFS

```
tail -100f /var/log/csi-maprkdf/csi-nfsplugin.log
```

If you don't see any errors, see the kubelet logs on the node where the pod is scheduled to run. For specific errors, check the CSI Storage plugin logs.

Troubleshooting CSI Storage Plugin Discovery with kubelet

Check the kubelet path for Kubernetes deployment from the kubelet process running with `--root-dir`. The `--root-dir` is a string that contains the directory path for managing kubelet files (such as volume mounts, etc.) and defaults to `/var/lib/kubelet`. If the Kubernetes environment has a different kubelet

path, modify the CSI driver deployment .yaml file with the new path, and redeploy the CSI Storage Plugin again.

Troubleshooting Snapshot Provisioning

See the provisioner log and check for any provisioner errors:

```
tail -100f /var/log/csi-maprkdf/csi-provisioner.log
```

If there are no errors, run the following `kubectl` command to check the snapshot:

```
kubectl describe volumesnapshot.snapshot.storage.k8s.io <snapshot-name> -n <namespace-name>
```

Here:

- `<snapshot-name>`: Name of the VolumeSnapshot Object defined in yaml.
- `<namespace-name>`: Namespace where the VolumeSnapshot object is created.

Troubleshooting No Space on Disk Error

The devicemapper storage driver used for Docker allows only 10 GB by default, resulting in "no space left on device" errors when writing to new directories for a new volume mount request. If `--maxvolumespernode` is configured to be greater than 20 and the underlying Docker is using the devicemapper storage driver, do the following to increase the storage size:

1. Change the storage driver to a value other than devicemapper, which restricts container storage to 10 GB by default.
2. Increase the default container storage to more than the default of 10 GB for the devicemapper storage driver for the Docker container running on a Kubernetes worker node.

For example, do the following to increase the storage size to 50 GB:

1. In the `/etc/sysconfig/docker-storage` file, add `--storage-opt dm.basesize=50G` under `DOCKER_STORAGE_OPTIONS` section.
2. Restart Docker.
3. Run the following command to confirm that the setting is correctly applied:

```
docker info | grep "Base Device Size"
```

Kubernetes FlexVolume Driver Configuration

This section describes how to use and troubleshoot the HPE Data Fabric for Kubernetes FlexVolume Driver.

For more information about the HPE Data Fabric for Kubernetes, see [Kubernetes Interfaces for Data Fabric FlexVolume Driver Overview](#) on page 880.

Using Data Fabric for Kubernetes FlexVolume Driver

This section describes how to configure Kubernetes objects to enable persistent storage and includes example configuration files for static and dynamic provisioning.

Before You Begin

Before configuration, be sure to review the following notes about supported and unsupported features and parameters:

Data Fabric Parameters for Dynamic Provisioning

In dynamic provisioning, you can specify Data Fabric parameters for the Data Fabric volume to be created. For a list of the Data Fabric parameters that you can use, see [volume create](#) on page 2929. Note these considerations for using the Data Fabric parameters:

- Volume attributes must be represented as a string (enclosed within quotations). Using an integer or boolean is not supported. In the following example, the `aetype` attribute will generate an error because the value (1) is not enclosed in quotations.

```
namePrefix: "pv"
mountPrefix: "/pv"
type: "rw"
advisoryquota: "100M"
aetype: 1
```

- The following Data Fabric parameters are ignored because they are redundant or not supported in the Kubernetes implementation:
 - `mount`
 - `quota*`
 - `createparent`
 - `path`
 - `name`

*Specifying resources: requests: storage in a PersistentVolumeClaim (PVC) (see [Example: Mounting a PersistentVolume for Static Provisioning Using the FlexVolume Driver](#) on page 4628) makes it unnecessary to set the Data Fabric quota parameter.

Kubernetes Access Modes

Kubernetes access modes control how a PersistentVolume (PV) is mounted on the host. [Access modes](#) can be specified on both PVs and PVCs. Only Volumes with a matching Access Mode will be bound to a PVC. Unfortunately, beyond the PVC/PV binding behavior, PVs using FlexVolume drivers ignore these access modes in the current version of Kubernetes. All access modes will work with the Data Fabric for Kubernetes. However, they will appear the same. This means the ROX mode will not make the volume read only. If you want read-only behavior, specify `readOnly` in the FlexVolume driver flags.

PersistentVolumeClaim Protection

PVC protection is a Kubernetes 1.9 alpha feature that restricts the user from deleting a PVC while it is being used by an active Pod. Alpha features are not tested for use with the volume plug-in and provisioner. However, without PVC protection, you should not delete a PVC that is still attached to Pods. If you have not turned on PVC protection, ensure that you do not delete PVC's that are in use. In the current release of the Data Fabric for Kubernetes, deleting a PVC causes undefined behavior.

Reclaim Policy

The Kubernetes `reclaimPolicy` parameter controls what happens to a PersistentVolume if the corresponding PersistentVolumeClaim is deleted. The `Recycle` Reclaim Policy is not supported by Kubernetes FlexVolume Drivers, so it cannot be used with KDF. The `Retain` Policy is currently broken in Kubernetes 1.9 StoragePolicies but not in static PersistentVolumes. The Data Fabric for Kubernetes has a workaround that allows Retain policy on dynamically provisioned volumes by passing the

`reclaimPolicy`: in the parameters rather than in the standard place that FlexVolumes ignore. You can specify the reclaim policy normally when you configure a persistent volume.

The following table shows the supported values for the reclaim policy:

Reclaim Policy Value	Description	Support
Delete (default value)	The PersistentVolume and the Data Fabric volume are deleted when the user deletes the corresponding PersistentVolumeClaim.	Supported
Retain	The PersistentVolume and the Data Fabric volume are not deleted when the user deletes the corresponding PersistentVolumeClaim.	Supported*
Recycle	Performs a basic scrub on a PersistentVolume and makes it available for a new PersistentVolumeClaim.	Not Supported by Kubernetes Flexvolumes

*Not supported for dynamic provision without a workaround.

For more information about the reclaim policy, see [Change the Reclaim Policy of a PersistentVolume](#).

Kubernetes Mount Options

The Kubernetes `mountOptions` parameter is not supported for use with the Data Fabric for Kubernetes because it is not supported for use with the FlexVolume plug-in.

Steps for Configuring the Data Fabric for Kubernetes FlexVolume Driver

This page summarizes the high-level steps for configuring the Data Fabric for Kubernetes FlexVolume Driver to provide static or dynamic provisioning. To learn more about static and dynamic provisioning, see [Static and Dynamic Provisioning Using FlexVolume Driver](#) on page 882.

Static Provisioning

1. Install the Data Fabric for Kubernetes.

See [Installing the Data Fabric for Kubernetes FlexVolume Driver](#) on page 349.

2. In your Pod spec or as part of a separate configuration file, configure a PersistentVolume.

See [Example: Mounting a PersistentVolume for Static Provisioning Using the FlexVolume Driver](#) on page 4628 and [Persistent Volumes](#).

3. Do *one* of the following:

- Annotate the Pod spec to provide information about the Data Fabric volume.

See [Example: Statically Provisioning a Data Fabric Volume Using the FlexVolume Plug-in](#) on page 4626.

- In your Pod spec or as part of a separate configuration file, configure a PersistentVolumeClaim.

See [PersistentVolumeClaims](#).

4. Run the Pod spec by using `kubectl` commands. See [Overview of kubectl](#).

Dynamic Provisioning

1. Install the Data Fabric for Kubernetes.

See [Installing the Data Fabric for Kubernetes FlexVolume Driver](#) on page 349.

2. In your Pod spec or in a separate configuration file, create a storage class.
See [Example: Mounting a PersistentVolume for Dynamic Provisioning Using the FlexVolume Driver](#) on page 4632 and [Storage Classes](#).
3. In your Pod spec or in a separate configuration file, configure a PersistentVolumeClaim.
See [Example: Mounting a PersistentVolume for Dynamic Provisioning Using the FlexVolume Driver](#) on page 4632.
4. Run the Pod spec by using `kubectl` commands. See [Overview of kubectl](#).

Example: Statically Provisioning a Data Fabric Volume Using the FlexVolume Plug-in

You can designate a Data Fabric volume for use with Kubernetes by specifying the Data Fabric FlexVolume parameters directly inside the Pod spec. In the Pod spec, you define a Kubernetes volume and add the Data Fabric FlexVolume information to it. You can supply path information by using the `volumePath` parameter. The Kubernetes volume is only as persistent as the Pod. By defining the volume this way, when the Pod is removed, the Kubernetes volume is also immediately unmounted and removed. This approach to static provisioning is most appropriate when you want to get up and running quickly or when you want the Pod and Kubernetes volume lifecycle to be the same.

For example, a developer wants to get her application container up and running quickly with Data Fabric. She already has a Data Fabric path that she wants to use for the application. She only needs the data accessible to read. To make this work, she must:

1. Generate a Data Fabric service ticket, and set the `securityType` parameter in the Pod spec to `secure`. See [Generating a Service Ticket](#) on page 2104.
2. Configure a Ticket Secret, and include the base64-encoded contents of the ticket file in the Ticket Secret. See [Configuring a Secret](#) on page 4640.
3. Set the `runAsUser` and the `fsGroup` parameters to the UID and GID of the user that created the ticket.
4. Point the `volumePath` in the `flexVolume` setting to the desired path, and fill in the `clusterHosts` and `cluster` information.

NOTE: The following example works for on-premise deployments. For GKE and AWS deployments, you must set a default StorageClass to the `maprfs` StorageClass. If a default StorageClass is not provided for GKE and AWS deployments, the volume is created using your default StorageClass, which might not be a good fit. For information about changing the default StorageClass, see [Change the default StorageClass](#).

```
apiVersion: v1

            ticketSecretNamespace: "mapr-examples"
  ---
apiVersion: v1
kind: Secret
metadata:
  name: mapr-ticket-secret
  namespace: mapr-examples
type: Opaque
data:
  CONTAINER_TICKET: <BASE64 ENCODED VERSION OF CONTENTS OF TICKET FILE>

```

The following tables describe the parameters in the example:

Pod

Parameter	Notes
apiVersion	The Kubernetes API version for the Pod spec.
kind	The kind of object being created. For clarity, the example uses a naked Pod. Generally, it is better to use a Deployment, DaemonSet, or StatefulSet for high availability (HA) and ease of upgrade.
metadata: name	The Pod name.
metadata: namespace	The namespace in which the Pod runs.
securityContext: runAsUser	The user ID to run the container under. This user ID must be the same as the user ID for which the ticket was generated.
securityContext: fsGroup	The group ID to run the container under. This group ID must be the same as the group ID of the user for which the ticket was generated.
volumeMounts: mountPath	A directory inside the container that is designated as the mount path.
volumeMounts: name	A name that you assign to the Kubernetes volumeMounts resource. Matches with Volumes: name.
Volumes: name	A string to identify the name of the Kubernetes volumes resource. Matches with volumeMounts: name.
flexVolume: driver	The Data Fabric FlexVolume driver being used. Call it using this driver: mapr.com/maprfs.

flexVolume: readOnly	Specifies that the FlexVolume driver should tell the Data Fabric POSIX Client to mount the volume with the read-only flag.
volumePath	The mount point within the Data Fabric file system. This parameter specifies an existing Data Fabric path. For example, you can specify the root volume as "/", providing access to the entire filesystem.
cluster	The Data Fabric cluster name.
cldbHosts	The DNS names or IP addresses of the CLDB hosts for the Data Fabric cluster. You must provide at least one CLDB host. For fault-tolerance, providing multiple CLDB hosts is recommended. To specify multiple hosts, separate each name or IP address by a space.
securityType	A parameter that indicates whether Data Fabric tickets are used or not used. If Data Fabric tickets are used, specify secure. Otherwise, specify unsecure.
ticketSecretName	The name of the Secret that contains the ticket to use when mounting to the Data Fabric cluster. See Configuring a Secret on page 4640.
ticketSecretNamespace	The namespace that contains the Secret. See Configuring a Secret on page 4640

Secret

Parameter	Notes
apiVersion	The Kubernetes API version.
kind	The type of object being created.
name	A string to identify the Secret.
namespace	The namespace in which the Secret runs.
type	The type of Secret being created. For type Opaque, clients must treat these values as opaque and pass them unmodified back to the server.
CONTAINER_TICKET	The contents of the Data Fabric ticket encoded in base64. If you specified secure for the securityType, you must provide the ticket. To encode the ticket, see Converting a String to Base64 on page 4642. You may remove the ticket if the Data Fabric cluster is not secure.

Example: Mounting a PersistentVolume for Static Provisioning Using the FlexVolume Driver

For static provisioning, configuring a PersistentVolume has some advantages over annotating Kubernetes volume information in a Pod spec:

- The configuration file can be shared for use by multiple Pod specs.
- The configuration file enables the PersistentVolume to be mounted and available even when the Pod spec that references it is removed.

For example: A marketing volume exists in the Data Fabric file system under the path /Departments/Marketing. An administrator wants to statically provision this volume and make it available to multiple users. It is critical that data access is as fast as possible. To make this work, the administrator must:

1. Create a PersistentVolume (PV).
2. Set the AccessMode of the PV to ReadWriteOnce.

3. Create a PersistentVolumeClaim (PVC) spec.
4. Set the AccessMode of the PVC to ReadWriteOnce.
5. Create the Pod spec.
6. Generate a Data Fabric service ticket, and set the flexVolume securityType parameter to secure. For information about generating a service ticket, see [Generating a Service Ticket](#) on page 2104.
7. Configure a Ticket Secret, and include the base64-encoded contents of the ticket file in the Ticket Secret. See [Configuring a Secret](#) on page 4640.
8. Set the runAsUser and the fsGroup parameters to the UID and GID of the user that created the ticket.
9. Set the platinum parameter in the Pod spec to platinum: "true". See [Enabling the Platinum Posix Client for Kubernetes Interfaces for Data Fabric FlexVolume Driver](#) on page 4639.
10. Point the volumePath in the flexVolume setting to the desired Data Fabric path.
11. Fill in the cldbHosts and cluster information.

```

apiVersion: v1

PersistentVolume (PV)

Parameter	Notes
Capacity	Specifies how big the allocated storage should be. This value is not validated against the Data Fabric quota or advisory quota. It is up to the person creating the PV to specify this value accurately.
accessModes	How the PersistentVolume is mounted on the host. It's important that the PV and PVC modes are the same so that they can bind. For more information, see Kubernetes Access Modes and Access Modes .
persistentVolumeReclaimPolicy	Specifies what happens to the volume when it is released by its claim. The <code>Retain</code> value keeps the PVC around for manual cleanup. <code>Delete</code> deletes the PV from Kubernetes.  NOTE: If this volume was created using dynamic provisioning, <code>Delete</code> causes the underlying volume to be deleted. <code>Recycle</code> is not supported by Kubernetes FlexVolumes. For more information, see Reclaiming .
claimRef	Specifies a default PVC to bind to. If unspecified, the PV selected for a PVC is randomly allocated based on the access mode and provides at least as much storage capacity as requested by the PVC.
flexVolume: driver	The Data Fabric FlexVolume driver being used. Call it by specifying <code>driver: mapr.com/maprfs</code> .

platinum	If set to platinum: "true", the POSIX client uses the platinum driver for better performance. Note that the platinum driver consumes more host resources and Data Fabric Platinum licenses.
cluster	The Data Fabric cluster name.
cldbHosts	The hostname or IP addresses of the CLDB hosts for the Data Fabric cluster. You must provide at least one CLDB host. For fault-tolerance, providing multiple CLDB hosts is recommended. To specify multiple hosts, separate each name or IP address by a space.
volumePath	The mount point within the Data Fabric file system. This parameter specifies an existing Data Fabric path. For example, you can specify the root volume as "/", providing access to the entire filesystem.
securityType	A parameter that indicates whether Data Fabric tickets are used or not used. If Data Fabric tickets are used, specify secure. Otherwise, specify unsecure.
ticketSecretName	The name of the Ticket Secret that contains the ticket to use when mounting to the Data Fabric cluster. See Configuring a Secret on page 4640.
ticketSecretNamespace	The namespace that contains the Ticket Secret. Use the same namespace as the namespace used by the Pod.

Pod

Parameter	Notes
apiVersion	The Kubernetes API version for the Pod spec.
kind	The kind of object being created. The example uses a naked Pod for clarity. Generally, it is better to use a Deployment, DaemonSet, or StatefulSet for high availability and ease of upgrade.
metadata: name	The Pod name.
metadata: namespace	The namespace in which the Pod runs.
volumeMounts: mountPath	A directory inside the container that is designated as the mount path.
volumeMounts: name	A name that you assign to the Kubernetes volumeMounts resource. This value should match Volumes: name.
Volumes: name	A string to identify the name of the Kubernetes volumes resource. This value should match volumeMounts: name.

PersistentVolumeClaim (PVC)

Parameter	Notes
AccessMode	How the requested PersistentVolume is mounted on the host. It's important that the PV and PVC modes are the same so that they can bind. For more information, see Kubernetes Access Modes and Access Modes .

Secret

Parameter	Notes
metadata: name	The name of the Ticket Secret. See Configuring a Secret on page 4640
metadata: namespace	The namespace in which the Ticket Secret runs.
CONTAINER_TICKET	The contents of the Data Fabric ticket encoded in base64. If you specified secure for the securityType, you must provide the ticket. To encode the ticket, see Converting a String to Base64 on page 4642. You may remove the ticket if the Data Fabric cluster is not secure.

Example: Mounting a PersistentVolume for Dynamic Provisioning Using the FlexVolume Driver

This example also uses a PersistentVolume. However, unlike the previous example, when you use the Data Fabric dynamic provisioner, you do not need to create a PersistentVolume manually. The PersistentVolume is created automatically based on the parameters specified in the referenced StorageClass.

Dynamic provisioning is useful in cases where you do not want Data Fabric and Kubernetes administrators to create storage manually to store the Pod storage state.

The following example uses a PersistentVolumeClaim that references a Storage Class. In this example, a Kubernetes Administrator has created a storage class called secure-maprfs for Pod creators to use when they want to create persistent storage for their Pods. In this example, it is important for the created Pod storage to survive the deletion of a Pod.

```

apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
  name: secure-maprfs
  namespace: mapr-examples
provisioner: mapr.com/maprfs
parameters:
  restServers: "rest1:8443"
  cldbHosts: "cldb1 cldb2 cldb3"
  cluster: "mysecurecluster"
  securityType: "secure"
  ticketSecretName: "mapr-ticket-secret"
  ticketSecretNamespace: "mapr-examples"
  maprSecretName: "mapr-provisioner-secrets"
  maprSecretNamespace: "mapr-examples"
  namePrefix: "pv"
  mountPrefix: "/pv"
  readOnly: "true"
  reclaimPolicy: "Retain"
  advisoryquota: "100M"
  readonly: "1"

---

kind: Pod
apiVersion: v1

  namespace: mapr-examples
type: Opaque
data:
  CONTAINER_TICKET: <BASE64 ENCODED VERSION OF CONTENTS OF TICKET FILE>

```

The following tables describe the parameters in the example:

StorageClass

Parameter	Notes
apiVersion	The Kubernetes API version for the StorageClass spec.
kind	The kind of object being created. This is a StorageClass.
metadata: name	The name of the StorageClass. Administrators should specify the name carefully because it will be used by Pod authors to help select the right StorageClass for their needs.

Parameter	Notes
metadata: namespace	The namespace in which the StorageClass runs. This namespace can be different from the namespace used by the PVC and Pod, since the StorageClass namespace can be a cross-namespace resource.
provisioner	The provisioner being used. for the Data Fabric provisioner, specify <code>mapr.com/maprfs</code> .
restServers	A space-separated list of Data Fabric webserver. Specify the hostname or IP address and port number of each REST server for the Data Fabric cluster. For fault tolerance, providing multiple REST server hosts is recommended.
cldbHosts	The hostname or IP addresses of the CLDB hosts for the Data Fabric cluster. You must provide at least one CLDB host. For fault-tolerance, providing multiple CLDB hosts is recommended. To specify multiple hosts, separate each name or IP address by a space.
cluster	The Data Fabric cluster name.
securityType	A parameter that indicates whether Data Fabric tickets are used or not used. If Data Fabric tickets are used, specify <code>secure</code> . Otherwise, specify <code>unsecure</code> .
ticketSecretName	The name of the Secret that contains the ticket to use when mounting to the Data Fabric cluster. See Configuring a Secret on page 4640.
ticketSecretNamespace	The namespace that contains the Secret. Use the same namespace as the namespace used by the Pod.
maprSecretName	The name of the Kubernetes Secret that is used to store Data Fabric administrative credentials (user, password, and ticket information for the Data Fabric webserver). To use the provisioner, you must configure a Secret. See Configuring a Secret on page 4640.
maprSecretNamespace	The namespace for the Secret containing the Data Fabric administrative credentials (user name and password information for a Data Fabric user that has the privileges to create Data Fabric volumes). This namespace can be different from the namespace used by the Pod, since a Pod author or namespace admin might not be trusted to create administration Secrets for the Data Fabric cluster.
namePrefix	A prefix for the Data Fabric volume to be created. For example, if you specify <code>PV</code> as the <code>namePrefix</code> , the first dynamically created volume might be named <code>PV.bevefsesr</code> . The provisioner generates random names using lower-case letters. If you do not specify a prefix, the provisioner uses <code>maprprovisioner</code> as a prefix.
mountPrefix	The parent path of the mount in Data Fabric file system. If you do not specify a mount prefix, the provisioner mounts your volume under the Data Fabric root.
readOnly	This parameter specifies that the POSIX driver should mount the Data Fabric path as read only. This is different from the <code>readonly</code> parameter for volume creation that creates the volume as read only.

Parameter	Notes
reclaimPolicy	Kubernetes does not currently support passing a non-delete reclaim policy to the StorageClass. This parameter allows you to specify <code>Retain</code> . This ensures that provisioned volumes are not automatically deleted when their calling Pods are deleted. If you specify <code>Retain</code> , you must clean up your provisioned volumes manually.
advisoryquota	The advisory storage quota for the Data Fabric volume. <code>advisoryquota</code> is one of the Data Fabric parameters that you can specify for dynamic provisioning. For more information, see Before You Begin on page 4623.
readonly	When the value is 1, this parameter specifies that the Data Fabric volume should be created as read-only. This is different from the <code>readOnly</code> parameter that mounts the Data Fabric path as read only.

Pod

Parameter	Notes
apiVersion	The Kubernetes API version for the Pod spec.
kind	The kind of object being created. For clarity, this example uses a naked Pod. Generally, it is better to use a Deployment, DaemonSet, or StatefulSet for high availability and ease of upgrade.
metadata: name	The Pod name.
metadata: namespace	The namespace in which the Pod runs. It should be the same namespace in which the PVC runs.
volumeMounts: mountPath	A directory inside the container that is designated as the mount path.
volumeMounts: name	A name that you assign to the Kubernetes <code>volumeMounts</code> resource. The value should match <code>Volumes: name</code> .
Volumes: name	A string to identify the name of the Kubernetes <code>volumes</code> resource. The value should match <code>volumeMounts: name</code> .
persistentVolumeClaim: claimName	The name of the PersistentVolumeClaim (PVC). For more information, see PersistentVolumeClaims .

PVC

Parameter	Notes
apiVersion	The Kubernetes API version for the Pod spec.
kind	The kind of object being created. This is a PersistentVolumeClaim (PVC).
metadata: name	The PVC name.
metadata: namespace	The namespace in which the PVC runs. This should be the same namespace used by the Pod.

Parameter	Notes
accessModes	How the PersistentVolume is mounted on the host. (This is a limitation of the FlexVolume driver.) For more information, see Access Modes .
storageClassName	The name of the storage class requested by the PersistentVolumeClaim. For more information, see Dynamic Provisioning and Storage Classes .
requests: storage	The storage resources being requested, or that were requested and have been allocated. The Pod author can use this parameter to tell Data Fabric how much quota is needed for the Data Fabric volume. For the units, see Resource Model .

Provisioner Secret

In the mapr-provisioner-secrets Secret:

Parameter	Notes
MAPR_CLUSTER_USER	This is the base64-encoded user ID used to log in to the Data Fabric REST server and create or delete volumes. See Converting a String to Base64 on page 4642. For more information about Secrets, see Secrets .
MAPR_CLUSTER_PASSWORD	This is the base64-encoded password for the MAPR_CLUSTER_USER. See Converting a String to Base64 on page 4642. For more information about Secrets, see Secrets .

Ticket Secret

In the mapr-ticket-secret Secret:

Parameter	Notes
CONTAINER_TICKET	The contents of the Data Fabric ticket encoded in base64. If you specified secure for the securityType, you must provide the ticket. To encode the ticket, see Converting a String to Base64 on page 4642. You may remove the ticket if the Data Fabric cluster is not secure. For more information about Secrets, see Secrets .

Identifying the Data Fabric Volume Created During Dynamic Provisioning

Describes how to find the name of the Data Fabric volume created during dynamic provisioning.

In dynamic provisioning, the provisioner creates a new Data Fabric volume with a name that is randomly generated using lower-case letters. For example, if you specify PV as the namePrefix in the StorageClass, the first dynamically created volume might be named PV.bevefsesqr. If you do not specify a prefix, the provisioner uses maprprovisioner as a prefix.

To find the name of the new Data Fabric volume and the path to the volume:

1. Use the `kubectl describe` command to get information about the PVC:

```
kubectl describe pvc -n <namespace> <pvc-name>
```

The command output shows the name of the PersistentVolume (PV) that was created: For example:

```
kubectl describe pvc -n mapr-examples maprfs-secure-pvc109
Name:          maprfs-secure-pvc109
Namespace:     mapr-examples
StorageClass:  secure-maprfs
Status:        Bound
Volume:     pv-ikmqxfwtjh
Labels:        <none>
Annotations:   control-plane.alpha.kubernetes.io/
leader={holderIdentity:"ed60e649-0c68-11e8-acd5-36117e0e7e02", "leaseDurationSeconds":15, "acquireTime":"2018-02-09T22:09:43Z"
              pv.kubernetes.io/bind-competed=yes
              pv.kubernetes.io/bound-by-controller=yes
              volume.beta.kubernetes.io/storage-provisioner=mapr.com/
maprfs
Finalizers:    []
Capacity:      300M
Access Modes:  RWO
Events:
```

2. Use the `kubectl get` command and the PersistentVolume (PV) name to obtain a description of the PersistentVolume:

```
kubectl get pv <pv-name> -o yaml
```

The command output shows the path to the Data Fabric volume. For example:

```
kubectl get pv pv-ikmqxfwtjh -o yaml
apiVersion: v1
kind: PersistentVolume
metadata:
  annotations:
    mapr.com/description: 'Dynamically provisioned PV for MapR-FS:
pv.ikmqxfwtjh'
    mapr.com/maprProvisionerIdentity: mapr.com/maprfs
    mapr.com/provisionerVersion: v1.0.0
    mapr.com/restServers: 10.10.88.214:8443
    mapr.com/secretName: mapr-provisioner-secrets
    mapr.com/secretNamespace: mapr-examples
    mapr.com/volumeName: pv.ikmqxfwtjh
    pv.kubernetes.io/provisioned-by: mapr.com/maprfs
  creationTimestamp: 2018-02-09T22:21:22Z
  name: pv-ikmqxfwtjh
  resourceVersion: "2875820"
  selfLink: /api/v1/persistentvolumes/pv-ikmqxfwtjh
  uid: 8f11aa11-0de7-11e8-bdd6-84a9c4fbf7cb
spec:
  accessModes:
    - ReadWriteOnce
  capacity:
    storage: 300M
  claimRef:
    apiVersion: v1
    kind: PersistentVolumeClaim
    name: maprfs-secure-pvc109
    namespace: mapr-examples
    resourceVersion: "2842548"
    uid: ce5555e4-0de5-11e8-bdd6-84a9c4fbf7cb
  flexVolume:
    driver: mapr.com/maprfs
    options:
      clldbHosts: xx.xx.xx.xxx yy.yy.yy.yyy zz.zz.zz.zzz
      cluster: Test5
      mountOptions: ""
      platinum: "true"
      readOnly: "false"
      securityType: secure
      ticketSecretName: mapr-ticket-secret
      ticketSecretNamespace: mapr-examples
      volumePath: /pv/pv-ikmqxfwtjh
  persistentVolumeReclaimPolicy: Delete
  storageClassName: secure-maprfs
status:
  phase: Bound
```

Creating a Default StorageClass

As noted in [Example: Statically Provisioning a Data Fabric Volume Using the FlexVolume Plug-in](#) on page 4626, some deployments can require a default StorageClass. A default StorageClass can reduce the effort it takes to create Pods. For example, you could use a default StorageClass to provision storage dynamically to a Data Fabric location for any PersistentVolumeClaim that you create.

If you set the `DefaultStorageClass` admission controller (see [PodSecurityPolicy](#)), and you wish to enable a Data Fabric StorageClass as the default, follow the instructions in [Change the default StorageClass](#).

Verifying Creation of a Kubernetes PersistentVolumeClaim and Persistent Volume

Once the Pod spec is installed, you can verify the status of a `PersistentVolumeClaim` or a `PersistentVolume` by using the Kubernetes `get` command. For example:

```
$ kubectl get pvc
NAME          STATUS    VOLUME          CAPACITY   ACCESS MODES   STORAGECLASS   AGE
maprfs-pvc    Bound     pv-rsojpoapxy    8Mi        RWO             simple-maprfs   3d
$ kubectl get pv
NAME          CAPACITY   ACCESS MODES   RECLAIM POLICY   STATUS
CLAIM
Pv-rsojpoapxy 8Mi        RWO             Delete            Bound    mapr-demo/
maprfs-pvc
```

For an example of creating a `PersistentVolumeClaim` and a `PersistentVolume`, see [Example: Mounting a PersistentVolume for Static Provisioning Using the FlexVolume Driver](#) on page 4628.

Enabling the Platinum Posix Client for Kubernetes Interfaces for Data Fabric FlexVolume Driver

When you install the Kubernetes Interfaces for Data Fabric FlexVolume Driver, the Basic FUSE-based POSIX client package is installed on all nodes by default. The FlexVolume Driver also supports the use of the Platinum FUSE-based POSIX client. For a comparison of the two POSIX client packages, see [Preparing for Installation \(HPE Data Fabric POSIX Client\)](#) on page 388.

To install the Platinum POSIX client, include the `platinum` parameter in your Pod spec. For example:

```
options:
cluster: "cluster2"
platinum: "true"
cldbHosts: "10.10.102.96"
```

Mounting a Read-Only Volume

This page describes how to specify a volume that should be mounted as read-only.

The following example specifies a volume that should be mounted as read-only in a Data Fabric path or `PersistentVolume` during static provisioning:

```
flexVolume:
  driver: "mapr.com/maprfs"
  readOnly: true
  options:
    volumePath: "/path/to/data/in/mapr"
    cluster: "mycluster"
    cldbHosts: "cldb1 cldb2 cldb3"
    securityType: "secure"
    ticketSecretName: "mapr-ticket-secret"
    ticketSecretNamespace: "mapr-examples"
```

The following example shows how to specify that the volume should be mounted read-only in a `StorageClass` for dynamic provisioning. The example specifies that the POSIX driver should mount the Data Fabric path as read only. This is different from the `readOnly` parameter for volume creation that creates the volume as `readOnly`.

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
```

```

name: secure-maprfs
namespace: mapr-examples
provisioner: mapr.com/maprfs
parameters:
  restServers: "rest1:8443"
  cldbHosts: "cldb1 cldb2 cldb3"
  cluster: "mysecurecluster"
  securityType: "secure"
  ticketSecretName: "mapr-ticket-secret"
  ticketSecretNamespace: "mapr-examples"
  maprSecretName: "mapr-provisioner-secrets"
  maprSecretNamespace: "mapr-examples"
  namePrefix: "pv"
  mountPrefix: "/pv"
  readOnly: "true"
  reclaimPolicy: "Retain"
  advisoryquota: "100M"

```

The following example specifies that the volume should be created as `readOnly` in a `StorageClass` for dynamic provisioning:

```

apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
  name: secure-maprfs
  namespace: mapr-examples
provisioner: mapr.com/maprfs
parameters:
  restServers: "rest1:8443"
  cldbHosts: "cldb1 cldb2 cldb3"
  cluster: "mysecurecluster"
  securityType: "secure"
  ticketSecretName: "mapr-ticket-secret"
  ticketSecretNamespace: "mapr-examples"
  maprSecretName: "mapr-provisioner-secrets"
  maprSecretNamespace: "mapr-examples"
  namePrefix: "pv"
  mountPrefix: "/pv"
  reclaimPolicy: "Retain"
  advisoryquota: "100M"
  readOnly: "1"

```

Configuring a Secret

Kubernetes Secrets enable you to inject sensitive data into a pod. The examples in this section show how Secrets can be used in static and dynamic provisioning. Secrets are not by themselves secure. It is important to turn on encryption at rest for Secrets. See [Encrypting Secret Data at Rest](#). For more information about security and Secrets, see [Security Properties](#).

During installation of the driver, the Kubernetes token that was moved into the pod is written to the host node so that the plugin can query a Secret to pull the ticket for mounting. This Kubernetes token is sensitive and should be protected. The token is placed in `/var/run/secrets/kubernetes.io/serviceaccount`.

Here is an example of a configuration file for a Kubernetes Secret:

```

apiVersion: v1
kind: Secret
metadata:
  name: mapr-provisioner-secrets
  namespace: test-driver
type: Opaque

```

```
data:
  ...
```

The following table describes the fields in the sample Secret file. For more information, see [Secrets](#) in the Kubernetes documentation.

Parameter	Description
apiVersion	The Kubernetes API version.
kind	The type of object being created.
name	A string to identify the Secret.
type	The type of Secret being created. For type Opaque, clients must treat these values as opaque and pass them unmodified back to the server.

REST Secrets

For dynamic provisioning, you must use a Secret to pass the user name and password of a Data Fabric user to the provisioner. This user must have privileges to create and delete a Data Fabric volume. The credentials allow the provisioner to make REST calls to the Data Fabric webserver. Secrets are protected by the Kubernetes [RBAC](#).

The following example shows a REST secret in the Secret file:

```
apiVersion: v1
kind: Secret
metadata:
  name: mapr-provisioner-secrets
  namespace: test-driver
type: Opaque
data:
  MAPR_CLUSTER_USER: cm9vdA==
  MAPR_CLUSTER_PASSWORD: bWFwcg==
```

The following table describes the REST secret fields in the REST Secret example:

Parameter	Description
MAPR_CLUSTER_CLIENTCERT	Parameter for specifying the client certificate. You must express the parameter as a base64 representation of the client certificate. See Converting a String to Base64 on page 4642.
MAPR_CLUSTER_CLIENTKEY	Parameter for specifying the client key for the client certificate. You must express the parameter as a base64 representation of the client key. See Converting a String to Base64 on page 4642.
MAPR_CLUSTER_USER	The base64 representation of a Data Fabric user that has the ability to create and delete Data Fabric volumes. See Converting a String to Base64 on page 4642.
MAPR_CLUSTER_PASSWORD	The base64 representation of the password for the user defined by the MAPR_CLUSTER_USER parameter. See Converting a String to Base64 on page 4642.
MAPR_CLUSTER_TICKET	The base64 representation of the ticket contents generated on the Data Fabric cluster using the mapr login utility. For dynamic provisioning, with the latest CSI drivers, you can configure a Data Fabric ticket to authenticate to the Data Fabric webserver to make REST calls. This parameter is provided as a Beta feature.
MAPR_CLUSTER_TLSCERT	Parameter for providing the CA certificate. If MAPR_CLUSTER_TLSCERT is not specified, the CSI driver uses a nonsecure HTTP connection to the Data Fabric REST servers. You must express the parameter as a base64 representation of the TLS certificate. See Converting a String to Base64 on page 4642.

Ticket Secrets

For static and dynamic provisioning, you must specify a Secret, which is the base64 representation of the ticket, to enable the POSIX client to communicate with a secure Data Fabric cluster. The ticket for the POSIX client can be generated on the Data Fabric cluster by using the [mapr login](#) on page 3283 utility.

The following example shows a ticket Secret:

```
apiVersion: v1
kind: Secret
metadata:
  name: mapr-ticket-secret
  namespace: mapr-examples
type: Opaque
data:
  CONTAINER_TICKET: CHANGETHIS!
```

The following table describes the CONTAINER_TICKET field in the ticket Secret example:

Parameter	Description
CONTAINER_TICKET	Base64-encoded ticket value. See Converting a String to Base64 on page 4642.

Ticket secret specified in CONTAINER_TICKET is used to perform read/write operation on the provisioned volumes. To specify/edit ticket secret, the user must have access to volumes.

Use different types of CONTAINER_TICKET based on the conditions that follow:

- If a pod user (via Linux or LDAP user) exists on the Data Fabric cluster, and:
 - if both the ticket and pod user have same UserID and GroupID, use service ticket.
 - if the ticket and pod user have different UserID and GroupID, use **servicewithimpersonation** ticket.
- If the pod user does not exist in Data Fabric cluster, use tenant ticket of the user that exists on Data Fabric cluster (via Linux or LDAP user). Use UserID and GroupID of the pod user for all operations.

TIP: Tenant ticket user can only access the tenant volumes (passing tenantuser in StorageClass) created by the Data Fabric administrator for that user.

To create the secret:

1. Run the following command to create the Secret file:

```
kubectl create -f <secret-file-name>.yaml
```

2. Convert sensitive data, such as a user name and password, to a base64 representation.
See [Converting a String to Base64](#) on page 4642.

3. Add the base64 representation of sensitive data in the Secret file.

For more information about the format of the Secret files, see [REST Secrets](#) on page 4641 and [Ticket Secrets](#) on page 4642 earlier in this section.

4. Deploy the secret on the pod by running the following command:

```
kubectl apply -f <secret-file-name>.yaml
```

Converting a String to Base64

Sensitive data contained in a Secret must be represented in base64. Use these steps to convert such information to the base64 representation:

For example, in Linux:

```
echo -n 'mapr' | base64
```

The output shows the base64 representation of the user name mapr is bWFwcg==.

MapR tickets include a cluster name followed by a base64-encoded string. It is not sufficient to insert the base64-encoded string into a Kubernetes Secret. You must convert *both* the cluster name and string into base64 representation and then insert the result into the Secret.

The following command shows how to convert a MapR ticket to base64 representation:

```
echo -n "cluster-name <base64-encoded ticket-value>" | base64
```

For example:

```
echo -n "cluster2 PuG0lpuPXuDxj9ERgKCTX0qsXYPTnqRJl6/
m1WJjdVKvE5r46QS2Bh9nC+I4Rcu0GtnWRU0tKBG9gp65bsZN9Kphnr/
Wp15z8D302go951CANes/
7QQllyVP7l2B0pGR6I1zIrc3XGwI80QWT61qpsjSVZv8z05oQ5GDYQTKPtI/yAk/
uJBES1ohCz38n9HgYALLvMALVsBPTUtG+cNGc1ktUDDMR2q1EgVzdJbuYsOuHnZX3L03euKDG14C
4MCmrv9DWiWJxwiZ1yZu69GbZJlXxqLQbLkdMoTXk=" | base64

Y2x1c3RlcjIgdWVHMgxdVBYdUR4ajlfUmdLQ1RYT3FzWFlQVG5xUkpsNi9tbFdKamRWS3ZFNXI0
NlFTMkJoOW5DK0k0Umn1MEd0bldSVU90S0JHOWdwNjVic1p0OUtwaG5yL1dwMTV6OEQzTzJnbzk1
MUNBTmVzLzdRUWxsWVZQN2wyQk9wR1I2STF6SXJDM1hHd0k4T1FXVDYxcXBzaLNWwnY4ek81b1E1
R0RZUVRRUHR0SS95QwsvdUpCRVMxb2hDejM4bjlIZ1lBTEx2TUFMVnNCUHRVdEcY05HYzFrdfVE
RE1SMnExRwdWemRKYnVZc091SG5aWDMNTzNldUtER2w0QzRNQ21ydjLEV2LXSnh3aVoxeVp1NjLH
YlpKbFh4cUxPUUJsa2RNb1RYaz0K
```

NOTE: Another method for converting values to base64 is to use an Internet tool such as <https://www.base64encode.org> to encode or decode data.

Best Practices for Using Tickets

When using secure Data Fabric clusters with the Kubernetes Interfaces for Data Fabric, you must generate tickets for your containers. Here are some best practices:

- Create a different user for each container.
- To avoid frequent renewals, use long-lived user tickets or servicewithimpersonation tickets. If you refresh or update a ticket, you must restart your containers.
- If you use an impersonation ticket, it is CRITICAL that you use security contexts in the pod definitions to avoid a misbehaving container impersonating all user IDs. For restrictions that apply to the use of impersonation tickets, see [How Impersonation Works](#) on page 2215 and [maprlogin](#) on page 3283.
- Match the security context runAsUser : ID and fsGroup : group to the ID or group used to create the ticket.

Here is an example of a pod spec that specifies a security context:

```
apiVersion: v1
kind: Pod
metadata:
  name: test-secure
  namespace: mapr-examples
spec:
  securityContext:
```

```
runAsUser: 1000
fsGroup: 2000
```

Troubleshooting the Kubernetes Interfaces for Data Fabric FlexVolume Driver

This section describes how to resolve common problems you might encounter when using the Kubernetes Interfaces for Data Fabric FlexVolume driver.

Shared Memory Lock Causes POSIX Failure

Problem	On an upgrade from a previous version of the volume plug-in, POSIX can fail with the following error in the POSIX log file: Create/Attach to stats shared memory failed.
Possible Cause	A shared-memory segment lock can prevent the mount from becoming available to the requested pod.
Resolution	Follow the steps in Troubleshooting loopbacknfs POSIX Client Upgrades on page 491 to remove the lock. Then retry the operation.

Unable to Access file system

Problem	Storage is not mounted and no errors are generated in the plugin or provisioner logs .
Possible Cause	The fusermount symlink might be broken.
Resolution	If the symlink points to a location other than /opt/mapr/k8s/bin/fusermount, unlink it using the following command from the command line on the host:

```
unlink /bin/fusermount
```

Then re-create the Kubernetes Pod.

Pod Container Stuck in Container Creation State During Installation

Problem	During installation, the Pod container can become stuck in the container creation state on a node, and the /opt/mapr/k8s directory is not created. As a result, the plug-in does not get copied to the node.
Possible Cause	Unknown.
Resolution	Check the installation logs for an indication that the installation is not completed or the /opt/mapr/k8s directory is not created. Restart the kubelet service in the node:

```
systemctl restart kubelet
```

Logs for the Data Fabric for Kubernetes FlexVolume Driver

Logs for the Data Fabric for Kubernetes can be found in:

```
/opt/mapr/logs
```

Log File	Description	Which Nodes
install-k8s-plugin.log	Captures events related to the copying of files from the plug-in container to each Kubernetes host node.	All Kubernetes nodes.
plugin-k8s.log	Captures events from the FlexVolume plug-in.	All Kubernetes nodes.  NOTE: In Azure deployments, this log is hidden in the container. See Azure AKS Considerations on page 353.
provisioner-k8s.log	Captures events from the provisioner.	The Kubernetes node where the provisioner Pod is running.

Useful Troubleshooting Commands

The following Kubernetes commands can help you gather information about the resources used by Data Fabric for Kubernetes:

- `kubectl describe <resourcetype> <resource> -n <namespace>`
- `kubectl get <resourcetype> <resource> -n <namespace> -o yaml`
- `kubectl logs <pod-name> -n <namespace>`
- `journalctl -u kubelet -r` (on the relevant node)

kubectl describe command

In this example, the `kubectl describe` command displays information about the `mapr-kdfprovisioner-5dff68656-ln6vh` Pod. Note that the `kubectl describe` output includes an event section.

```
kubectl describe pod mapr-kdfprovisioner-5dff68656-ln6vh -n mapr-system
Name:          mapr-kdfprovisioner-5dff68656-ln6vh
Namespace:     mapr-system
Node:          qa101-139/10.10.101.139
Start Time:    Fri, 09 Feb 2018 12:58:36 -0800
Labels:        app=mapr-kdfprovisioner
               pod-template-hash=189924212
Annotations:   openshift.ix/scc-maprkdf-scc
Status:        Running
IP:            172.17.0.3
.             .
.             .
.             .
Node-Selectors: <none>
Tolerations:    <none>
Events:
  Type     Reason                  Age    From                      Message
  ----     -
  Normal   Scheduled               8m     default-scheduler         Successfully
assigned mapr-kdfprovisioner-5dff68656-ln6vh to qa101-139
  Normal   SuccessfulMountVolume   8m     kubelet, qa101-139        MountVolume,SetUp
succeeded for volume "logs"
  Normal   SuccessfulMountVolume   8m     kubelet, qa101-139        MountVolume,SetUp
succeeded for volume "timezone"
  Normal   SuccessfulMountVolume   8m     kubelet, qa101-139        MountVolume,SetUp
```

```

succeeded for volume "maprkdf-token-drqtt"
Normal Pulling      8m kubelet, qa101-139 pulling image
"maprtech/kdf-provisioner:1.0.0.006_centos7"
Normal Pulled       8m kubelet, qa101-139 Successfully
pulled image "maprtech/kdf-provisioner:1.0.0.006_centos7"
Normal Created      8m kubelet, qa101-139 Created container
Normal Started      8m kubelet, qa101-139 Started container

```

kubectl get command

In this example, the `kubectl get` returns the `.yaml` parameters for the `test-secure-provisioner86` Pod:

```

kubectl get pods test-secure-provisioner86 -n mapr-examples -o yaml
apiVersion: v1
kind: Pod
metadata:
  creationTimestamp: 2018-02-09T00:42:06Z
  name: test-secure-provisioner86
  namespace: mapr-examples
  resourceVersion: "721689"
  selfLink: /api/v1/namespaces/mapr-examples/pods/test-secure-provisioner86
  uid: 0dd21274-0d32-11e8-bdd6-84a9c4fbf7cb
spec:
  containers:
  - args:
    - sleep
    - "10000000"
    image: busybox
    imagePullPolicy: Always
    name: busybox
    resources: {}
    terminationMessagePath: /dev/termination-log
    terminationMessagePolicy: file
    volumeMounts:
    - mountPath: /dynvolume
      name: maprfs-pvc
    - mountPath: /var/run/secrets/kubernetes.io/serviceaccount
      name: default-token-zpv69
      readOnly: true
  dnsPolicy: ClusterFirst
  nodeName: qa108-165.qa.lab
  restartPolicy: Never
  schedulerName: default-scheduler
  securityContext: {}
  serviceAccount: default
  serviceAccountName: default
  terminationGracePeriodSeconds: 30
  tolerations:
  - effect: NoExecute
    key: node.kubernetes.io/not-ready
    operator: Exists
    tolerationSeconds: 300
  - effect: NoExecute
    key: node.kubernetes.io/unreachable
    operator: Exists
    tolerationSeconds: 300
  volumes:
  - name: maprfs-pvc

```

Running the `kubectl get` command without the `-o yaml` parameter generates less output:

```
kubectl get pods test-secure-provisioner86 -n mapr-examples
NAME                                READY    STATUS    RESTARTS    AGE
test-secure-provisioner86          1/1      Running   0            14m
```

kubectl logs command

In this example, the `kubectl logs` command returns logged output for the `mapr-kdfprovisioner-5dff68656-ln6vh` Pod:

```
kubectl logs mapr-kdfprovisioner-5dff68656-ln6vh -n mapr-system
I0209 12:58:39.956822    1 controller.go:407] Starting provisioner
controller 013d58b3-0ddc-11e8-b0dd-0242ac10003!
```

journalctl -u command

In this example, the `journalctl` command returns events for the kubelet service for the node:

```
journalctl -u kubelet -r
-- Logs begin at Thu 2017-12-28 06:24:47 PST, end at Thu 2018-02-08
17:01:49 PST. --

Ecosystem Components

The following sections provide information about each open-source project that is supported by the HPE Data Fabric.

This section contains documentation for each open-source project. You can learn how to configure, use, and integrate each project within the context of a Data Fabric cluster.

Documentation Covers All Component Versions

Unless noted, the ecosystem-component information in this content hierarchy applies to all component versions included in DEP or EEPs that are supported on the core software. For a list of the supported DEPs or EEPs, see [Ecosystem Pack Support and Lifecycle Status](#) on page 7664. For deprecated and discontinued components, see [Discontinued Ecosystem Components](#) on page 7702.

Ecosystem Packs

An Ecosystem Pack (EEP) provides a set of ecosystem components that work together on one or more Data Fabric cluster versions. Each EEP contains only one version of an ecosystem component. For example, each EEP supports only one version of Hive and one version of Spark.

HPE creates a new EEP version when a new ecosystem component is available or a patch is applied to an ecosystem component that is already in a released EEP.

A single version of core can support multiple EEPs, but only one at a time. For detailed information about each EEP, see [Data Fabric Ecosystem Pack \(DEP\) Reference](#) on page 8276. For a list of currently supported EEPs, see [Ecosystem Pack Support and Lifecycle Status](#) on page 7664.

Hadoop Ecosystem and Monitoring Components

Hadoop ecosystem components within an DEP or EEP undergo extensive interoperability testing to validate that the components can work together. Examples of Hadoop ecosystem components include Hive, Pig, Spark, and Oozie.

NOTE: Developer previews for fast-moving ecosystem components continue to be available in addition to DEP or EEPs. However, developer preview releases of ecosystem components are not tested for production environments, and they do not undergo the same interoperability testing.

For more information, see the [Data Fabric Ecosystem Pack Release Notes](#) on page 7766.

Apache Airflow

This topic provides an overview of Apache Airflow on HPE Data Fabric.

Starting from EEP 8.1.0, HPE Data Fabric supports Apache Airflow on core 6.2.x and core 7.0.0.

You can use Airflow to author, schedule, or monitor workflows or data pipelines.

The following image shows the Apache Airflow workflow:

A workflow is a Directed Acyclic Graph (DAG) of tasks used to handle big data processing pipelines. The workflows are started on a schedule or triggered by an event. DAGs define the order to run the tasks or rerun in case of failures. The tasks define the actions to be performed, like ingest, monitor, report, and others.

Airflow Architecture

The following image shows the Apache Airflow Architecture:

Airflow Components

Airflow consists of the following components:

Scheduler	Triggers the scheduled workflows and submits the tasks to an executor to run.
Executor	Executes the tasks or delegates the tasks to workers for execution.
Worker	Executes the tasks.
Web Server	Provides a user interface to analyze, schedule, monitor, and visualize the tasks and DAG. The Web Server enables you to manage users, roles, and set configuration options.
DAG Directory	Contains DAG files read by Scheduler, Executor, and Web Server.
Metadata Database	Stores the metadata about DAGs' state, runs, and Airflow configuration options.

To learn more about Airflow, see [Airflow Concepts](#).

Starting, Stopping, and Restarting Airflow Services

This topic describes how to start, stop, and restart Airflow services on HPE Data Fabric.

About this task

The Warden daemon starts the Airflow server (`airflow-dag-processor`, `airflow-api-server` and `airflow-scheduler`) automatically at installation time.

You can start and stop Airflow from the command line or from the Control System. You can use the `maprcli node services` command to start Airflow on multiple nodes at one time.

Perform the following steps to start or stop or restart Airflow from the command line:

Procedure

1. Make a list of nodes on which Airflow is configured.
2. Run the `maprcli node services` command with either `start`, `restart`, or `stop`, and specify the nodes on which Airflow is configured, separated by spaces.

```
maprcli node services -name airflow-dag-processor -action stop -nodes
<nodes list>
maprcli node services -name airflow-api-server -action stop -nodes
<nodes list>
```

```
maprcli node services -name airflow-scheduler -action stop -nodes <nodes
list>
```

Considerations for Using Airflow CLI Commands

Describes security considerations for using Airflow CLI commands.

NOTE: Starting with DEP 10.1.0 (Data Fabric 8.1.0), the Airflow CLI commands have been updated to align with the official Apache Airflow naming conventions. The following changes apply:

- `airflow-admin` & `airflow` — The previous `airflow-admin` command is now `airflow`. Use this command for Airflow server administration tasks.
- `airflow` & `airflowctl` — The previous `airflow` command has been renamed to `airflowctl`, reflecting that Airflow CTL is now distributed as a separate package (`airflowctl`).

These changes ensure that examples and instructions from the [official Apache Airflow documentation](#) can be used as-is, without modification.

For EEP 9.2.2 and later, Airflow 2.8.3 has four types of security options related to the use of Airflow CLI commands. In `opt/mapr/airflow/airflow-<version>/conf/airflow.cfg` file, you can set one of the following four options:

Option 1: This is default option. When `admin_only_cli_access = false` and `admin_cli_with_impersonation = false`:

- Only users with Data Fabric tickets can use Airflow CLI commands.
- If a user that has no ticket issues a CLI command, the command line returns an error. For example:

```
$ airflow users create --username mapr1 --firstname mapr1 --lastname
mapr1 -p mapr1 --role Admin --email admin3@example.org
Traceback (most recent call last):
  File "/opt/mapr/airflow/airflow-2.6.1/bin/airflow", line 8, in <module>
    sys.exit(main())
  File "/opt/mapr/airflow/airflow-2.6.1/build/env/lib/python3.9/
site-packages/airflow/__main__.py", line 45, in main
    resp = security_client.start("maprsasl")[2]
  File "/opt/mapr/airflow/airflow-2.6.1/build/env/lib/python3.9/
site-packages/airflow/security/maprsasl.py", line 73, in start
    return True, mechanism, self.get_init_response()
  File "/opt/mapr/airflow/airflow-2.6.1/build/env/lib/python3.9/
site-packages/airflow/security/maprsasl.py", line 55, in get_init_response
    server_key_bytes =
maprsecurity.GetTicketAndKeyForClusterInternal(MAPR_CLUSTER_NAME, 1)
SystemError: <built-in function GetTicketAndKeyForClusterInternal>
returned NULL without setting an error
```

- Only the cluster administrator (typically the mapr user) can issue commands related to Airflow users. For example, only the cluster admin can issue the `airflow users list` command or create the admin user role. An exception is generated if a non-cluster-admin user issues a command such as `airflow users list`. For example:

```
$ airflow users list
Traceback (most recent call last):
  File "/opt/mapr/airflow/airflow-2.6.1/bin/airflow", line 8, in <module>
    sys.exit(main())
    .....
    .....
  File "/opt/mapr/airflow/airflow-2.6.1/build/env/lib/python3.9/
site-packages/airflow/cli/commands/user_command.py", line 38, in <module>
    class UserSchema(Schema):
      File "/opt/mapr/airflow/airflow-2.6.1/build/env/lib/python3.9/
site-packages/airflow/cli/commands/user_command.py", line 42, in
UserSchema
    raise Exception("Only admin cluster user can manage Airflow users
list")
Exception: Only admin cluster user can manage Airflow users list
```

Option 2: When `admin_only_cli_access = true` and `admin_cli_with_impersonation = false`:

- Only cluster administrator can access ALL Airflow CLI commands.
- Impersonation is disabled.

Option 3: When `admin_only_cli_access = false` and `admin_cli_with_impersonation = true`:

- Cluster administrator can access ALL Airflow CLI commands.
- Users with Data Fabric tickets have access only to the **Airflow Task** command.
- Impersonation is enabled.

Configuring a Remote Database for Airflow

This topic describes how to configure a remote database for Airflow on the HPE Data Fabric.

About this task

Airflow uses SQLAlchemy to connect to the metadata database. The metadata database stores the information about Airflow configurations, user information, roles and policies, and statistics of each DAG state, run, and task.

You can configure databases supported by SQLAlchemy to host Airflow metadata. The most common databases are:

1. Postgres
2. MySQL
3. SQLite

While SQLite is the default database on Apache Airflow, the Airflow community recommends Postgres for most use cases. For more details, see [Set up a Database Backend](#).

For a list of the supported databases, see [Choosing database backend](#).

NOTE: Starting with DEP 10.1.0 (Data Fabric 8.1.0), the Airflow CLI commands have been updated to align with the official Apache Airflow naming conventions. The following changes apply:

- `airflow-admin` & `airflow` — The previous `airflow-admin` command is now `airflow`. Use this command for Airflow server administration tasks.
- `airflow` & `airflowctl` — The previous `airflow` command has been renamed to `airflowctl`, reflecting that Airflow CTL is now distributed as a separate package (`airflowctl`).

These changes ensure that examples and instructions from the [official Apache Airflow documentation](#) can be used as-is, without modification.

Procedure

1. Configure the remote database for Airflow. See [Set up a Database Backend](#).
2. Update `<AIRFLOW-HOME>/conf/airflow.cfg` with your SQLAlchemy connection string.
 - For PostgreSQL, update `<AIRFLOW-HOME>/conf/airflow.cfg` with:
`postgresql+psycopg2://<user>:<password>@<host>/<db>`
 - For MySQL, update `<AIRFLOW-HOME>/conf/airflow.cfg` with:
`mysql+mysqldb://<airflow-user>:<airflow-password>@<host>[:<port>]/<airflow-dbname>`
3. Create the database schema using the steps that apply to the currently installed Ecosystem Pack. To identify the Ecosystem Pack that is installed, see [Checking the EEP Version](#) on page 7530:
 - For DEP 10.1.0 and later, use the `airflow` command.

- a. Run the `airflow db migrate` command to initialize the database:

```
airflow db migrate
```

- b. Run the `airflow connections create-default-connections` command to create default connections:

```
airflow connections create-default-connections
```

4. After the database configuration completes, create a user by following the steps in the [Command Line Interface and Environment Variables Reference](#).

For example, for DEP 10.1.0 or later, use the `airflow` command:

```
airflow users create --username mapr --firstname mapr --lastname mapr -p mapr --role Admin --email admin@example.org
```

- Restart Airflow services as described in [Starting, Stopping, and Restarting Airflow Services](#) on page 4649.

Configuring SSL Security for Airflow

This topic describes the security configurations for Airflow on HPE Data Fabric.

Airflow enables SSL by default on secure clusters and you can manually configure SSL for nonsecure clusters in HPE Data Fabric.

Enabling SSL on Secure Clusters

Airflow enables SSL by default on secure clusters and uses the standard Data Fabric SSL configuration.

Enabling SSL on Nonsecure Clusters

To enable SSL on non-secure clusters, provide a certificate and a key to the webserver.

Add the following configuration options at `<airflow_home>/conf/airflow.cfg`.

```
[webserver]
web_server_ssl_cert = <path to certificate>
web_server_ssl_key = <path to private key>
```

Once you enable the SSL, you must use `https://` in the browser for secure connection.

Configuring MapR-SASL and SSL for Hooks Connections

This topic describes configuration options for MapR-SASL and SSL for hook connections in Airflow.

Using Airflow, you can import and export data to multiple systems. Airflow provides a high-level interface called Hooks to connect to these systems by integrating with Connections.

A connection is an object that stores credentials such as your username, password and hostname, the type of system you are connecting to, and other configuration options.

HPE Data Fabric 7.0.0 supports MapR-SASL authentication for Airflow.

To support MapR-SASL authentication for HPE Data Fabric 6.2.x, see [Applying a Patch](#) on page 431.

Airflow authenticates with MapR-SASL in the following ways:

Using the Ecosystem Component Client

To authenticate with MapR-SASL, Airflow uses the clients of ecosystem component installed on the node. To submit the tasks, configure a Data Fabric User Ticket on a secure cluster. See [Generating a HPE Data Fabric User Ticket](#) on page 2103.

Using the REST API or Thrift protocol

To authenticate with MapR-SASL, you can use REST API or Thrift protocol by setting the additional configuration options.

WebEZFSHook (webezfs_default connection id)

To connect with file system, set the following configuration options on extra section of connection configuration.

MapR-SASL: Set `{"auth": "maprsasl"}`.

SSL: On secure clusters, set `{"use_ssl": "true"}` option. For nondefault SSL configuration, set `{"cert": "/path_to_truststore.pem"}`.

EzHiveCliHook (hive_cli_default connection_id, auth authenticationMethod)

To connect with Hive, set the following configuration options on connection configuration.

MapR-SASL: Set {"use_beeline": true, "ssl": "true"}. Add auth parameter to EzHiveCliHook. For example: hive = EzHiveCliHook(auth="maprsasl").

EzHiveMetastoreHook (metastore_default connection id)

To connect with Hive Metastore, set the following configuration options on extra section of connection configuration.

MapR-SASL: Set {"authMechanism": "MAPRSASL"}.

EzHiveServer2Hook (hiveserver2_default connection id)

To connect with HiveServer2, set the following configuration options on extra section of connection configuration.

MapR-SASL: Set {"authMechanism": "MAPRSASL"}.

SSL: On secure clusters, set {"ssl": "true"} option. For nondefault SSL configuration, set {"certificate": "/path_to_truststore.pem"}.

EzLivyHook (livy_default connection id)

To connect with Livy, set the following configuration options on extra section of connection configuration.

MapR-SASL: Set {"auth": "maprsasl"}.

SSL: On secure clusters, set {"use_ssl": "true"} option. For nondefault SSL configuration, set {"cert": "/path_to_truststore.pem"}.

EzS3Hook (aws_default connection id)

To connect with S3, set the following configuration options on the extra section of connection configuration.

SSL: On secure clusters, set the {"cert": "/path_to_truststore.pem"} option for nondefault SSL configuration.

To connect with the HPE Data Fabric Object Store and AWS, you must also add the endpoint URL to the extra section of the connection configuration. For example:

```
{"endpoint_url": "https://<hostname>:9000"}
```

Mapping Keycloak Roles to Airflow

This topic describes the mapping of Keycloak roles to Airflow roles.

The configuration of SSO authorization for Airflow happens automatically.

If SSO configuration is already available on a Data Fabric cluster, then Airflow's roles and Data Fabric's roles get mapped as follow:

Data Fabric Roles	Air Flow Roles
fabric-manager	Admin
infrastructure-admin	Op
developer	User

Roles other than that are mentioned above can be mapped manually as follows:

Mapping of Keycloak Roles to Airflow

You need to first configure the roles in Keycloak, and then map it to Airflow roles. For details on adding new role in Keycloak see [Adding New Users to Keycloak](#) on page 1294.

To map the roles, do the steps that follow:

1. Map the role created in Keycloak to AUTH_ROLES_MAPPING variable in <airflow_home>/conf/webserver_config.py file.
2. If the default SSO configuration was changed or disabled do one of the following:
 - Run the configure.sh script **WITHOUT -R** option. For details, see [configure.sh](#) on page 3186.
 - Or
 - Change the settings manually in <airflow_home>/conf/webserver_config.py file.
3. Restarts the Airflow web server.

Manual Disabling of SSO at Airflow

To manually disable SSO and changes the authentication to AUTH_DB, do the step that follow:

1. Change the following parameters in <airflow_home>/conf/webserver_config.py as follows:
 - AUTH_TYPE = AUTH_DB
 - AUTH_USER_REGISTRATION=False
 - Comment out the line with LOGOUT_REDIRECT_URL.
2. Restart the Airflow web server.

Airflow Providers

This topic describes the Apache Airflow Provider packages available in HPE Data Fabric.

Providers contains operators, hooks, sensors, and transfer operators that enhances the core Airflow scheduling capabilities. To learn more about Providers, see [Airflow Providers](#).

Airflow provides an interface to Ecosystem Pack components, databases, and filesystem by using the providers.

The classes on Providers package in HPE Data Fabric are located inside airflow.providers.ezmeral Python package.

The following topics describes interfaces on Airflow Providers in HPE Data Fabric.

Interface to HPE Data Fabric Database

Airflow provides an interface to HPE Data Fabric Database by using the Providers.

See Provider examples of HPE Data Fabric Database at <airflow_home>/build/env/lib/python3.9/site-packages/airflow/providers/ezmeral/database/example_dags/.

Hooks

BinaryDbCliHook

Python path:

airflow.providers.ezmeral.database.hooks.binary_shell

Description: This hook is a wrapper around the hbase shell command that must have hbase binary in the PATH.

JsonDbCliHook

Python path:

airflow.providers.ezmeral.database.hooks.json_shell

EzTableHook

Description: This hook is a wrapper around the `mapr dbshell` command.

Python path:
`airflow.providers.ezmeral.database.hooks.table`

Description: This hook is a wrapper around the `maprc li table` command.

Operators**BinaryDbCliOperator**

Python path:
`airflow.providers.ezmeral.database.operators.binary_s hell`

Description: Executes HPE Data Fabric Database Binary `hbase shell` command.

JsonDbCliOperator

Python path:
`airflow.providers.ezmeral.database.operators.json_s he ll`

Description: Executes HPE Data Fabric Database Binary `mapr dbshell` command.

CreateEzTableOperator

Python path:
`airflow.providers.ezmeral.database.operators.table`

Description: Creates HPE Data Fabric Database table.

DropEzTableOperator

Python path:
`airflow.providers.ezmeral.database.operators.table`

Description: Drops HPE Data Fabric Database table.

ImportJsonEzTableOperator

Python path:
`airflow.providers.ezmeral.database.operators.table`

Description: Imports HPE Data Fabric Database JSON table.

ExportJsonEzTableOperator

Python path:
`airflow.providers.ezmeral.database.operators.table`

Description: Exports HPE Data Fabric Database JSON table.

ImportBinaryEzTableOperator

Python path:
`airflow.providers.ezmeral.database.operators.table`

Description: Imports HPE Data Fabric Database Binary table.

ExportBinaryEzTableOperator

Python path:
`airflow.providers.ezmeral.database.operators.table`

Description: Exports HPE Data Fabric Database Binary table.

Sensors**EzTableSensor**

Python path:
`airflow.providers.ezmeral.database.sensors.table`

Description: Waits for the table to show up in HPE Data Fabric Database.

Interface to the File System

Airflow provides an interface to the file system by using the Providers.

See Provider examples of the file system at <airflow_home>/build/env/lib/python3.9/site-packages/airflow/providers/ezmeral/fs/example_dag/.

Hooks

EZFSHook

Python path:

airflow.providers.ezmeral.fs.hooks.ezfs.EZFSHook

Description: Interacts with file system.

API::class

airflow.providers.ezmeral.fs.hooks.ezfs.EZFSHook(classpath: list = '/opt/mapr/lib/*')

The *classpath* parameter provides a path for Java and binaries libraries to access the file system Java client.

WebEZFSHook

Python path:

airflow.providers.ezmeral.fs.hooks.web_ezfs.WebEZFSHook

Description: Interacts with file system through HttpFS.

API: The same API as [Apache Web HDFS](#).

Sensors

EzfsSensor

Python path:

airflow.providers.ezmeral.fs.sensors.ezfs.EzfsSensor

Description: Waits for a file or folder to show up in the file system.

API: The same API as [Apache HDFS Sensor](#).

EzfsRegexSensor

Python path:

airflow.providers.ezmeral.fs.sensors.ezfs.EzfsRegexSensor

Description: Waits for matching files by matching on regex.

API: The same API as [Apache HDFS Regex sensor](#).

EzfsFolderSensor

Python path:

airflow.providers.ezmeral.fs.sensors.ezfs.EzfsFolderSensor

Description: Waits for a non-empty directory.

API: The same API as [Apache HDFSFolder sensor](#).

WebEzfsSensor

Python path:

airflow.providers.ezmeral.fs.sensors.web_ezfs.WebEzfsSensor

Description: Waits for a file or folder to show up in the file system.

API: The same API as [Apache WebHDFS sensor](#).

Interface to Hive

Airflow provides an interface to Hive by using the Providers.

See Provider examples of Hive at <airflow_home>/build/env/lib/python3.9/site-packages/airflow/providers/ezmeral/hive/example_dags/.

Hooks

All hooks have the same API as [Apache Hive Hooks](#).

EzHiveCliHook

Python path:
 airflow.providers.ezmeral.hive.hooks.ezhive.EzHiveCliHook

Description: Provides access to Hive using Hive client.

EzHiveMetastoreHook

Python path:
 airflow.providers.ezmeral.hive.hooks.ezhive.EzHiveMetastoreHook

Description: Provides access to Hive Metastore using HMSClient.

EzHiveServer2Hook

Python path:
 airflow.providers.ezmeral.hive.hooks.ezhive.EzHiveServer2Hook

Description: Provides access to HiveServer using PyHive.

Operators**EzHiveOperator**

Python path:
 airflow.providers.ezmeral.hive.operators.ezhive.EzHiveOperator

Description: Executes HiveQL code or Hive script in a specific Hive database.

API: The same API as [Apache Hive Operator](#).

EzHiveStatsCollectionOperator

Python path:
 airflow.providers.ezmeral.hive.operators.ezhive_stats.EzHiveStatsCollectionOperator

Description: Gathers partition statistics using a dynamically generated Presto query and inserts the statistics into a MySQL table.

API: The same API as [Apache Hive Stats Operator](#).

Sensors**EzHivePartitionSensor**

Python path:
 airflow.providers.ezmeral.hive.sensors.ezhive_partition.EzHivePartitionSensor

Description: Waits for a partition to show up in Hive.

API: The same API as [Apache Hive Partition Sensor](#).

EzMetastorePartitionSensor

Python path:
 airflow.providers.ezmeral.hive.sensors.ezmetastore_partition.EzMetastorePartitionSensor

Description: An alternative to the HivePartitionSensor that talks directly to the MySQL database.

API: The same API as [Apache Hive Metastore Partition Sensor](#).

EzNamedHivePartitionSensor

Python path:
 airflow.providers.ezmeral.hive.sensors.eznamed_hive_partition.EzNamedHivePartitionSensor

Description: Waits for a set of partitions to show up in Hive.

API: The same API as [Apache Hive Named Partition Sensor](#).

Transfers

EzHiveToMySQLOperator

Python path:

airflow.providers.ezmeral.hive.transfers.ez_hive_to_mysql.EzHiveToMySQLOperator

Description: Moves data from Hive to MySQL. Use this operator to move small amount of data as data first loads into the memory and then into the MySQL.

API: The same API as [Apache HiveToMySQLOperator](#).

EzHiveToSambaOperator

Python path:

airflow.providers.ezmeral.hive.transfers.ez_hive_to_samba.EzHiveToSambaOperator

Description: Moves data from Hive to Samba. Executes HiveQL code in a specific Hive database and loads the results of the query as a CSV to a Samba location.

API: The same API as [Apache HiveToSambaOperator](#).

EzMsSqlToHiveOperator

Python path:

airflow.providers.ezmeral.hive.transfers.ez_mssql_to_hive.EzMsSqlToHiveOperator

Description: Moves data from Microsoft SQL Server to Hive.

API: The same API as [Apache MsSqlToHiveOperator](#).

EzMySQLToHiveOperator

Python path:

airflow.providers.ezmeral.hive.transfers.ez_mysql_to_hive.EzMySQLToHiveOperator

Description: Moves data from MySQL to Hive.

API: The same API as [Apache MySQLToHiveOperator](#).

EzS3ToHiveOperator

Python path:

airflow.providers.ezmeral.hive.transfers.ez_s3_to_hive.EzS3ToHiveOperator

Description: Moves data from Amazon S3 to Hive.

API: The same API as [Apache S3ToHiveOperator](#).

EzVerticaToHiveOperator

Python path:

airflow.providers.ezmeral.hive.transfers.ez_vertica_to_hive.EzVerticaToHiveOperator

Description: Moves data from Vertica to Hive.

API: The same API as [Apache VerticaToHiveOperator](#).

Configuring a HiveCliHook

Describes the properties that must be added to configure a HiveCliHook for Airflow on a secure cluster.

The HiveCliHook is a simple wrapper around the Hive CLI. To configure the HiveCliHook for Airflow:

1. Use the following connection properties:

Property	Value
use_beeline	true
auth	maprsasl
ssl	true

2. Add the following property to the `hive-site.xml` file:

```
<property>
  <name>hive.security.authorization.sqlstd.confwhitelist.append</name>
  <value>mapred.job.name|airflow.ctx.*</value>
</property>
```

Configuring Hook Connections for Hive High Availability

Describes how to configure the `EZHiveServer2Hook`, the `EzHiveCLIMHook`, and the `EzHiveMetastoreHook` to connect to Hive with High Availability (HA) enabled.

EEP 9.2.1 and later include hook connection support in Airflow to connect to `HiveServer2` with High Availability (HA) enabled. When any of the hooks are configured, if one of the HS2 servers is unreachable, Airflow connects to another server in the list of hosts that you specify.

Configuring the `EzHiveServer2Hook` for Hive HA

The `EZHiveServer2Hook` supports a `pyhive` connection to `HiveServer 2 HA`. To configure the `pyhive` connection with `HiveServer 2 HA`:

1. Add the `hive_ha` property to the `extra` section of the connection configuration. For example:

```
{
  "authMechanism": "MAPRSASL",
  "ssl": "true",
  "hive_ha": "true"
}
```

2. Add the list of your active HS2 instances in the `host` section using this format:

```
<hs2_hostname1>:<port1>,<hs2_hostname2>:<port2>,<hs2_hostname3>:<port3>...
```

For example:

```
myhost-48-n2.storage.mycorp.net:10000,myhost-23-n2.storage.mycorp.net:10000
```

In the following example, one of the HS2 servers is unusable, so Airflow reconnects to another server:

```
{ezhive.py:196} INFO - Trying to connect to
myhost-23-n2.storage.mycorp.net:10000
{TSocket.py:142} INFO - Could not connect to ('<ip_address>', 10000)
Traceback (most recent call last):
  File "/opt/mapr/airflow/airflow-2.7.3/build/env/lib/python3.9/
site-packages/thrift/transport/TSocket.py", line 137, in open
    handle.connect(sockaddr)
  File "/opt/mapr/airflow/airflow-2.7.3/build/python/lib/python3.9/ssl.py",
line 1343, in connect
    self._real_connect(addr, False)
  File "/opt/mapr/airflow/airflow-2.7.3/build/python/lib/python3.9/ssl.py",
line 1330, in _real_connect
    super().connect(addr)
ConnectionRefusedError: [Errno 111] Connection refused
{TSocket.py:145} ERROR - Could not connect to any of [('<ip_address>',
10000)]
[2023-12-15, 09:06:32 UTC] {ezhive.py:210} WARNING - Failed to connect to
myhost-23-n2.storage.mycorp.net:10000
{ezhive.py:196} INFO - Trying to connect to
```

```
myhost-48-n2.storage.mycorp.net:10000
{hive.py:475} INFO - USE 'default'
```

Configuring the EzHiveCliHook for Hive HA

The EzHiveCliHook supports a beeline connection to HiveServer 2 HA. To configure the beeline connection with HiveServer 2 HA:

1. Add the following properties to the extra section of the connection configuration:

```
{
  "use_beeline": true,
  "ssl": "true",
  "hive_ha": "true",
  "serviceDiscoveryMode": "zooKeeper",
  "zooKeeperNamespace": "hiveserver2"
}
```

2. Add the list of your active ZooKeeper instances in the host section using this format:

```
<ZK_FQDN1>:5181,<ZK_FQDN2>:5181,<ZK_FQDN3>:5181
```

Configuring the EzHiveMetastoreHook for Hive HA

The EzHiveMetastoreHook supports an hmsclient connection to HiveServer 2 HA. To configure the hmsclient connection with HiveServer 2 HA:

1. Configure Hive Metastore HA as described in [Enabling High Availability for Hive Metastore](#) on page 5082.
2. Add the following properties to the extra section of the connection configuration:

```
{  "authMechanism": "MAPRSASL"}
```

3. In the host section, specify the list of active Hive metastore hosts using the following format:

```
<hive_metastore1>,<hive_metastore2>,<hive_metastore3>
```

With this configuration, if one Hive metastore host is unavailable, a connection will be made to another host in the list. For example:

```
[2023-12-15, 12:57:54 UTC] {base.py:73} INFO - Using connection ID
'metastore_default' for task execution.
[2023-12-15, 12:57:54 UTC] {hive.py:576} INFO - Trying to connect to
myhost-23-n2.storage.mycorp.net:9083
[2023-12-15, 12:57:54 UTC] {hive.py:582} ERROR - Could not connect to
myhost-23-n2.storage.mycorp.net:9083
[2023-12-15, 12:57:54 UTC] {hive.py:576} INFO - Trying to connect to
myhost-48-n2.storage.mycorp.net:9083
[2023-12-15, 12:57:54 UTC] {hive.py:578} INFO - Connected to
myhost-48-n2.storage.mycorp.net:9083
```

[Ecosystem Pack Support and Lifecycle Status](#) on page 7664

This page shows the Ecosystem Packs that are supported for different core releases and the current lifecycle status for each EEP or DEP.

More information

[Enabling High Availability for Hive](#) on page 5079

This section describes how to enable High Availability for HiveServer2 and HiveMetastore.

Interface to Livy

Airflow provides an interface to Livy by using the Providers.

See Provider examples of Livy at <airflow_home>/build/env/lib/python3.9/site-packages/airflow/providers/ezmeral/livy/example_dags/.

Hooks

EzLivyHook

Python path:
airflow.providers.ezmeral.livy.hooks.ezlivy.EzLivyHook

Description: Apache Livy hook on HPE Data Fabric through the REST API.

API: The same API as [Apache LivyHook](#).

Operators

EzLivyOperator

Python path:
airflow.providers.ezmeral.livy.operators.ezlivy.EzLivyOperator

Description: Wraps the Livy batch REST API, enabling to submit a Spark application to the underlying cluster.

API: The same API as [Apache LivyOperator](#).

Sensors

EzLivySensor

Python path:
airflow.providers.ezmeral.livy.sensors.ezlivy.EzLivySensor

Description: Monitors Livy sessions for termination.

API: The same API as [Apache LivySensor](#).

Interface to Amazon S3

Airflow provides an interface to Amazon S3 by using the Providers.

See Provider examples of Amazon S3 at <airflow_home>/build/env/lib/python3.9/site-packages/airflow/providers/ezmeral/s3/example_dags/.

Hooks

EzS3Hook

Python path: airflow.providers.ezmeral.s3.hooks.s3

Description: Interacts with Amazon S3 using Boto3 library.

Operators

EzS3CreateBucketOperator

Python path:
airflow.providers.ezmeral.s3.operators.s3_bucket

Description: Creates an S3 bucket.

EzS3DeleteBucketOperator

Python path:
airflow.providers.ezmeral.s3.operators.s3_bucket

Description: Deletes an S3 bucket.

EzS3GetBucketTaggingOperator

Python path:
 airflow.providers.ezmeral.s3.operators.s3_bucket_tagging

Description: Gets tagging from an S3 bucket.

EzS3PutBucketTaggingOperator

Python path:
 airflow.providers.ezmeral.s3.operators.s3_bucket_tagging

Description: Puts tagging for an S3 bucket.

EzS3DeleteBucketTaggingOperator

Python path:
 airflow.providers.ezmeral.s3.operators.s3_bucket_tagging

Description: Deletes tagging from an S3 bucket.

EzS3CopyObjectOperator

Python path:
 airflow.providers.ezmeral.s3.operators.s3_copy_object

Description: Creates a copy of the stored S3 object.

EzS3DeleteObjectsOperator

Python path:
 airflow.providers.ezmeral.s3.operators.s3_delete_objects

Description: Deletes single or multiple objects from a bucket using a single HTTP request.

EzS3ListOperator

Python path:
 airflow.providers.ezmeral.s3.operators.s3_list

Description: List all objects from the bucket with the given string prefix in name.

Sensors**EzS3KeySensor**

Python path:
 airflow.providers.ezmeral.s3.sensors.s3_key

Description: Waits for a key to show up in a S3 bucket. S3 is a key-value store and key uniquely identifies the object in the bucket. S3 does not support folders and the path is just a key of resource.

EzS3KeyUnchangedSensor

Python path:
 airflow.providers.ezmeral.s3.sensors.s3_keys_unchanged

Description: Checks for changes in the number of objects at prefix in S3 bucket. This sensor returns True if the inactivity period has passed with no increase in the number of objects. This sensor might give an error when you use it in reschedule mode. Between rescheduled invocations, S3 bucket loses the state of the listed objects.

Transfers**EzGCSToS3Operator**

Python path:
 airflow.providers.ezmeral.s3.transfers.gcs_to_s3

Description: Synchronizes a Google Cloud Storage bucket with an Amazon S3 bucket.

EzLocalFilesystemToS3Operator

Python path:
 airflow.providers.ezmeral.s3.transfers.local_to_s3

Description: Uploads a file from a local filesystem to S3.

EzMongoToS3Operator

Python path:
`airflow.providers.ezmeral.s3.transfers.mongo_to_s3`

Description: Moves data from MongoDB using PyMongo to Amazon S3 using Boto.

EzSQLToS3Operator

Python path:
`airflow.providers.ezmeral.s3.transfers.sql_to_s3`

Description: Saves data from a specific SQL query into a file in S3.

EzS3ToFTPOperator

Python path:
`airflow.providers.ezmeral.s3.transfers.s3_to_ftp`

Description: Enables the transfer of files from S3 to a FTP server.

EzS3ToSFTPOperator

Python path:
`airflow.providers.ezmeral.s3.transfers.s3_to_sftp`

Description: Enables the transfer of files from S3 to a SFTP server.

EzSFTPToS3Operator

Python path:
`airflow.providers.ezmeral.s3.transfers.sftp_to_s3`

Description: Enables the transfer of files from a SFTP server to S3.

Interface to Spark

Airflow provides an interface to Spark by using the Providers.

See Provider examples of Spark at `<airflow_home>/build/env/lib/python3.9/site-packages/airflow/providers/ezmeral/spark/example_dags/`.

Hooks**EzSparkSubmitHook**

Python path:
`airflow.providers.ezmeral.spark.hooks.ezspark_submit`

Description: Launches Spark applications. This hook is a wrapper around the `spark-submit` binary to run a `spark-submit` job.

EzSparkSqlHook

Python path:
`airflow.providers.ezmeral.spark.hooks.ezspark_sql`

Description: Enables interaction with binary tables through `spark-sql`. This hook is a wrapper around the `spark-sql` binary.

EzSparkJDBCHook

Python path:
`airflow.providers.ezmeral.spark.hooks.ezspark_jdbc`

Description: Enables data transfers between JDBC databases and Apache Spark.

Operators**EzSparkSubmitOperator**

Python path:
`airflow.providers.ezmeral.spark.operators.ezspark_submit`

Description: This operator is a wrapper around the `spark-submit` binary to run a `spark-submit` job.

EzSparkSqlOperator

Python path:
`airflow.providers.ezmeral.spark.operators.ezspark_sql`

EzSparkJDBCOperator*Description:* Executes Spark SQL query.*Python path:*
airflow.providers.ezmeral.spark.operators.ezspark_jdbc*Description:* Extends the SparkSubmitOperator to enable data transfers between JDBC databases and Apache Spark.**Spark binary path requirement**

As of EEP release 9.1.0, you must define the fully-qualified path to the spark-submit binary when configuring the Airflow Spark connection. You can do this by adding the Spark binary path of the spark_default connection to the extra JSON field:

```
"spark-binary": "/opt/mapr/spark/spark-<spark_version>/bin/spark-submit"
```

If you need to overwrite this path, you can do so by adding the path to the DAG parameters:

```
spark_submit = SparkSubmitOperator(
    task_id='run_spark_job',
    application='/PATH/spark_application.jar',
    conn_id='spark_default',
    spark_binary='/opt/mapr/spark/spark-<spark_version>/bin/
    spark-submit',
```

Note that either method of specifying the full path name as described above (defining spark-binary in the extra JSON field or defining spark_binary as a parameter of spark_submit) must reference the correct fully-qualified path name of the spark-submit binary on the Airflow node. The path name could be different depending on which version of Spark is installed.

Interface to Drill

Airflow provides an interface to Drill by using the Providers.

See Provider examples of Drill at <airflow_home>/build/env/lib/python3.9/site-packages/airflow/providers/ezmeral/drill/examples/.

Hooks

All hooks have the same API as [Apache Drill Hooks](#).

EZDrillHook*Python path:*
airflow.providers.ezmeral.drill.hooks.ezdrill.EZDrillHook*Description:* This hook provides access to Drill using SQLAlchemy.

NOTE: EZDrillHook has two additional options for connection configuration:

- use_ssl: Sets whether the connection to Drill uses HTTPS. The default value is true.
- verify_ssl: The path to the server's TLS certificate. The default value is path to DF cluster truststore certificate.

AsyncHBase

Data Fabric provides a version of AsyncHBase that is modified to work with HPE Data Fabric Database binary tables. The Data Fabric version of AsyncHBase is based on the AsyncHBase library provides

asynchronous Java APIs to access HPE Data Fabric Database binary tables. The HBase Client version is based on the current EEP and Data Fabric version you are running. For more information, see the [Interoperability Matrices](#) on page 7650.

Configuring the Default Database for AsyncHBase

For AsyncHBase 1.7 and later, you can configure whether AsyncHBase accesses HBase tables or MapR-DB tables by default. If this value is not configured, AsyncHBase will determine the table type.

You can configure the default database in the `asynchbase.conf` file and the client application. A default database setting in the client application overrides the default database configuration in the `asynchbase.conf` file.

The process that AsyncHBase uses to access tables differs based on the default database configuration.

- When the default database is HBase, AsyncHBase accesses the table using the HBase port that was used to initialize the AsyncHBase client and the table name provided to the application.
- When the default database is MapR-DB, the table name provided to the application is translated to the MapR-DB table path, and then AsyncHBase accesses the table.
- When a default database is not configured, AsyncHBase first tries to access the table as a MapR-DB table. If that fails, it tries to access the table as an HBase table.

Set the Default Database using `asynchbase.conf`

To specify if AsyncHBase accesses HBase tables or MapR-DB tables:

1. Add the `mapr.hbase.default.db` parameter in the `asynchbase.conf` (`/opt/mapr/asynchbase/asynchbase-<version>/conf/asynchbase.conf`) file.
2. Set the value of `mapr.hbase.default.db` to one of the following values which will indicate the default database:
 - `hbase`
 - `maprdb`

Set the Default Database in the Client Application

Based on the database that you want as the default, add the following code in the client application:

- To access MapR-DB tables:

```
Config config = new Config();
String dbString = "maprdb";
config.overrideConfig(HBaseClient.CONFIG_PARAM_DEFAULT_DB, dbString);
HBaseClient client = new
HBaseClient(config);
```

- To access HBase tables:

```
Config config = new Config();
String dbString = "hbase";
config.overrideConfig(HBaseClient.CONFIG_PARAM_DEFAULT_DB, dbString);
HBaseClient client = new
HBaseClient(config);
```

Compiling and Running AsyncHBase Applications

When you compile or run AsyncHBase applications, you need to include the required AsyncHBase libraries.

To compile the application:

```
javac -cp `asynchbase
classpath`:$APP_CLASSPATH
<ProgramName>
```

To run the application, use one of the following commands:

- ```
java -cp `asynchbase
classpath`:$APP_CLASSPATH
<ProgramName>
```
- ```
asynchbase $APP_CLASSPATH
<ProgramName>
```

To include the AsyncHBase library in your maven project:

1. Add MapR's maven repository to the list of repositories in your project's pom.xml:

```
<repository>
<id>mapr-releases</id>
<url>https://repository.mapr.com/
maven/</url>
<snapshots><enabled>true</
enabled></snapshots>
<releases><enabled>true</enabled></
releases>
</repository>
```

2. Add the following dependency to the list of dependencies:

```
<dependency> <groupId>org.hbase</
groupId>
<artifactId>asynchbase</
artifactId>
<version><AsyncHBaseVersion>-mapr-<
MapREcoVersion></version> </
dependency>
```

NOTE: For example, if you are using AsyncHBase 1.7-1603, configure the following for the version dependency:

```
<version>1.7.0-mapr-1603</
version>
```

AsyncHBase Script

Data Fabric provides an AsyncHBase script that you can use to run applications and generate the AsyncHBase classpath.

The asynchbase script has the following syntax:

```
asynchbase <command> [<args>]
Commands:
classpath Dump AsyncHBase CLASSPATH
CLASSNAME Run the class named CLASSNAME
```

Parameters	Description
classpath	Dumps the AsyncHBase classpath. For example, you can use <code>asyncbase classpath</code> when you compile an application: <pre>javac -cp `asyncbase classpath`:\$APP_CLASSPATH <ProgramName></pre>
CLASSNAME	Runs the named class. For example: <pre>asyncbase <path to application> CLASSNAME</pre>

AsyncHBase Behavior with HPE Data Fabric Database Binary Tables

After you install AsyncHBase, you can use the AsyncHBase libraries to provide asynchronous access to HPE Data Fabric Database binary tables. However, it is important to note the behavior that is specific to using AsyncHBase with HPE Data Fabric Database.

The Scanner . setMaxNumKeyValues method, when run against HPE Data Fabric Database binary tables, does not behave as documented.

According to the AsyncHBase documentation, this [method](#) sets “the maximum number of KeyValues the server is allowed to return in a single RPC response.”

When you use this method with HPE Data Fabric Database binary tables, the value for the maximum number of key values is ignored and the full set of KeyValues is always returned.

List<RegionClientStats> regionStats() is not supported

As of AsyncHBase 1.7-1603, `List<RegionClientStats> regionStats()` is not supported and when it is used the API does not return statistics.

HPE Data Fabric Database ignores HBase configurations in the `asyncbase.conf` file

As of AsyncHBase 1.7-1603, the [conf object](#) can be used to override Hbase properties that were previously only configured in the `asyncbase.conf` file. The `asyncbase.conf` file is located in the `asyncbase` installation directory. HPE Data Fabric Database does not use these Hbase configurations and therefore they are ignored by HPE Data Fabric Database

Using OpenTSDB with AsyncHBase

OpenTSDB can use Data Fabric’s AsyncHBase to perform time-series data-plots on HPE Data Fabric Database binary tables.

The [OpenTSDB](#) software package provides a time-series database that collects user-specified data.

To use OpenTSDB with AsyncHBase, install and configure OpenTSDB from source files or from a package.

Installing OpenTSDB from Source Files

The following steps describe how to install OpenTSDB from source files.

Prerequisites

Be sure to install the OpenTSDB version that is required for your AsyncHBase version. AsyncHBase 1.6 requires OpenTSDB 2.0. AsyncHBase 1.7 requires OpenTSDB 2.2.

Procedure

1. Clone the opentsdb.git project and check out the OpenTSDB branch that you require.

NOTE:

For example:

```
$ git clone https://github.com/OpenTSDB/opentsdb.git
Cloning into 'opentsdb'...
remote: Counting objects: 5625, done.
remote: Compressing objects: 100% (76/76), done.
remote: Total 5625 (delta 51), reused 64 (delta 30)
Receiving objects: 100% (5625/5625), 27.15 MiB | 2.67 MiB/s, done.
Resolving deltas: 100% (3755/3755), done.
Checking connectivity... done.
$ cd opentsdb
$ git tag -l
mapr-1.1.0-release+5
v1.0.0
v2.0.0
...
$ git checkout v2.0.0
Switched to a new branch 'v2.0.0'
```

2. Install dependencies for graph generation:

```
$ yum install autoconf automake gnuplot
```

3. Replace the asynchbase.jar file with the Data Fabric version of that file:

```
$ yum install mapr-asynchbase
```

4. Run the build script:

```
./build.sh
```

5. If you want to use OpenTSDB with HPE Data Fabric Database tables, open the create_table.sh file (<OPENTSDDB_ROOT_INSTALL_DIR>/src/create_table.sh) and add "/" before the table names so that Data Fabric recognizes them as HPE Data Fabric Database tables: See [Example: create_table.sh](#) on page 4670.

6. Create tables:

```
env COMPRESSION=NONE;HBASE_HOME=/opt/mapr/hbase/hbase-<version>
<OPENTSDDB_ROOT_INSTALL_DIR>/src/create_table.sh
```

7. Run the following command to verify that the tables are created successfully:

```
hadoop fs -ls /
```

8. Create a simple metric to store, such as "sys.cpu.user":

```
./build/tsdb mkmetric sys.cpu.user --table=/tsdb --uidtable=/tsdb-uid
```

9. Run the OpenTSDB daemon (tsd).

```
./build/tsdb tsd --port=4242 --staticroot=build/staticroot
--cachedir=/tmp/opentsdb_tmp --zkquorum=10.10.101.50:5181 --table=/tsdb
--uidtable=/tsdb-uid
```

NOTE: Instead of providing these options on command line, you can configure the values in the `opentsdb.conf` file. This file must be in the root folder so the option settings are read when `tsd` is run. Also note that the `staticroot` argument points to the static UI files. You do not need to create `cachedir` because `opentsdb` creates it automatically. Specifying the destination `cachedir` argument is enough. You do need to explicitly specify `tsdb` tables (`tsdb`, `tsdb-uid`) and Zookeeper quorum nodes.

10. Log into the web UI: `http://<TSD_Installed_Node_IP>:<Port>`

For example: `http://10.10.10.230:4242/`

11. Run a simple test program that generates data and sends repeated puts for the metric over a socket connection: `<UI-IP>:<UI-Port>`. See [Data Generator Program](#) on page 4671.

12. Check the plot in the UI.

- a) Select **From date** and check **autoreload**.
- b) Fill in the metric (in this case, `sys.cpu.user`) and the Tag keys (`cpu`, `host`) values (`webserver 0`, `webserver 1`). You should see a graph with a random plot.

Example: create_table.sh

`create_table.sh` is used to set up HPE Data Fabric Database to accept puts from OpenTSDB. This example `create_table.sh` script was updated to work with HPE Data Fabric Database tables.

Note the changed sections for the `*_TABLE` variables.

```
#!/bin/sh
# Small script to setup the HBase tables used by OpenTSDB.

test -n "$HBASE_HOME" || {
    echo >&2 'The environment variable HBASE_HOME must be set'
    exit 1
}
test -d "$HBASE_HOME" || {
    echo >&2 "No such directory: HBASE_HOME=$HBASE_HOME"
    exit 1
}

TSDB_TABLE=${TSDB_TABLE-'/tsdb'}
UID_TABLE=${UID_TABLE-'/tsdb-uid'}
TREE_TABLE=${TREE_TABLE-'/tsdb-tree'}
META_TABLE=${META_TABLE-'/tsdb-meta'}
BLOOMFILTER=${BLOOMFILTER-'ROW'}
# LZ0 requires lzo2 64bit to be installed + the hadoop-gpl-compression jar.
COMPRESSION=${COMPRESSION-'LZO'}
# All compression codec names are upper case (NONE, LZ0, SNAPPY, etc).
COMPRESSION=`echo "$COMPRESSION" | tr a-z A-Z`

case $COMPRESSION in
    (NONE|LZO|GZIP|SNAPPY) ;; # Known good.
    (*)
        echo >&2 "warning: compression codec '$COMPRESSION' might not be
supported."
        ;;

```

```

esac

# HBase scripts also use a variable named `HBASE_HOME', and having this
# variable in the environment with a value somewhat different from what
# they expect can confuse them in some cases.  So rename the variable.
hbh=$HBASE_HOME
unset HBASE_HOME
exec "$hbh/bin/hbase" shell <<EOF
create '$UID_TABLE',
  {NAME => 'id', COMPRESSION => '$COMPRESSION', BLOOMFILTER =>
  '$BLOOMFILTER'},
  {NAME => 'name', COMPRESSION => '$COMPRESSION', BLOOMFILTER =>
  '$BLOOMFILTER'}

create '$TSDB_TABLE',
  {NAME => 't', VERSIONS => 1, COMPRESSION => '$COMPRESSION', BLOOMFILTER
=> '$BLOOMFILTER'}

create '$TREE_TABLE',
  {NAME => 't', VERSIONS => 1, COMPRESSION => '$COMPRESSION', BLOOMFILTER
=> '$BLOOMFILTER'}

create '$META_TABLE',
  {NAME => 'name', COMPRESSION => '$COMPRESSION', BLOOMFILTER =>
  '$BLOOMFILTER'}
EOF

```

Data Generator Program

This simple test program generates data and sends repeated puts for the metric over a socket connection.

```

import java.io.PrintWriter;
import java.net.Socket;
import java.util.Date;
import java.util.Random;

public class TestOpenTsdbAPI {
    public static Random random = new Random();
    public static long timeStamp = new Date().getTime()/1000; //in secs
    public static void testTSDBConnection() throws Exception {
        Socket sock = null;
        PrintWriter pw = null;
        String hostname = "10.10.10.230";
        int port = 4242;
        int count=1;
        while(true) {
            if(null==sock) {
                sock = new Socket(hostname, port);
                pw = new PrintWriter(sock.getOutputStream(), true);
            }
            pw.println(dataGen(0, 0, count));
            pw.flush();
            pw.println(dataGen(0, 1, count));
            pw.flush();
            pw.println(dataGen(1, 0, count));
            pw.flush();
            pw.println(dataGen(1, 1, count));
            pw.flush();

            if(++count==Integer.MAX_VALUE) break;
            Thread.sleep(60000);
        }
    }
    public static void main(String [] args) {

```

```

        try {
            testTSDBConnection();
        } catch (Exception ex) {
            ex.printStackTrace();
        }
    }

    public static String dataGen(int web, int cpu, int count) {
        int Low = 1;
        int High = 99;
        int val = random.nextInt(High-Low) + Low;
        long timeStamp1 = new Date().getTime()/1000;
        String dat = "put sys.cpu.user "+(timeStamp1)+" "+val+"
host=webserver"+ web +" cpu="+cpu;//(timeStamp+count)
        System.out.println(dat);
        return dat;
    }
}

```

For example, this program tries to put metrics for 2 hosts (webserver 0 and webserver 1). Each host has 2 CPUs (cpu 0 and cpu 1). Sample puts look like this:

```

put sys.cpu.user 1415300810 87 host=webserver0 cpu=0
put sys.cpu.user 1415300810 66 host=webserver0 cpu=1
put sys.cpu.user 1415300810 18 host=webserver1 cpu=0
put sys.cpu.user 1415300810 26 host=webserver1 cpu=1

put <metric> <timestamp> <value> <tag1>=<> <tag2>=<>

```

When you run the program, you should see entries that indicate that the tags for the metric were created, and they should auto-complete on the UI.

```

UniqueId: Creating an ID for kind='tagv' name='webserver0'

```

You can also verify this from command line instead of the UI:

```

<OpenTSDB-Root>/build/tsdb query 1y-ago sum sys.cpu.user

```

Installing OpenTSDB with a Package

The following steps describe how to install OpenTSDB from a package.

About this task

Be sure to install the OpenTSDB version that is required for your AsyncHBase version. AsyncHBase 1.6 requires OpenTSDB 2.0. AsyncHBase 1.7 requires OpenTSDB 2.2.

Procedure

1. Install the OpenTSDB RPM:

a) `mkdir /root/opentsdbrpm`

b) `cd /root/opentsdbrpm`

c) Download the version of OpenTSDB that you required.

For OpenTSDB 2.0: `wget https://github.com/OpenTSDB/opentsdb/releases/download/v2.0.0/opentsdb-2.0.0.noarch.rpm -O opentsdb-2.0.0.noarch.rpm`

For OpenTSDB 2.2: `wget https://github.com/OpenTSDB/opentsdb/releases/download/v2.2.0/opentsdb-2.2.0.noarch.rpm -O opentsdb-2.2.0.noarch.rpm`

d) `rpm -ivh opentsdb-<version>.noarch.rpm`

2. Configure OpenTSDB to work with Data Fabric:

a) Edit the following tsdb scripts to cover Data Fabric-specific dependencies: `/usr/share/opentsdb/bin/tsdb` and `/usr/bin/tsdb`

```
# Base of Data Fabric installation
BASEMAPR=${MAPR_HOME:-/opt/mapr}

# Add Data Fabric hadoop jars to classpath
if test -d "$BASEMAPR/hadoop/hadoop-0.20.2/lib"; then
# hadoop conf directory to beginning of classpath (for core-site.xml)
CLASSPATH="$BASEMAPR/hadoop/hadoop-0.20.2/conf:$CLASSPATH"

for jar in "$BASEMAPR"/hadoop/hadoop-0.20.2/lib/*.jar; do
    if [ "`echo $jar | grep slf4j`" != "" ]; then
        continue
    fi
    CLASSPATH="$CLASSPATH:$jar"
done
fi
```

b) Replace the asynchbase jar file (provide the current jar file name in the cp command):

```
cp
/opt/mapr/asynchbase/asynchbase-<version>/
asynchbase-<version>-mapr-*.jar
/usr/share/opentsdb/lib/
rm -f /usr/share/opentsdb/lib/asynchbase-<previous_version>.jar
```

c) Configure the `opentsdb.conf` files: These files must have the following settings:

```
/usr/share/opentsdb/etc/opentsdb/opentsdb.conf
/etc/opentsdb/opentsdb.conf
```

```
tsd.network.port = 4242
tsd.http.staticroot = /usr/share/opentsdb/static/
tsd.core.auto_create_metrics = false (for testing purposes only)
tsd.storage.hbase.data_table = /tsdb
tsd.storage.hbase.uid_table = /tsdb-uid
tsd.storage.hbase.zk_quorum = <zookeeperNode>:<zookeeperP>
```

d) Edit the `<OPENTSDB_ROOT_INSTALL_DIR>/src/create_table.sh` file and add `"/` before the table names so that Data Fabric recognizes them as HPE Data Fabric Database tables. Then, create tables in HPE Data Fabric Database: .

```
export COMPRESSION=NONE; export HBASE_HOME=/opt/mapr/hbase/
hbase-<version>; /usr/share/opentsdb/tools/create_table.sh
```

See [Example: create_table.sh](#) on page 4670

- e) Confirm that the tables are created:

```
hadoop fs -ls /
tr----- 3 root root          2 2014-12-12 01:47 /tsdb
tr----- 3 root root          2 2014-12-12 01:47 /tsdb-meta
tr----- 3 root root          2 2014-12-12 01:47 /tsdb-tree
tr----- 3 root root          2 2014-12-12 01:47 /tsdb-uid
```

3. Start the tsd daemon. You can give executable permissions to the tsdb script in /usr/share/opentsdb/bin, or you can directly use tsdb (because of the dependencies you added earlier).

```
chmod +x /usr/share/opentsdb/bin/tsdb
/usr/share/opentsdb/bin/tsdb tsd --port=4242
--staticroot="/usr/share/opentsdb/static/"
--cachedir="/tmp/opentsdb" --auto-metric
```

4. Create a metric: /usr/share/opentsdb/bin/tsdb mkmetric mymetric.stock

5. Test the metric:

- Run a [Test Program for OpenTSDB](#) on page 4675 that reads from the [tmp_input](#) on page 4674 file and sends put requests to opentsdb, which saves the data to a HPE Data Fabric Database table (tsdb/tsdb-uid).
- Run aggregation queries (such as SUM) from the command line: /usr/share/opentsdb/bin/tsdb query 1y-ago sum mymetric.stock or tsdb query 1y-ago sum mymetric.stock
- When you run the SUM command, the results should look like the following:

```
=====
mymetric.stock 1407165399000 680.500015 {}
mymetric.stock 1407165401000 904.625000 {}
mymetric.stock 1407165402000 904.612495 {}
mymetric.stock 1407165403000 904.599991 {}
mymetric.stock 1407165404000 904.599991 {}
mymetric.stock 1407165405000 904.599991 {}
mymetric.stock 1407165406000 904.599991 {}
mymetric.stock 1407165407000 904.599991 {}
mymetric.stock 1407165408000 904.599991 {}
mymetric.stock 1407165409000 904.599991 {}
mymetric.stock 1407165410000 904.599991 {}
mymetric.stock 1407165411000 904.599991 {}
mymetric.stock 1407165412000 904.599991 {}
mymetric.stock 1407165413000 904.599991 {}
mymetric.stock 1407165414000 904.599991 {}
mymetric.stock 1407165415000 904.599991 {}
mymetric.stock 1407165416000 904.599991 {}
mymetric.stock 1407165417000 904.599991 {}
mymetric.stock 1407165418000 904.599991 {}
mymetric.stock 1407165419000 904.599991 {}
mymetric.stock 1407165422000 904.678749 {}
mymetric.stock 1407165423000 484.255005 {}

```

Test Program for OpenTSDB

```

public static void testTSDBConnection() throws Exception {
    Socket sock = null;
    PrintWriter pw = null;
    String hostname = "10.10.10.220"; //replace with the node where tsd
runs
    int port = 4242; //replace with your port
    sock = new Socket(hostname, port);
    pw = new PrintWriter(sock.getOutputStream(), true);
    File dir = new File(".");
    File fin = new File(dir.getCanonicalPath() + File.separator +
"tmp_input");
    BufferedReader br = new BufferedReader(new FileReader(fin));
    String line = null;
    while ((line = br.readLine()) != null) {
        System.out.println(line);
        pw.println(line);
        pw.flush();
    }
    br.close();
}

```

GetRequest API

MapR includes an additional constructor for the GetRequest class which takes an extra qualifier.

This additional constructor allows you to use one GetRequest to retrieve the key and value for tables that consist of multiple column families with different qualifiers:

```

public GetRequest(final byte[] table,
                  final byte[] key,
                  final byte[][] families,
                  final byte[][][] qualifiers) {
    super(table, key);
}

```

```

    this.families(families);
    this.qualifiers(qualifiers);
}

```

Cascading

Cascading™ is a Java application framework produced by Concurrent, Inc. that enables developers to quickly and easily build rich enterprise-grade Data Processing and Machine Learning applications that can be deployed and managed across private or cloud-based Hadoop clusters.

NOTE: Cascading is *not* part of the HPE Data Fabric distribution and not supported by HPE. However, like many other open source technologies, it can be used with HPE Data Fabric. The following information provides relevant details about using Cascading with HPE Data Fabric.

The `mt` command is the wrapper around Cascading. Multitool, a command line tool for processing large text files and datasets (like `sed` and `grep` on unix). The `mt` command is located in the `/opt/mapr/contrib/multitool/bin` directory.

Apache Drill

Drill is a low-latency distributed query engine for large-scale datasets, including structured and semi-structured/nested data. Inspired by Google's Dremel, Drill is designed to scale to several thousands of nodes and query petabytes of data at interactive speeds that BI/Analytics environments require.

Drill includes a distributed environment, purpose built for large-scale data processing. At the core of Drill is the "Drillbit" service which is responsible for accepting requests from the client, processing the queries, and returning results to the client.

Installing Drill

You can install Drill on one node or multiple nodes in a cluster. When Drill runs on each data node in a cluster, Drill can maximize data locality without moving data over the network or between nodes. Drill uses ZooKeeper to maintain cluster membership and health check information.

See [Installing Drill](#) on page 288 for instructions and additional information.

Configuring Data Source Connections

Drill connects to data sources through storage plugins. Drill can connect to several types of data sources including databases, local or distributed filesystems, and Hive metastores.

See [Connecting Drill to Data Sources](#) on page 4749 and [Connect a Data Source](#) for instructions and additional information.

Accessing Drill

After you install Drill and configure connections to your data sources, you can access Drill from any of the following user interfaces:

- [Drill shell \(SQLLine\)](#)
- [Drill Web Console](#)
- [ODBC](#)
- [JDBC](#)
- C++ API
- [REST API](#)

Additional Resources

Drill documentation is accessible from following the locations:

- [Drill Release Notes](#) on page 7847
- [Apache Drill](#)

Drill Tutorial

Drill is included as part of the Hadoop distribution. Refer to the [Drill web site](#) and [Drill documentation](#) for more details.

Hadoop is not a prerequisite for Drill and users can start learning Drill by running SQL queries directly on the local filesystem.

Getting to Know the Drill Setup

This section describes the configuration of the Drill system that you have installed and introduces the overall use case for the tutorial.

Storage Plugins Overview

The Hadoop cluster is set up with file system, HPE Data Fabric Database, and Hive, which all serve as data sources for Drill in this tutorial. Before you can run queries against these data sources, you need to connect to the data source through an interface called a storage plugin. A storage plugin defines interfaces to read/write and get metadata from the data source. Each storage plugin also exposes optimization rules for Drill to leverage for efficient query execution.

Jump directly to the queries in [Lesson 1: Learn About the Data Set](#), or first, get some important background information about pre-configured storage plugins by following these steps:

1. [Start the Drill Web Console](#).
2. Go to the Storage tab.

3. Open the configured storage plugins one at a time by clicking Update. You will see the following plugins configured.

dfs

This is a storage plugin configuration for the file system. The connection attribute indicates the type of distributed filesystem: in this case, file system. Drill can work with any distributed system, including HDFS, S3, and so on.

The configuration also includes a set of workspaces; each one represents a location in file system:

- root: access to the root filesystem location
- clicks: access to nested JSON log data
- logs: access to flat (non-nested) JSON log data in the logs directory and its subdirectories
- views: a workspace for creating views

A workspace in Drill is a location where users can easily access a specific set of data and collaborate with each other by sharing artifacts. Users can create as many workspaces as they need within Drill.

Each workspace can also be configured as “writable” or not, which indicates whether users can write data to this location and defines the storage format in which the data will be written (parquet, csv, json). These attributes become relevant when you explore Drill SQL commands, especially CREATE TABLE AS (CTAS) and CREATE VIEW.

Drill can query files and directories directly and can detect the file formats based on the file extension or the first few bits of data within the file. However, additional information around formats is required for Drill, such as delimiters for text files, which are specified in the “formats” section as follows.

```
{
  "type": "file",
  "enabled": true,
  "connection": "maprfs://",
  "workspaces": {
    "root": {
      "location": "/mapr/demo.mapr.com/data",
      "writable": false,
      "storageformat": null
    },
    "clicks": {
      "location": "/mapr/demo.mapr.com/data/nested",
      "writable": true,
      "storageformat": "parquet"
    },
    "logs": {
      "location": "/mapr/demo.mapr.com/data/flat",
      "writable": true,
      "storageformat": "parquet"
    },
    "views": {
      "location": "/mapr/demo.mapr.com/data/views",
      "writable": true,
      "storageformat": "parquet"
    }
  },
  "formats": {
    "psv": {
      "type": "text",

    }
  }
}

```

hive

A storage plugin configuration for a Hive data warehouse. Drill connects to the Hive metastore by using the configured metastore thrift URI. Metadata for Hive tables is automatically available for users to query.

```

{
  "type": "hive",
  "enabled": true,
  "configProps": {
    "hive.metastore.uris": "thrift://localhost:9083",
    "hive.metastore.sasl.enabled": "false"
  }
}

```

Client Application Interfaces

Drill also provides additional application interfaces for the client tools to connect and access from Drill. The interfaces include the following.

ODBC/JDBC drivers

Drill provides ODBC/JDBC drivers to connect from BI tools such as Tableau, MicroStrategy, SQUIRREL, and Jaspersoft; refer to [Drill Interfaces Introduction](#) to learn more.

SQLLine

SQLLine is a JDBC application that comes packaged with Drill. In order to start working with it, you can use the command line on the demo cluster to log in as root, then enter sqlline. Use mapr as the login password. For example:

```

$ ssh root@localhost -p 2222
Password:
Last login: Mon Sep 15 13:46:08 2014 from 10.250.0.28
Welcome to your Mapr Demo virtual machine.
[root@maprdemo ~]# sqlline
sqlline version 1.1.6
0: jdbc:drill:>

```

Drill Web UI

The Drill Web UI is a simple user interface for configuring and manage Drill. This UI can be launched from any of the nodes in the Drill cluster. The configuration for Drill includes setting up storage plugins that represent the data sources on which Drill performs queries. .

Users and developers can get the necessary information for tuning and performing diagnostics on queries, such as the list of queries executed in a session and detailed query plan profiles for each.

Detailed configuration and management of Drill is out of scope for this tutorial.

The following Web Console for Drill also provides a query UI where users can submit queries to Drill and observe results.

What's Next

Start running queries by going to [Lesson 1: Learn About the Data Set](#).

Lesson 1: Learn About the Data Set

Goal

This lesson is simply about discovering what data is available, in what format, using simple SQL SELECT statements. Drill is capable of analyzing data without prior knowledge or definition of its schema. This means that you can start querying data immediately (and even as it changes), regardless of its format.

The data set for the tutorial consists of:

- Transactional data: stored as a Hive table
- Product catalog and primary customer data: stored as HPE Data Fabric Database binary tables
- Clickstream and logs data: stored in the file system as JSON files

Queries in This Lesson

This lesson consists of select * queries on each data source.

Before You Begin

Start sqlline

If sqlline is not already started, use a Terminal or Command window to log into the demo VM as root, then enter sqlline:

```
$ ssh root@10.250.0.6
Password:
Last login: Mon Sep 15 13:46:08 2014 from 10.250.0.28
Welcome to your Mapr Demo virtual machine.
[root@maprdemo ~]# sqlline
sqlline version 1.1.6
0: jdbc:drill:>
```

You can run queries from this prompt to complete the tutorial. To exit from sqlline, type:

```
0: jdbc:drill:> !quit
```

Note that though this tutorial demonstrates the queries using SQLLine, you can also execute queries using the Drill Web UI.

Enable the DECIMAL Data Type

This tutorial uses the DECIMAL data type in some examples. The DECIMAL data type is disabled by default in this release, so enable the DECIMAL data type before proceeding:

```
alter session set `planner.enable_decimal_data_type`=true;
```

```
+-----+-----+
| ok      | summary                                     |
+-----+-----+
| true    | planner.enable_decimal_data_type updated. |
+-----+-----+
1 row selected
```

List the available workspaces and databases:

```
0: jdbc:drill:> show databases;
+-----+
| SCHEMA_NAME |
+-----+
| hive.default |
| dfs.default  |
| dfs.logs     |
| dfs.root     |
| dfs.views    |
| dfs.clicks   |
| dfs.data     |
| dfs.tmp      |
| sys          |
| maprdb       |
| cp.default   |
| INFORMATION_SCHEMA |
+-----+
12 rows selected
```

Note that this command exposes all the metadata available from the storage plugins configured with Drill as a set of schemas. This includes the Hive and HPE Data Fabric Database databases as well as the workspaces configured in the file system. As you run queries in the tutorial, you will switch among these schemas by submitting the USE command. This behavior resembles the ability to use different database schemas (namespaces) in a relational database system.

Query Hive Tables

The orders table is a six-column Hive table defined in the Hive metastore. This is a Hive external table pointing to the data stored in flat files on the file system. The orders table contains 122,000 rows.

Set the schema to hive:

```
0: jdbc:drill:> use hive;
+-----+
| ok | summary |
+-----+
| true | Default schema changed to 'hive' |
+-----+
```

You will run the USE command throughout this tutorial. The USE command sets the schema for the current session.

Describe the table:

You can use the DESCRIBE command to show the columns and data types for a Hive table:

```
0: jdbc:drill:> describe orders;
+-----+-----+-----+
| COLUMN_NAME | DATA_TYPE | IS_NULLABLE |
+-----+-----+-----+
| order_id    | BIGINT     | YES         |
| month       | VARCHAR    | YES         |
| cust_id     | BIGINT     | YES         |
| state       | VARCHAR    | YES         |
| prod_id     | BIGINT     | YES         |
| order_total | INTEGER    | YES         |
+-----+-----+-----+
```

The DESCRIBE command returns complete schema information for Hive tables based on the metadata available in the Hive metastore.

Select 5 rows from the orders table:

```
0: jdbc:drill:> select * from orders limit 5;
+-----+-----+-----+-----+-----+-----+
| order_id | month | cust_id | state | prod_id | order_total |
+-----+-----+-----+-----+-----+-----+
| 67212    | June  | 10001   | ca    | 909     | 13          |
| 70302    | June  | 10004   | ga    | 420     | 11          |
| 69090    | June  | 10011   | fl    | 44      | 76          |
| 68834    | June  | 10012   | ar    | 0       | 81          |
| 71220    | June  | 10018   | az    | 411     | 24          |
+-----+-----+-----+-----+-----+-----+
```

Because orders is a Hive table, you can query the data in the same way that you would query the columns in a relational database table. Note the use of the standard LIMIT clause, which limits the result set to the specified number of rows. You can use LIMIT with or without an ORDER BY clause.

Drill provides seamless integration with Hive by allowing queries on Hive tables defined in the metastore with no extra configuration. Note that Hive is not a prerequisite for Drill, but simply serves as a storage plugin or data source for Drill. Drill also lets users query all Hive file formats (including custom serdes). Additionally, any UDFs defined in Hive can be leveraged as part of Drill queries.

Because Drill has its own low-latency SQL query execution engine, you can query Hive tables with high performance and support for interactive and ad-hoc data exploration.

Query HPE Data Fabric Database Binary Tables

The customers and products tables are HPE Data Fabric Database binary tables. HPE Data Fabric Database is an enterprise in-Hadoop NoSQL database. It exposes the HBase API to support application development. Every HPE Data Fabric Database binary table has a `row_key`, in addition to one or more column families. Each column family contains one or more specific columns. The `row_key` value is a primary key that uniquely identifies each row.

Drill allows direct queries on HPE Data Fabric Database binary tables. Unlike other SQL on Hadoop options, Drill requires no overlay schema definitions in Hive to work with this data. Think about a HPE Data Fabric Database table with thousands of columns, such as a time-series database, and the pain of having to management duplicate schemas for it in Hive!

Products Table

The products table has two column families.

Column Family	Columns
details	name category
pricing	price

The products table contains 965 rows.

Customers Table

The Customers table has three column families.

Column Family	Columns
address	state
loyalty	agg_rev membership
personal	age gender

The customers table contains 993 rows.

Set the workspace to maprdb:

```
0: jdbc:drill:> use maprdb;
+-----+
| ok | summary |
+-----+
| true | Default schema changed to 'maprdb' |
+-----+
```

Describe the tables:

```
0: jdbc:drill:> describe customers;
+-----+-----+-----+
| COLUMN_NAME | DATA_TYPE | IS_NULLABLE |
+-----+-----+-----+
| row_key     | ANY        | NO          |
| address     | (VARCHAR(1), ANY) MAP | NO          |
| loyalty     | (VARCHAR(1), ANY) MAP | NO          |
| personal    | (VARCHAR(1), ANY) MAP | NO          |
+-----+-----+-----+

0: jdbc:drill:> describe products;
+-----+-----+-----+
| COLUMN_NAME | DATA_TYPE | IS_NULLABLE |
+-----+-----+-----+
| row_key     | ANY        | NO          |
| details     | (VARCHAR(1), ANY) MAP | NO          |
| pricing     | (VARCHAR(1), ANY) MAP | NO          |
+-----+-----+-----+
```

Unlike the Hive example, the DESCRIBE command does not return the full schema up to the column level. Column-oriented NoSQL databases such as HPE Data Fabric Database can be schema-less by design; every row has its own set of column name-value pairs in a given column family, and the column value can be of any data type, as determined by the application inserting the data.

A “MAP” complex type in Drill represents this variable column name-value structure, and “ANY” represents the fact that the column value can be of any data type. Observe the `row_key`, which is also simply bytes and has the type ANY.

Select 5 rows from the products table:

```
0: jdbc:drill:> select * from products limit 5;
+-----+-----+-----+
| row_key | details | pricing |
+-----+-----+-----+
| [B@a1a3e25 | {"category":"bGFwdG9w", "name":"I1Nvbnkgbm90ZWJvb2si"} | {"price":"0TU5"} |
| [B@103a43af | {"category":"RW52ZWxvcGVz", "name":"IzEwLTQgMS84IHggOSAxLzIgUHJlbWl1bSBEawFnb25hbCBTZWFtIEVudmVsb3Blcw=="} | {"price":"MT |
| [B@61319e7b | {"category":"U3RvcnFnZSAmIE9yZ2FuaXphdGlvbg==", "name":"MjQgQ2FwYWNPdHkgTWf4aSBeyXRhIEJpbmRlciBSYWNrc1BLYXJs"} | {"price" |
| [B@9bcf17 | {"category":"TGFzZmxz", "name":"QXZlcnkgNDk4"} | {"price":"Mw=="} |
| [B@7538ef50 | {"category":"TGFzZmxz", "name":"QXZlcnkgNDk="} | {"price":"Mw=="} |
```

Given that Drill requires no up front schema definitions indicating data types, the query returns the raw byte arrays for column values, just as they are stored in HPE Data Fabric Database. Observe that the column families (details and pricing) have the map data type and appear as JSON strings.

In Lesson 2, you will use CAST functions to return typed data for each column.

Select 5 rows from the customers table:

```
0: jdbc:drill:> select * from customers limit 5;
+-----+-----+-----+-----+
| row_key | address | loyalty | personal |
+-----+-----+-----+-----+
```

```
| [B@284bae62 | {"state":"Imt5Ig=="} |
{"agg_rev":"IjEwMDEtMzAwMCI=", "membership":"ImJhc2ljIg=="} |
{"age":"IjI2LTM1Ig==", "gender":"Ik1B |
| [B@7ffa4523 | {"state":"ImNhIg=="}
| {"agg_rev":"IjAtMTAwIg==", "membership":"ImdvbGQi"} |
{"age":"IjI2LTM1Ig==", "gender":"IkZFTUFMRSI= |
| [B@7d13e79 | {"state":"Im9rIg=="} |
{"agg_rev":"IjUwMS0xMDAwIg==", "membership":"InNpbHZlciI="} |
{"age":"IjI2LTM1Ig==", "gender":"IkZFT |
| [B@3a5c7df1 | {"state":"ImtzIg=="} |
{"agg_rev":"IjMwMDEtMTAwMDAwIg==", "membership":"ImdvbGQi"} |
{"age":"IjUxLTUwMCI=", "gender":"IkZF |
| [B@e507726 | {"state":"Im5qIg=="}
| {"agg_rev":"IjAtMTAwIg==", "membership":"ImJhc2ljIg=="} |
{"age":"IjIxLTI1Ig==", "gender":"Ik1BTEUi" |
+-----+-----+-----+-----+
```

Again the table returns byte data that needs to be cast to readable data types.

Query the File System

Along with querying a data source with full schemas (such as Hive) and partial schemas (such as HPE Data Fabric Database), Drill offers the unique capability to perform SQL queries directly on file system. The file system could be a local file system, or a distributed file system such as file system, HDFS, or S3.

In the context of Drill, a file or a directory is considered as synonymous to a relational database “table.” Therefore, you can perform SQL operations directly on files and directories without the need for up-front schema definitions or schema management for any model changes. The schema is discovered on the fly based on the query. Drill supports queries on a variety of file formats including text, CSV, Parquet, and JSON in the 0.5 release.

In this example, the clickstream data coming from the mobile/web applications is in JSON format. The JSON files have the following structure:

```
{"trans_id":31920,"date":"2014-04-26","time":"12:17:12","user_info":
{"cust_id":22526,"device":"IOS5","state":"il"},"trans_info":{"prod_id":
[174,2],"purch_flag":"false"}}
{"trans_id":31026,"date":"2014-04-20","time":"13:50:29","user_info":
{"cust_id":16368,"device":"AOS4.2","state":"nc"},"trans_info":{"prod_id":
[],"purch_flag":"false"}}
{"trans_id":33848,"date":"2014-04-10","time":"04:44:42","user_info":
{"cust_id":21449,"device":"IOS6","state":"oh"},"trans_info":{"prod_id":
[582],"purch_flag":"false"}}
```

The clicks.json and clicks.campaign.json files contain metadata as part of the data itself (referred to as “self-describing” data). Also note that the data elements are complex, or nested. The initial queries below do not show how to unpack the nested data, but they show that easy access to the data requires no setup beyond the definition of a workspace.

Query nested clickstream data

Set the workspace to dfs.clicks:

```
0: jdbc:drill:> use dfs.clicks;
+-----+-----+
| ok | summary |
+-----+-----+
| true | Default schema changed to 'dfs.clicks' |
+-----+-----+
```

In this case, setting the workspace is a mechanism for making queries easier to write. When you specify a file system workspace, you can shorten references to files in the FROM clause of your queries. Instead of having to provide the complete path to a file, you can provide the path relative to a directory location specified in the workspace. For example:

```
"location": "/mapr/demo.mapr.com/data/nested"
```

Any file or directory that you want to query in this path can be referenced relative to this path. The clicks directory referred to in the following query is directly below the nested directory.

Select 2 rows from the clicks.json file:

```
0: jdbc:drill:> select * from `clicks/clicks.json` limit 2;
+-----+-----+-----+-----+-----+
| trans_id | date   | time   | user_info | trans_info |
+-----+-----+-----+-----+-----+
| 31920    | 2014-04-26 | 12:17:12 | {"cust_id":22526,"device":"IOS5","state":"il"} | {"prod_id":
[174,2],"purch_flag":"false"} |
| 31026    | 2014-04-20 | 13:50:29 | {"cust_id":16368,"device":"AOS4.2","state":"nc"} | {"prod_id":
[],"purch_flag":"false"} |
+-----+-----+-----+-----+-----+
2 rows selected
```

Note that the FROM clause reference points to a specific file. Drill expands the traditional concept of a “table reference” in a standard SQL FROM clause to refer to a file in a local or distributed file system.

The only special requirement is the use of back ticks to enclose the file path. This is necessary whenever the file path contains Drill reserved words or characters.

Select 2 rows from the campaign.json file:

```
0: jdbc:drill:> select * from `clicks/clicks.campaign.json` limit 2;
+-----+-----+-----+-----+-----+-----+
| trans_id | date   | time   | user_info | ad_info |
| trans_info |
+-----+-----+-----+-----+-----+-----+
| 35232    | 2014-05-10 | 00:13:03 | {"cust_id":18520,"device":"AOS4.3","state":"tx"} | {"camp_id":"null"} |
| {"prod_id":[7,7],"purch_flag":"true"} |
| 31995    | 2014-05-22 | 16:06:38 | {"cust_id":17182,"device":"IOS6","state":"fl"} | {"camp_id":"null"} |
| {"prod_id":[],"purch_flag":"false"} |
+-----+-----+-----+-----+-----+-----+
2 rows selected
```

Notice that with a select * query, any complex data types such as maps and arrays return as JSON strings. You will see how to unpack this data using various SQL functions and operators in the next lesson.

Query Logs Data

Unlike the previous example where we performed queries against clicks data in one file, logs data is stored as partitioned directories on the file system. The logs directory has three subdirectories:

- 2012

- 2013
- 2014

Each of these year directories fans out to a set of numbered month directories, and each month directory contains a JSON file with log records for that month. The total number of records in all log files is 48000.

The files in the logs directory and its subdirectories are JSON files. There are many of these files, but you can use Drill to query them all as a single data source, or to query a subset of the files.

Set the workspace to dfs.logs:

```
0: jdbc:drill:> use dfs.logs;
+-----+
| ok | summary |
+-----+
| true | Default schema changed to 'dfs.logs' |
+-----+
```

Select 2 rows from the logs directory:

```
0: jdbc:drill:> select * from logs limit 2;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| dir0 | dir1 | trans_id | date | time | cust_id | device | state | camp_id |
| keywords | prod_id | purch_fl |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 2014 | 8 | 24181 | 08/02/2014 | 09:23:52 | 0 | IOS5 | il | 2 | wait | 128 |
| false |
| 2014 | 8 | 24195 | 08/02/2014 | 07:58:19 | 243 | IOS5 | mo | 6 | hmm |
107 | false |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
```

Note that this is flat JSON data. The dfs.clicks workspace location property points to a directory that contains the logs directory, making the FROM clause reference for this query very simple. You do not have to refer to the complete directory path on the file system.

The column names dir0 and dir1 are special Drill variables that identify subdirectories below the logs directory. In Lesson 3, you will do more complex queries that leverage these dynamic variables.

Find the total number of rows in the logs directory (all files):

```
0: jdbc:drill:> select count(*) from logs;
+-----+
| EXPR$0 |
+-----+
| 48000 |
+-----+
```

This query traverses all of the files in the logs directory and its subdirectories to return the total number of rows in those files.

What's Next

Go to Lesson 2: [Run Queries with ANSI SQL](#).

Lesson 2: Run Queries with ANSI SQL

Goal

This lesson shows how to do some standard SQL analysis in Drill: for example, summarizing data by using simple aggregate functions and connecting data sources by using joins. Note that Drill provides ANSI SQL support, not a “SQL-like” interface.

Queries in This Lesson

Now that you know what the data sources look like in their raw form, using select * queries, try running some simple but more useful queries on each data source. These queries demonstrate how Drill supports ANSI SQL constructs and also how you can combine data from different data sources in a single SELECT statement.

- Show an aggregate query on a single file or table. Use GROUP BY, WHERE, HAVING, and ORDER BY clauses.
- Perform joins between Hive, HPE Data Fabric Database, and file system data sources.
- Use table and column aliases.
- Create a Drill view.

Aggregation

Set the schema to hive:

```
0: jdbc:drill:> use hive;
+-----+-----+
|      ok      | summary |
+-----+-----+
| true         | Default schema changed to 'hive' |
+-----+-----+
1 row selected
```

Return sales totals by month:

```
0: jdbc:drill:> select `month`, sum(order_total)
from orders group by `month` order by 2 desc;
+-----+-----+
| month | EXPR$1 |
+-----+-----+
| June  | 950481 |
| May   | 947796 |
| March | 836809 |
| April | 807291 |
| July  | 757395 |
| October | 676236 |
| August | 572269 |
| February | 532901 |
| September | 373100 |
| January | 346536 |
+-----+-----+
```

Drill supports SQL aggregate functions such as SUM, MAX, AVG, and MIN. Standard SQL clauses work in the same way in Drill queries as in relational database queries.

Note that back ticks are required for the “month” column only because “month” is a reserved word in SQL.

Return the top 20 sales totals by month and state:

```
0: jdbc:drill:> select `month`, state, sum(order_total) as sales from
orders group by `month`, state
order by 3 desc limit 20;
```

month	state	sales
May	ca	119586
June	ca	116322
April	ca	101363
March	ca	99540
July	ca	90285
October	ca	80090
June	tx	78363
May	tx	77247
March	tx	73815
August	ca	71255
April	tx	68385
July	tx	63858
February	ca	63527
June	fl	62199
June	ny	62052
May	fl	61651
May	ny	59369
October	tx	55076
March	fl	54867
March	ny	52101

20 rows selected

Note the alias for the result of the SUM function. Drill supports column aliases and table aliases.

HAVING Clause

This query uses the HAVING clause to constrain an aggregate result.

Set the workspace to dfs.clicks

```
0: jdbc:drill:> use dfs.clicks;
```

ok	summary
true	Default schema changed to 'dfs.clicks'

1 row selected

Return total number of clicks for devices that indicate high click-throughs:

```
0: jdbc:drill:> select t.user_info.device, count(*) from `clicks/
clicks.json` t
group by t.user_info.device
having count(*) > 1000;
```

EXPR\$0	EXPR\$1
I0S5	11814
A0S4.2	5986
I0S6	4464
I0S7	3135
A0S4.4	1562

A0S4.3	3039
--------	------

The aggregate is a count of the records for each different mobile device in the clickstream data. Only the activity for the devices that registered more than 1000 transactions qualify for the result set.

UNION Operator

Use the same workspace as before (dfs.clicks).

Combine clicks activity from before and after the marketing campaign

```
0: jdbc:drill:> select t.trans_id transaction, t.user_info.cust_id customer
from `clicks/clicks.campaign.json` t
union all
select u.trans_id, u.user_info.cust_id from `clicks/clicks.json` u limit 5;
```

transaction	customer
35232	18520
31995	17182
35760	18228
37090	17015
37838	18737

This UNION ALL query returns rows that exist in two files (and includes any duplicate rows from those files): clicks.campaign.json and clicks.json.

Subqueries

Set the workspace to hive:

```
0: jdbc:drill:> use hive;
```

ok	summary
----	---------

```
| true          | Default schema changed to 'hive' |
```

Compare order totals across states:

```
0: jdbc:drill:> select ny_sales.cust_id, ny_sales.total_orders,
ca_sales.total_orders
from
(select o.cust_id, sum(o.order_total) as total_orders
from hive.orders o where state = 'ny' group by o.cust_id) ny_sales
left outer join
(select o.cust_id, sum(o.order_total) as total_orders
from
hive.orders o where state = 'ca' group by o.cust_id) ca_sales
on ny_sales.cust_id = ca_sales.cust_id
order by ny_sales.cust_id
limit 20;
```

cust_id	ny_sales	ca_sales
1001	72	47
1002	108	198

1003	83	null
1004	86	210
1005	168	153
1006	29	326
1008	105	168
1009	443	127
1010	75	18
1012	110	null
1013	19	null
1014	106	162
1015	220	153
1016	85	159
1017	82	56
1019	37	196
1020	193	165
1022	124	null
1023	166	149
1024	233	null

This example demonstrates Drill support for correlated subqueries. This query uses a subquery in the select list and correlates the result of the subquery with the outer query, using the `cust_id` column reference. The subquery returns the sum of order totals for California, and the outer query returns the equivalent sum, for the same `cust_id`, for New York.

The result set is sorted by the `cust_id` and presents the sales totals side by side for easy comparison. Null values indicate customer IDs that did not register any sales in that state.

CAST Function

Use the `maprdb` workspace:

```
0: jdbc:drill:> use maprdb;
+-----+-----+
|      ok      | summary |
+-----+-----+
| true         | Default schema changed to 'maprdb' |
+-----+-----+
1 row selected
```

Return customer data with appropriate data types

```
0: jdbc:drill:> select cast(row_key as int) as cust_id,
cast(t.personal.name as varchar(20)) as name,
cast(t.personal.gender as varchar(10)) as gender, cast(t.personal.age as
varchar(10)) as age,
cast(t.address.state as varchar(4)) as state, cast(t.loyalty.agg_rev as
dec(7,2)) as agg_rev,
cast(t.loyalty.membership as varchar(20)) as membership
from customers t limit 5;
```

cust_id	name	gender	age	state	agg_rev	membership
10001	"Corrine Mecham"	"FEMALE"	"15-20"	"va"	197.00	"silver"
10005	"Brittany Park"	"MALE"	"26-35"	"in"	230.00	"silver"
10006	"Rose Lokey"	"MALE"	"26-35"	"ca"		

```

250.00 | "silver" |
| 10007 | "James Fowler" | "FEMALE" | "51-100" | "me" |
263.00 | "silver" |
| 10010 | "Guillermo Koehler" | "OTHER" | "51-100" | "mn" |
202.00 | "silver" |
+-----+-----+-----+-----+-----+-----+

```

5 rows selected

Note the following features of this query:

- The CAST function is required for every column in the table. This function returns the HPE Data Fabric Database/HBase binary data as readable integers and strings. Depending on what encoding is used while populating the HPE Data Fabric Database binary tables/HBase tables, you might have to use CONVERT_TO/CONVERT_FROM functions to decode them.
- The row_key column functions as the primary key of the table (a customer ID in this case).
- The table alias t is required; otherwise the column family names would be parsed as table names and the query would return an error.

Remove the quotes from the strings:

You can use the regexp_replace function to remove the quotes around the strings in the query results. For example, to return a state name va instead of "va":

```

0: jdbc:drill:> select cast(row_key as int),
regexp_replace(cast(t.address.state as varchar(10)),'"', '')
from customers t limit 1;
+-----+-----+
|  EXPR$0 |  EXPR$1 |
+-----+-----+
| 10001   | va      |
+-----+-----+
1 row selected

```

CREATE VIEW Command

Use a mutable workspace:

```

0: jdbc:drill:> use dfs.views;
+-----+
| ok | summary |
+-----+
| true | Default schema changed to 'dfs.views' |
+-----+

```

A mutable (or writable) workspace is a workspace that is enabled for “write” operations. This attribute is part of the storage plugin configuration. You can create Drill views and tables in mutable workspaces.

Create a view on a HPE Data Fabric Database binary table

```

0: jdbc:drill:> create or replace view custview as select cast(row_key as
int) as cust_id,
cast(t.personal.name as varchar(20)) as name,
cast(t.personal.gender as varchar(10)) as gender,
cast(t.personal.age as varchar(10)) as age,
cast(t.address.state as varchar(4)) as state,
cast(t.loyalty.agg_rev as dec(7,2)) as agg_rev,
cast(t.loyalty.membership as varchar(20)) as membership

```

```

from maprdb.customers t;
+-----+-----+
|      ok      | summary |
+-----+-----+
| true         | View 'custview' replaced successfully in 'dfs.views' schema |
+-----+-----+
1 row selected

```

Drill provides CREATE OR REPLACE VIEW syntax similar to relational databases to create views. Use the OR REPLACE option to make it easier to update the view later without having to remove it first. Note that the FROM clause in this example must refer to `maprdb.customers`. The HPE Data Fabric Database binary tables are not directly visible to the `dfs.views` workspace.

Unlike a traditional database where views typically are DBA/developer-driven operations, file system-based views in Drill are very lightweight. A view is simply a special file with a specific extension (`.drill`). You can store views even in your local file system or point to a specific workspace. You can specify any query against any Drill data source in the body of the CREATE VIEW statement.

Drill provides a decentralized metadata model. Drill is able to query metadata defined in data sources such as Hive, HBase, and the file system. Drill also supports the creation of metadata in the file system.

Query data from the view:

```
0: jdbc:drill:> select * from custview limit 1;
```

cust_id	name	gender	age	state
10001	"Corrine Mecham"	"FEMALE"	"15-20"	"va"

Once the users know what data is available by exploring it directly from the file system, views can be used as a way to read the data into downstream tools such as Tableau and MicroStrategy for analysis and visualization. For these tools, a view appears simply as a “table” with selectable “columns” in it.

Query Across Data Sources

Continue using `dfs.views` for this query.

Join the customers view and the orders table:

```

0: jdbc:drill:> select membership, sum(order_total) as sales from
hive.orders, custview
where orders.cust_id=custview.cust_id
group by membership order by 2;
+-----+-----+
| membership | sales |
+-----+-----+
| "basic"    | 380665 |
| "silver"   | 708438 |
| "gold"     | 2787682 |
+-----+-----+
3 rows selected

```

In this query, we are reading data from a HPE Data Fabric Database binary table (represented by `custview`) and combining it with the order information in Hive. When doing cross data source queries such as this, you need to use fully qualified table/view names. For example, the orders table is prefixed by “hive,” which

is the storage plugin name registered with Drill. We are not using any prefix for “custview” because we explicitly switched the dfs.views workspace where custview is stored.

NOTE: Note: If the results of any of your queries appear to be truncated because the rows are wide, set the maximum width of the display to 10000:

```
0: jdbc:drill:> !set maxwidth 10000
```

Do not use a semicolon for this SET command.

Join the customers, orders, and clickstream data:

```
0: jdbc:drill:> select custview.membership, sum(orders.order_total) as
sales from hive.orders, custview,
dfs.`/mapr/demo.mapr.com/data/nested/clicks/clicks.json` c
where orders.cust_id=custview.cust_id and
orders.cust_id=c.user_info.cust_id
group by custview.membership order by 2;
```

membership	sales
"basic"	372866
"silver"	728424
"gold"	7050198

3 rows selected

This three-way join selects from three different data sources in one query:

- hive.orders table
- custview (a view of the HBase customers table)
- clicks.json file

The join column for both sets of join conditions is the cust_id column. The views workspace is used for this query so that custview can be accessed. The hive.orders table is also visible to the query.

However, note that the JSON file is not directly visible from the views workspace, so the query specifies the full path to the file:

```
dfs.`/mapr/demo.mapr.com/data/nested/clicks/clicks.json`
```

What's Next

Go to Lesson 3: [Run Queries on Complex Data Types](#)

Lesson 3: Run Queries on Complex Data Types

Goal

This lesson focuses on queries that exercise functions and operators on self-describing data and complex data types. Drill offers intuitive SQL extensions to work with such data and offers high query performance with an architecture built from the ground up for complex data.

Queries in This Lesson

Now that you have run ANSI SQL queries against different tables and files with relational data, you can try some examples including complex types.

- Access directories and subdirectories of files in a single SELECT statement.
- Demonstrate simple ways to access complex data in JSON files.
- Demonstrate the `repeated_count` function to aggregate values in an array.

Query Partitioned Directories

You can use special variables in Drill to refer to subdirectories in your workspace path:

- `dir0`
- `dir1`
- ...

Note that these variables are dynamically determined based on the partitioning of the file system. No up-front definitions are required on what partitions exist.

Set workspace to `dfs.logs`

```
0: jdbc:drill:> use dfs.logs;
+-----+-----+
| ok | summary |
+-----+-----+
| true | Default schema changed to 'dfs.logs' |
+-----+-----+
```

Query logs data for a specific year

```
0: jdbc:drill:> select * from logs where dir0='2013' limit 10;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| dir0 | dir1 | trans_id | date | time | cust_id | device | state | camp_id |
| keywords | prod_id | purch_flag |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 2013 | 11 | 12119 | 11/09/2013 | 02:24:51 | 262 | IOS5 | ny | 0 | chamber |
| 198 | false |
| 2013 | 11 | 12120 | 11/19/2013 | 09:37:43 | 0 | AOS4.4 | il | 2 | outside |
| 511 | false |
| 2013 | 11 | 12134 | 11/10/2013 | 23:42:47 | 60343 | IOS5 | ma | 4 | and |
| 421 | false |
| 2013 | 11 | 12135 | 11/16/2013 | 01:42:13 | 46762 | AOS4.3 | ca | 4 |
| here's | 349 | false |
| 2013 | 11 | 12165 | 11/26/2013 | 21:58:09 | 41987 | AOS4.2 | mn | 4 | he |
| 271 | false |
| 2013 | 11 | 12168 | 11/09/2013 | 23:41:48 | 8600 | IOS5 | in | 6 | i |
| 459 | false |
| 2013 | 11 | 12196 | 11/20/2013 | 02:23:06 | 15603 | IOS5 | tn | 1 | like |
| 324 | false |
| 2013 | 11 | 12203 | 11/25/2013 | 23:50:29 | 221 | IOS6 | tx | 10 | if |
| 323 | false |
| 2013 | 11 | 12206 | 11/09/2013 | 23:53:01 | 2488 | AOS4.2 | tx | 14 |
| unlike | 296 | false |
| 2013 | 11 | 12217 | 11/06/2013 | 23:51:56 | 0 | AOS4.2 | tx | 9 | can't |
| 54 | false |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
```

This query constrains files inside the subdirectory named 2013. The variable `dir0` refers to the first level down from logs, `dir1` to the next level, and so on. So this query returned 10 of the rows for February 2013.

Further constrain the results using multiple predicates in the query

```
0: jdbc:drill:> select dir0 as yr, dir1 as mth, cust_id from logs
where dir0='2013' and dir1='8' and device='IOS5' and purch_flag='true'
order by `date`;
+-----+-----+-----+
| yr | mth | cust_id |
+-----+-----+-----+
| 2013 | 8 | 4 |
| 2013 | 8 | 521 |
| 2013 | 8 | 1 |
| 2013 | 8 | 2 |
| 2013 | 8 | 4 |
| 2013 | 8 | 549 |
| 2013 | 8 | 72827 |
| 2013 | 8 | 38127 |
...
```

This query returns a list of customer IDs for people who made a purchase via an IOS5 device in August 2013.

Return monthly counts per customer for a given year

```
0: jdbc:drill:> select cust_id, dir1 month_no, count(*) month_count from
logs
where dir0=2014 group by cust_id, dir1 order by cust_id, month_no limit 10;
+-----+-----+-----+
| cust_id | month_no | month_count |
+-----+-----+-----+
| 0 | 1 | 143 |
| 0 | 2 | 118 |
| 0 | 3 | 117 |
| 0 | 4 | 115 |
| 0 | 5 | 137 |
| 0 | 6 | 117 |
| 0 | 7 | 142 |
| 0 | 8 | 19 |
| 1 | 1 | 66 |
| 1 | 2 | 59 |
+-----+-----+-----+
10 rows selected
```

This query groups the aggregate function by customer ID and month for one year: 2014.

Query Complex Data

Drill provides some specialized operators and functions that you can use to analyze nested data natively without transformation. If you are familiar with JavaScript notation, you will already know how some of these extensions work.

Set the workspace to dfs.clicks

```
0: jdbc:drill:> use dfs.clicks;
+-----+-----+
| ok | summary |
+-----+-----+
| true | Default schema changed to 'dfs.clicks' |
+-----+-----+
```

Explore clickstream data

```
0: jdbc:drill:> select * from `clicks/clicks.json` limit 5;
+-----+-----+-----+-----+-----+
| trans_id | date   | time   | user_info | trans_info |
+-----+-----+-----+-----+-----+
| 31920    | 2014-04-26 | 12:17:12 | {"cust_id":22526,"device":"IOS5","state":"il"} | {"prod_id":
[174,2],"purch_flag":"false"} |
| 31026    | 2014-04-20 | 13:50:29 | {"cust_id":16368,"device":"AOS4.2","state":"nc"} | {"prod_id":
[],"purch_flag":"false"} |
| 33848    | 2014-04-10 | 04:44:42 | {"cust_id":21449,"device":"IOS6","state":"oh"} | {"prod_id":
[582],"purch_flag":"false"} |
| 32383    | 2014-04-18 | 06:27:47 | {"cust_id":20323,"device":"IOS5","state":"oh"} | {"prod_id":
[710,47],"purch_flag":"false"} |
| 32359    | 2014-04-19 | 23:13:25 | {"cust_id":15360,"device":"IOS5","state":"ca"} | {"prod_id":
[0,8,170,173,1,124,46,764,30,711,0,3,25],"purch_flag":"true"} |
+-----+-----+-----+-----+-----+
```

Note that the `user_info` and `trans_info` columns contain nested data: arrays and arrays within arrays. The following queries show how to access this complex data.

Unpack the user_info column

```
0: jdbc:drill:> select t.user_info.cust_id as custid, t.user_info.device as
device,
t.user_info.state as state
from `clicks/clicks.json` t limit 5;
+-----+-----+-----+
| custid | device | state |
+-----+-----+-----+
| 22526  | IOS5   | il    |
| 16368  | AOS4.2 | nc    |
| 21449  | IOS6   | oh    |
| 20323  | IOS5   | oh    |
| 15360  | IOS5   | ca    |
+-----+-----+-----+
```

This query uses a simple `table.column.column` notation to extract nested column data. For example:

```
t.user_info.cust_id
```

where `t` is the table alias provided in the query, `user_info` is a top-level column name, and `cust_id` is a nested column name.

The table alias is required; otherwise column names such as `user_info` are parsed as table names by the SQL parser.

Unpack the trans_info column

```
0: jdbc:drill:> select t.trans_info.prod_id as prodid,
t.trans_info.purch_flag as
purchased
from `clicks/clicks.json` t limit 5;
+-----+-----+
| prodid | purchased |
+-----+-----+
```

```
| [174,2] | false |
| [] | false |
| [582] | false |
| [710,47] | false |
| [0,8,170,173,1,124,46,764,30,711,0,3,25] | true |
+-----+
5 rows selected
```

Note that this result reveals that the `prod_id` column contains an array of IDs (one or more product ID values per row, separated by commas). The next step shows how you to access this kind of data.

Query Arrays

Now use the `[ n ]` notation, where `n` is the position of the value in an array, starting from position 0 (not 1) for the first value. You can use this notation to write interesting queries against nested array data.

For example:

```
trans_info.prod_id[0]
```

refers to the first value in the nested `prod_id` column and

```
trans_info.prod_id[20]
```

refers to the 21st value, assuming one exists.

Find the first product that is searched for in each transaction:

```
0: jdbc:drill:> select t.trans_id, t.trans_info.prod_id[0] from `clicks/
clicks.json` t limit 5;
+-----+-----+
| trans_id | EXPR$1 |
+-----+-----+
| 31920    | 174    |
| 31026    | null   |
| 33848    | 582    |
| 32383    | 710    |
| 32359    | 0      |
+-----+-----+
5 rows selected
```

For which transactions did customers search on at least 21 products?

```
0: jdbc:drill:> select t.trans_id, t.trans_info.prod_id[20]
from `clicks/clicks.json` t
where t.trans_info.prod_id[20] is not null
order by trans_id limit 5;
+-----+-----+
| trans_id | EXPR$1 |
+-----+-----+
| 10328    | 0      |
| 10380    | 23     |
| 10701    | 1      |
| 11100    | 0      |
| 11219    | 46     |
+-----+-----+
5 rows selected
```

This query returns transaction IDs and product IDs for records that contain a non-null product ID at the 21st position in the array.

Return clicks for a specific product range:

```
0: jdbc:drill:> select * from (select t.trans_id, t.trans_info.prod_id[0]
as prodid,
t.trans_info.purch_flag as purchased
from `clicks/clicks.json` t) sq
where sq.prodid between 700 and 750 and sq.purchased='true' order by
sq.prodid;
+-----+-----+-----+
| trans_id | prodid | purchased |
+-----+-----+-----+
| 21886 | 704 | true |
| 20674 | 708 | true |
| 22158 | 709 | true |
| 34089 | 714 | true |
| 22545 | 714 | true |
| 37500 | 717 | true |
| 36595 | 718 | true |
...
```

This query assumes that there is some meaning to the array (that it is an ordered list of products purchased rather than a random list).

Perform Operations on Arrays**Rank successful click conversions and count product searches for each session:**

```
0: jdbc:drill:> select t.trans_id, t.`date` as session_date,
t.user_info.cust_id as
cust_id, t.user_info.device as device, repeated_count(t.trans_info.prod_id)
as
prod_count, t.trans_info.purch_flag as purch_flag
from `clicks/clicks.json` t
where t.trans_info.purch_flag = 'true' order by prod_count desc;
+-----+-----+-----+-----+-----+-----+
| trans_id | session_date | cust_id | device | prod_count | purch_flag |
+-----+-----+-----+-----+-----+-----+
| 37426 | 2014-04-06 | 18709 | IOS5 | 34 | true |
| 31589 | 2014-04-16 | 18576 | IOS6 | 31 | true |
| 11600 | 2014-04-07 | 4260 | AOS4.2 | 28 | true |
| 35074 | 2014-04-03 | 16697 | AOS4.3 | 27 | true |
| 17192 | 2014-04-22 | 2501 | AOS4.2 | 26 | true |
...
```

This query uses a Drill SQL extension, the `repeated_count` function, to get an aggregated count of the array values. The query returns the number of products searched for each session that converted into a purchase and ranks the counts in descending order. Only clicks that have resulted in a purchase are counted.

Store a Result Set in a Table for Reuse and Analysis

To facilitate additional analysis on this result set, you can easily and quickly create a Drill table from the results of the query.

Continue to use the `dfs.clicks` workspace

```
0: jdbc:drill:> use dfs.clicks;
+-----+-----+-----+-----+-----+-----+
| trans_id | session_date | cust_id | device | prod_count | purch_flag |
+-----+-----+-----+-----+-----+-----+
| 37426 | 2014-04-06 | 18709 | IOS5 | 34 | true |
| 31589 | 2014-04-16 | 18576 | IOS6 | 31 | true |
| 11600 | 2014-04-07 | 4260 | AOS4.2 | 28 | true |
| 35074 | 2014-04-03 | 16697 | AOS4.3 | 27 | true |
| 17192 | 2014-04-22 | 2501 | AOS4.2 | 26 | true |
...
```

```
| ok | summary |
+-----+
| true | Default schema changed to 'dfs.clicks' |
+-----+
```

Return product searches for high-value customers:

```
0: jdbc:drill:0: jdbc:drill:> select o.cust_id, o.order_total,
t.trans_info.prod_id[0] as prod_id
from
hive.orders as o
join `clicks/clicks.json` t
on o.cust_id=t.user_info.cust_id
where o.order_total > (select avg(inord.order_total)
                        from hive.orders inord
                        where inord.state = o.state);
```

cust_id	order_total	prod_id
1328	73	26
1328	146	26
1328	56	26
1328	91	26
1328	74	26
...		

```
107,482 rows selected (14.863 seconds)
```

This query returns a list of products that are being searched for by customers who have made transactions that are above the average in their states.

Materialize the result of the previous query:

```
0: jdbc:drill:0: jdbc:drill:> create table product_search as select
o.cust_id, o.order_total, t.trans_info.prod_id[0] as prod_id
from
hive.orders as o
join `clicks/clicks.json` t
on o.cust_id=t.user_info.cust_id
where o.order_total > (select avg(inord.order_total)
                        from hive.orders inord
                        where inord.state = o.state);
```

Fragment	Number of records written
0_0	107482

```
1 row selected
```

This example uses a CTAS statement to create a table based on a correlated subquery that you ran previously. This table contains all of the rows that the query returns (107,482) and stores them in the format specified by the storage plugin (Parquet format in this example). You can create tables that store data in csv, parquet, and json formats.

Query the new table to verify the row count

```
0: jdbc:drill:> select count(*) from product_search;
```

EXPR\$0
107482

```
| 107482 |
+-----+
1 row selected
```

This example simply checks that the CTAS statement worked by verifying the number of rows in the table.

Find the storage file for the table

```
[root@maprdemo product_search]# cd /mapr/demo.mapr.com/data/nested/
product_search
[root@maprdemo product_search]# ls -la
total 451
drwxr-xr-x. 2 mapr mapr      1 Sep 15 13:41 .
drwxr-xr-x. 4 root root      2 Sep 15 13:41 ..
-rwxr-xr-x. 1 mapr mapr 460715 Sep 15 13:41 0_0_0.parquet
```

Note that the table is stored in a file called `0_0_0.parquet`. This file is stored in the location defined by the `dfs.clicks` workspace:

```
"location": "/mapr/demo.mapr.com/data/nested"
```

with a subdirectory that has the same name as the table you created.

Summary

This tutorial introduced Drill and its ability to run ANSI SQL queries against various data sources, including Hive tables, HPE Data Fabric Database binary tables, and file system directories. The tutorial also showed how to work with and manipulate complex and multi-structured data commonly found in Hadoop/NoSQL systems.

Now that you are familiar with different ways to access the sample data with Drill, you can try writing your own queries against your own data sources. Refer to the [Apache Drill documentation](#) for more information.

Drill-on-YARN

You can install and run Drill under Warden or you can install and run Drill under YARN. [YARN \(Yet Another Resource Negotiator\)](#) is a cluster management tool that automates the resource sharing process in a cluster.

NOTE: The [default security feature](#) introduced in 6.0 is not supported with Drill-on-YARN.

The following sections provide information about Drill-on-YARN, including overview material, installation and configuration instructions, and additional information related to Drill-on-YARN:

Drill-on-YARN Overview

Running Drill as a YARN application (Drill-on-YARN) enables Drill to work alongside other applications, such as Hadoop and Spark, in a YARN-managed cluster. If you are currently running Drill under Warden, you can upgrade Drill and continue to run Drill under Warden, or you can migrate Drill to run under YARN. See [Migrate Drill to Run Under YARN](#) for instructions.

YARN assigns resources, such as memory and CPU, to applications in the cluster and eliminates the manual steps associated with installation and resource allocation for stand-alone applications in a multi-tenant environment. YARN automatically deploys (localizes) the Drill software onto each Drill node and manages the Drill cluster. Drill becomes a long-running application with YARN. You can monitor the Drill-on-YARN cluster using the Application Master web UI.

Resource Usage

By design, Drill aggressively uses all of the resources available to run queries at optimal speed. When Drill runs under YARN, you must inform YARN of the resources that Drill needs. The resource settings

are descriptive, not proscriptive. Drill does not limit itself to the YARN settings, instead the YARN settings inform YARN of the resources that Drill will consume so that YARN does not over-allocate those resources to other tasks.

YARN manages CPU, memory, and disks. YARN calls settings for memory and CPU “vcores.” You configure Drill’s memory and then inform YARN of the Drill configuration. Drill uses all available disk I/O and CPU.

Components

Several software components work together to run Drill as a YARN application. Drill, YARN, and the Drill-on-YARN application collectively provide the components required to run Drill under YARN.

The following table lists the software components with their descriptions:

Software	Component	Description
YARN	Resource Manager	The Resource Manager manages the set of applications running on the cluster. Each cluster must have one Resource Manager.
	Node Manager	The Node Manager manages the application tasks running on a particular node. Each node in a cluster must have one Node Manager.
Drill	Drillbit	A Drillbit is the Drill daemon software that YARN runs on each node in the cluster. See Drill Query Execution . The Drillbit process on the node acts as the application task.
	Client	A client, such as JDBC, ODBC, or SQLLine sends queries to a Drillbit. The client uses ZooKeeper to discover a Drillbit that the client treats as the Foreman. See Drill Clients .
	Drill distribution archive	The Drill distribution archive is a Drill distribution .tar.gz file included with the Drill installation. Drill-on-YARN uploads this archive to the distributed filesystem (DFS). YARN downloads (localizes) the file to each worker node.
ZooKeeper	ZooKeeper	ZooKeeper is the service that tracks the available set of Drillbit processes. The Foreman for a query uses ZooKeeper to identify the set of available drill nodes that can run the query. See Drill Query Execution .
Drill-on-YARN Application	Application Master (AM)	The Application Manager requests containers from the Resource Manager and launches Drillbits using those containers. The AM monitors Drillbits, detects failures, and restarts failed Drillbits. The AM also provides a web UI to manage the Drill cluster.

	Drill-on-YARN client	The Drill-on-YARN client is a command-line program that starts, stops, and monitors the Drill cluster. The client provides the information that YARN needs to start the Application Master. The client can run on any machine that has both the Drill and YARN client software. The client does not have to be part of the YARN cluster.
	drill-on-yarn.conf	The drill-on-yarn.conf configuration file provides the information that Drill-on-YARN needs to manage the Drill cluster. This file is separate from the configuration files for Drill itself.

Component Workflow

Running Drill as a YARN application is mostly an automated process carried out by the Drill and YARN components. After an administrator installs, configures, and launches Drill from the Drill-on-YARN client, YARN deploys (localizes) Drill on to designated nodes and starts the Drill process on each node.

The following diagram shows the workflow between the components in a cluster with the steps that Drill and YARN complete to deploy and run Drill as a YARN application:

Configuring Drill to Run Under YARN

To run Drill under YARN, you must have the YARN version of Drill installed on the node designated as the Drill-on-YARN client. If you have not already planned your cluster and installed the YARN-ready version of

Drill, see [Install Drill to Run Under YARN](#) and then return to this topic to configure Drill to run as a YARN application.

Configuring Drill to run under YARN requires modifications to Drill, Drill-on-YARN, and YARN configuration files. The following sections provide the information needed to make the changes to the configuration files, as well as information about how to launch Drill under YARN and validate the cluster configuration and status of the Drill nodes.

Complete the following steps to configure Drill to run under YARN, launch Drill as a YARN application, and validate the cluster:

Before You Configure Drill to Run Under YARN

Provides the steps required to repackage the Drill-on-YARN archive.

During Drill-on-YARN installation, the system fails to upload the Drill archive because JNI finds a mismatch for Java and native libraries. If you install and try to start Drill-on-YARN using the `mapr-drill-yarn` package, the system returns an error.

To prevent this issue from occurring, complete the following steps to repackage the Drill-on-YARN archive:

1. Install Drill-on-YARN, as described in [Installing Drill to Run Under YARN](#) on page 293, but do not configure or start Drill-on-YARN.

2. Create a file named `recreate_archive.sh` with the following information:

TIP: You can create and run this file in any location you choose.

```
read -p "This operation will recreate drill.tar.gz in drill home
directory. Continue? " -n 1 -r
echo
if [[ ! $REPLY =~ ^[Yy]$ ]]
then
    exit 1
fi

drillHome="/opt/mapr/drill/drill-$(cat /opt/mapr/drill/drillversion)"
hadoopHome="/opt/mapr/hadoop/hadoop-$(cat /opt/mapr/hadoop/
hadoopversion)"

hbaseJar="$(ls /opt/mapr/lib/mapr-hbase-*-mapr.jar)"
maprWebJar="$(ls /opt/mapr/lib/mapr-security-*-mapr.jar)"
maprdbJar="$(ls /opt/mapr/lib/maprdb-[0-9].[0-9].[0-9].[0-9]
[0-9]-mapr.jar)"
mapredJar="$(ls /opt/mapr/lib/maprdb-mapreduce-*-mapr.jar)"
maprfsJar="$(ls /opt/mapr/lib/maprfs-[0-9].[0-9].[0-9].[0-9]
[0-9]-mapr.jar)"
jerseyClientJar="$(ls ${hadoopHome}/share/hadoop/yarn/lib/
jersey-client-*.jar)"
jerseyCoreJar="$(ls ${hadoopHome}/share/hadoop/yarn/lib/
jersey-core-*.jar)"

echo "Drop old mapr jars from ${drillHome}/jars/3rdparty/"
rm -f ${drillHome}/jars/3rdparty/mapr-hbase*
rm -f ${drillHome}/jars/3rdparty/mapr-security-web-*
rm -f ${drillHome}/jars/3rdparty/maprdb-*
rm -f ${drillHome}/jars/3rdparty/maprfs-*

echo "Copy new jars from /opt/mapr/lib/"
cp ${hbaseJar} ${drillHome}/jars/3rdparty/
[ $? == 0 ] && echo "${hbaseJar} has been copied"
cp ${maprWebJar} ${drillHome}/jars/3rdparty/
[ $? == 0 ] && echo "${maprWebJar} has been copied"
cp ${maprdbJar} ${drillHome}/jars/3rdparty/
[ $? == 0 ] && echo "${maprdbJar} has been copied"
cp ${mapredJar} ${drillHome}/jars/3rdparty/
[ $? == 0 ] && echo "${mapredJar} has been copied"
cp ${maprfsJar} ${drillHome}/jars/3rdparty/
[ $? == 0 ] && echo "${maprfsJar} has been copied"

echo "Copy jersey jars from hadoop for timeline client"
cp ${jerseyClientJar} ${drillHome}/jars/3rdparty/
[ $? == 0 ] && echo "${jerseyClientJar} has been copied"
cp ${jerseyCoreJar} ${drillHome}/jars/3rdparty/
[ $? == 0 ] && echo "${jerseyCoreJar} has been copied"

if [ -f ${drillHome}/drill.tar.gz ]; then
    rm -f ${drillHome}/drill.tar.gz
    echo "${drillHome}/drill.tar.gz has been dropped"
fi

tempDir=drill-$(date +%s)

mkdir /tmp/$tempDir
[ $? == 0 ] && echo "Created temporary directory ${tempDir}"

cd /tmp/$tempDir
```

```
mkdir drill
[ $? == 0 ] && echo "Created drill directory"

cp -r ${drillHome}/* ./drill/
echo "${drillHome} copied to drill directory"

tar -czf drill.tar.gz ./drill
echo "Created new drill archive"

cp drill.tar.gz ${drillHome}/
echo "drill.tar.gz copied to ${drillHome}"

rm -rf /tmp/$tempDir
echo -e "\033[0;32mDONE.\033[0m"
```

3. Issue the following command to run the script:

```
./recreate_archive.sh
```

When the script runs, a prompt appears:

```
This operation will recreate drill.tar.gz in drill home directory.
Continue?
```

Reply with y to allow the script to update the JAR files in Drill-on-YARN.

You should see output similar to the following (versions may differ):

```
ls: cannot access '/opt/mapr/hadoop/hadoop-3.3.5/share/hadoop/yarn/lib/
jersey-core-*.jar': No such file or directory
Drop old mapr jars from /opt/mapr/drill/drill-1.20.3/jars/3rdparty/

DONE.
```

4. Continue to [Step 1: Configure Drill](#) on page 4706.

Step 1: Configure Drill

Drill configuration under Drill-on-YARN differs from Drill configuration under Warden. You must create a site directory to contain the site-specific files for Drill. Drill-on-YARN copies the site directory to every node so that each node has the configuration settings. Having a site directory also simplifies upgrades because

you can just delete the old Drill distribution and install the new one while the site-specific files remain unchanged in the site directory.

The `drill-env.sh` file contains only custom configurations. Data Fabric-specific configuration settings reside in `distrib-env.sh`, a file separate from the site-specific settings. When you migrate an existing Drill installation to run under YARN, you must modify the `drill-env.sh` to remove the Drill and Data Fabric settings, leaving only your site-specific settings.

When you finish configuring Drill, use the site directory to test Drill, including starting, checking status, and stopping Drill.

NOTE: If you installed the `mapr-drill-yarn` package on nodes other than the Drill-on-YARN client in order to make `SQLLine` accessible to users, the site directory must be accessible from all nodes. You can copy the configurations across all the nodes, as you did when you ran Drill under the Warden service. Alternatively, you can put the site directory in a shared filesystem `nfs` mount to extend the configuration. When users launch `SQLLine`, they should provide the ZooKeeper connection string to launch Drill.

Create the Site Directory

To create the site directory, complete the following steps as the user that installed Drill and will run the Drill-on-YARN client application:

1. Create the site directory and an environment variable for the directory:

```
export DRILL_SITE=/opt/mapr/drill/site
mkdir $DRILL_SITE
```

NOTE: The variable is not required. It is used for convenience in the documentation.

2. Change the owner of `$DRILL_SITE` and of the parent directory `/opt/mapr/drill` to the cluster admin user (`mapr` by default).

```
sudo chown mapr:mapr /opt/mapr/drill
sudo chown mapr:mapr /opt/mapr/drill/site
```

3. Copy the `drill-env.sh`, `drill-override.conf`, `drill-on-yarn.conf`, and `distrib-env.sh` files from `$DRILL_HOME/conf/` into the site directory. In the following example, `$DRILL_HOME` is the location of the new Drill installation (usually `/opt/mapr/drill/drill-<version>`).

```
cp $DRILL_HOME/conf/drill-override.conf $DRILL_SITE
cp $DRILL_HOME/conf/drill-env.sh $DRILL_SITE
cp $DRILL_HOME/conf/drill-on-yarn.conf $DRILL_SITE
cp $DRILL_HOME/conf/distrib-env.sh $DRILL_SITE
```

NOTE: Copy any configuration changes from `drill-env.sh` file in the previous Drill installation over to the `drill-env.sh` file in the site directory. Do not include the memory settings when you copy over your previous configurations. These changes must be made in the `drill-on-yarn.conf` file described in Step 3: Configure YARN to Run Drill.

NOTE: Never modify `distrib-env.sh`. The `distrib-env.sh` script contains Data Fabric settings that you should not change. You copy this file to the site directory because it often contains values set during Drill installation. When you upgrade Drill, replace the file with the latest version from `$DRILL_HOME/conf`.

4. If you developed custom code (data sources or user-defined functions), place the Java JAR files in \$DRILL_SITE/jars. If you have code from your prior Drill installation, copy the JAR files from \$PREV_DRILL/jars/3rdparty to \$DRILL_SITE/jars.

```
cp $PREV_DRILL/jars/3rdparty/yourJarName.jar $DRILL_SITE/jars
```

NOTE: Only copy the JAR files that you added. Do not copy JAR files that shipped with the prior Drill version.

5. Add native libraries to the site directory. If you used a native library, such as the JPAM library in prior versions of Drill, place the native libraries in \$DRILL_SITE/lib to enable YARN to automatically copy (localize) them to each node that runs Drill.

```
cp native_libraries $DRILL_SITE/lib
```

Modify the drill-env.sh File

Copy any configuration changes from the drill-env.sh file in the previous Drill installation over to the drill-env.sh file in the site directory. Memory settings under Drill-on-YARN are now part of the drill-on-yarn.conf file. Modify the memory settings in \$DRILL_SITE/drill-env.sh, as shown below, to ensure that the Drill memory settings match the amount of memory that Drill-on-YARN requires.

To modify drill-env.sh, complete the following steps:

1. Review each line in \$PREV_DRILL/conf/drill-env.sh for settings you added, and copy them into the new \$DRILL_SITE/drill-env.sh file.

NOTE: If you do not recall whether you customized settings, you can compare your file with the original version of drill-env.sh that shipped with the prior Drill version.

2. Locate the following lines in drill-env.sh and note the values:

```
DRILL_MAX_DIRECT_MEMORY="<value>"
DRILL_HEAP="<value>"
```

Replace those lines with the following lines, substituting the values in the new lines with the values from the old lines:

```
export DRILL_MAX_DIRECT_MEMORY=${DRILL_MAX_DIRECT_MEMORY:- "<value>"}
export DRILL_HEAP=${DRILL_HEAP:- "<value>"}
```

NOTE: If you do not intend to run Drill outside of YARN, you can remove the two lines shown above from drill-env.sh.

NOTE: If you do not make this change, Drill ignores the memory settings in the drill-on-yarn.conf file. If you are installing Drill fresh, and do not have an existing file, you can skip this step. Files in Drill 1.8 and later have the correct format.

NOTE: When you install Drill, the Installer automatically adds the HADOOP_HOME variable, which points the current Data Fabric-provided Hadoop to your distrib-env.sh. If HADOOP_HOME is located elsewhere, change this location in drill-env.sh

Use the Site Directory to Test Drill

You will use the site directory each time you start Drill using the `--site` or `--config` option. Use the option to verify that the configuration works by starting Drill as a stand-alone service on a single node.

```
drillbit.sh --site $DRILL_SITE start
```

Wait a few seconds and then verify that Drill continues to run:

```
drillbit.sh --site $DRILL_SITE status
```

You can also use the Drill Web Console for the Drillbit to verify that Drill has the proper settings. Once satisfied that the configuration is connect, stop Drill:

```
drillbit.sh --site $DRILL_SITE stop
```

NOTE: If you run a Drillbit with the `--site` (`--config`) option and you want to use SQLLine, you must add the option to SQLLine:

```
sqlline --site $DRILL_SITE
```

TIP: If you find that specifying the `--site` option becomes tedious, you can set the `DRILL_CONF_DIR` variable in your environment:

```
export DRILL_CONF_DIR="$DRILL_SITE"
drillbit.sh start
```

Step 2: Configure Drill-on-YARN

To configure Drill to run as a YARN application, modify the `$DRILL_SITE/drill-on-yarn.conf` cluster configuration file to suit the needs of your cluster. This file is a “starter” configuration file that corresponds to the simplest Drill cluster. The `drill-on-yarn.conf` file is in the same [HOCON](#) format as `drill-override.conf`.

Consult the `$DRILL_HOME/conf/drill-on-yarn-example.conf` file as an example. However, do not just copy the example file. Instead, copy only the specific configuration settings that you need; the others will automatically take the Drill-defined default values.

NOTE: Make sure that resources can accommodate the Drill memory, CPU, and disk requirements.

The following sections list the configuration settings required to run Drill under YARN:

Drill Memory Settings

The following configuration sets the Java heap size and amount of direct memory the node can allocate to Drill:

```
drillbit: { heap: "<value>" max-direct-memory: "<value>" }
```

When you add the configuration, use the same values set in the following parameters of the `drill-env.sh` file, if you did not remove these lines when you modified `drill-env.sh`:

```
export DRILL_MAX_DIRECT_MEMORY=${DRILL_MAX_DIRECT_MEMORY:-"<value>"}
export DRILL_HEAP=${DRILL_HEAP:-"<value>"}
```

Drill-on-YARN copies these values into the environment variables when launching each Drillbit. Drill also uses additional JVM memory. For example, Drill uses a code cache to hold classes generated at runtime. The default size of the cache is 1 GB:

```
drillbit: { code-cache: "1G" }
```

Typically, you do not need to change the code cache size, but you must account for it when computing the YARN container size.

YARN Container Size

The following configuration sets the YARN container size required to run Drill as a YARN application.

```
drillbit: {
  memory-mb: 14336
}
```

The default value is 14GB. Typically, this size is the sum of the heap and direct memory. However, if you use custom libraries that perform their own memory allocation, or launch sub-processes, you must account for that memory usage as well. Note that YARN memory is expressed in MB. To compute the container size, start with the values used for the heap, direct memory, and code cache settings, as shown in the following example:

```
drillbit: {
  heap: "4G"
  max-direct-memory: "8G"
  code-cache: "1G"
  memory-mb: 14336
}
```

The values shown above are the Drill defaults. You may use larger values. Although the three values account for the bulk of Drill memory, the JVM itself also has a certain overhead. Assume that the overhead is about 1 GB, though the amount varies depending on the workload.

Add the four values together to get a memory requirement in GB.

```
Total memory = 8G + 4G + 1G + 1G = 14G
```

YARN sizes containers in megabytes. Convert GB to MB:

```
Container size = 14G * 1024 = 14336 MB
```

Set this size in drill-on-yarn.conf:

```
drillbit: { memory-mb: 14336 }
```

CPU

The following configuration sets the CPU to allocate to Drill:

```
drillbit: { vcores: <value> }
```

Drill is a CPU-intensive operation and greatly benefits from each additional core. YARN does not limit the number of cores used by an application. Rather, this number reports to YARN the average CPU usage of Drill so that YARN can use the number when deciding how many other applications to run on the same node.

Drillbit Cluster Configuration

The following configuration sets the cluster group:

```
cluster: [ { name: "drillbits" type: "basic" count: 1 } ]
```

Drill-on-YARN uses the concept of a “cluster group” of Drillbits to describe the set of drillbits to launch. Currently, only the “basic” type of group is supported. A basic group launches drillbits anywhere in the YARN cluster where a container is available. For a basic group, specify the group type and the number of drillbits to launch.

NOTE: The syntax says that cluster is a list that contains cluster group objects contained in braces. Drill currently supports just one group.

The name is optional. It appears in the Application Master web UI. Type must be set to “basic.” Set the count to the number of hosts on which Drill is to run at launch time. You can resize the Drill cluster after the cluster is launched.

YARN Queue Labels

The following configuration sets the YARN queue labels that identify the cluster nodes that run Drill:

```
yarn: { queue: "<queue_name>" }
```

The distribution of YARN provides queue labels for assigning YARN applications to specific queues. See [Label-Based Scheduling for YARN Applications](#). You can use queue labels with Drill to identify the YARN queue that should run Drill.

To use queue labels, complete the following steps:

1. Create a node label.
2. Assign the label to the nodes that are to run Drill.
3. Create a Drill-specific queue that uses the node label.
4. Configure Drill-on-YARN to use the queue.

Suppose you create a queue called “drill.” Setting the following configuration causes Drill-on-YARN to launch through the drill queue:

```
yarn: { queue: "drill" }
```

Set queue to the name of your choice. When Drill-on-YARN launches, both the Application Master and drillbits run only on nodes with the same node label as the queue.

DFS Location

The following configuration sets the dfs location:

```
dfs: { app-dir: "/user/drill" }
```

Drill copies the archive in to the filesystem in a location you provide. The default is /user/drill, however you can specify a different location. You do not have to specify the file system connection information; this information is automatically defined.

Step 3: Configure YARN to Run Drill

YARN default settings are optimized for MapReduce applications. MapReduce applications use a limited amount of memory; however, Drill is long-running and consumes a significant amount of resources. Adjust the YARN memory configuration to allow YARN to allocate containers large enough to run Drill. Exclude the

YARN container directory from `systemd-tmpfiles` to prevent `systemd-tmpfiles` from removing Drill's container files while Drill runs.

Increase Maximum Container Size

YARN provides a number of parameters to control the amount of resources available to applications. The Data Fabric distribution of YARN sets most of these parameters automatically, except for the maximum container size, which is left at the Apache YARN default of 8 GB. Typical Drill configurations use significantly more memory. Therefore, you must increase the YARN maximum container size on each node to suit the needs of Drill. You can use the YARN Resource Manager web UI to determine the amount of memory available on each node.

NOTE: YARN resource requirements match the Drill resource requirements.

To increase the maximum container size, determine the required container size from the Drill setting in `drill-on-yarn.conf`, which you previously set in step 2:

```
drillbit: {
  memory-mb: 14336
}
```

Use this number to set the `yarn.scheduler.maximum-allocation-mb` parameter in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop.<version>`, substituting the number of the version you have installed.

Edit `yarn-site.xml` to add the following:

```
<property>
  <name>yarn.scheduler.maximum-allocation-mb</name>
  <value>14336</value>
  <description>Set to allow Drill containers 14G.</description>
</property>
```

NOTE: You must update this configuration on every YARN node.

Restart the YARN Resource Manager to pick up change, and use the YARN Resource Manager UI to verify that the maximum container size shows the new value.

Exclude the YARN Container Directory from systemd-tmpfiles

The system puts the YARN Node Manager container files in the `/tmp` directory. Most system administrators configure `systemd-tmpfiles` to periodically remove files in `/tmp`. Since Drill-on-YARN is a long-running YARN application, `systemd-tmpfiles` can remove Drill's container files while Drill runs. If this occurs, you must manually shut down the Drill cluster because `systemd-tmpfiles` will have removed the pid file that YARN needs to manage Drill.

You can prevent `systemd-tmpfiles` from cleaning up Drill's container files by adding a new configuration file to `/etc/tmpfiles.d/`, for example `/etc/tmpfiles.d/exclude-nm-local-dir.conf`, with the following configuration:

```
x /tmp/hadoop-mapr/nm-local-dir/*
```

NOTE: This configuration prevents `systemd-tmpfiles` from cleaning the `/nm-local-dir` directory when cleaning `/tmp`.

Example

```
$ cat /etc/tmpfiles.d/exclude-nm-local-dir.conf
x /tmp/hadoop-mapr/nm-local-dir/*
```

Step 4: Launch Drill Under YARN

Now that the Drill and YARN configuration is complete, you can issue the start command from the Drill-on-YARN client to launch Drill under YARN. Launching Drill-on-YARN from the client starts Drill and brings Drill up on other nodes.

Issuing the start command starts the YARN Application Master, which then works with YARN to start the Drillbits. The Application Master provides a web UI to monitor the cluster.

NOTE: To simplify debugging, you can set the cluster size to a single node. Once you confirm that a single node works, increase the node count.

Launch Drill under YARN as the mapr user. For example, if you installed Drill as mapr launch Drill as the mapr user.

NOTE: If you launch Drill as root and the system returns an error failing the launch attempt, launch Drill as a user with permissions, such as mapr.

Issue the following command to start Drill under YARN:

```
$DRILL_HOME/bin/drill-on-yarn.sh --site $DRILL_SITE start
```

NOTE: To run SQLLine, you must also add the --site option:

```
$DRILL_HOME/bin/sqlline --site $DRILL_SITE
```

TIP: To avoid typing the site argument each time you launch Drill under YARN, set an environment variable:

```
export DRILL_CONF_DIR=$DRILL_SITE
$DRILL_HOME/bin/drill-on-yarn.sh start
```

After you issue the start command, a number of lines describing the start-up process print. The tool automatically archives and uploads the site directory, which YARN copies (along with the Drill software) onto each node. A URL that includes both the host and the port number displays. Enter the URL in a web browser to access the Application Master web UI.

NOTE: When you launch Drill from the Drill-on-YARN client, the Application Master can come up on any node. Save the provided URL to share with other users so they can also access the Application Master. Alternatively, you can run the status command to see the URL or go to the YARN Resource Manager UI to get the link.

See [Drill-on-YARN Command Line Tool](#) for additional commands, including stop, status, and resize. See [Application Master Web UI](#) for cluster monitoring information.

Step 5: Validate Cluster Configuration and Status

The Drill-on-YARN command line tool prints a URL, for the Drill Application Master process, that you can use to monitor the cluster. The Drillbits should be up and running, unless the upload or launch failed.

Failed upload

If the upload fails, the most likely reason is that the HADOOP_HOME variable is not set, or the user launching Drill-on-YARN does not have permission

Failed launch

to create or write to the DFS location set in the Drill-on-YARN configuration file.

If the launch fails, verify that the YARN maximum container size was set to be at least as large as the Drill container size and that YARN can provide the number of vcores and disks you have requested for Drill.

Monitor Cluster Activity

When the cluster launches successfully, you can verify the status of the components in the Drill cluster from the command line or you can copy the Application Master URL into your browser to use the Application Master web UI.

To check the status from the command line, issue the following command:

```
$DRILL_HOME/bin/drill-on-yarn.sh --site $DRILL_SITE status
```

- Verify that the Drillbits are in the Running state (or transition to that state after a few moments.) If the Drillbits remain in the Requesting state, the likely cause is that YARN cannot provide a container of the requested size. You can access this information on the Drillbits page in the Application Master web UI.
- Verify that the Application Master has correctly picked up the YARN-related configuration from drill-override.conf and drill-on-yarn.conf. You can access this information on the Configuration page in the Application Master web UI.
- Verify that the Application Master is running. The Drill Application Master uses ZooKeeper to verify that only one Application Master runs per Drill cluster. The Application Master fails if ZooKeeper is down, is configured incorrectly in drill-override.conf, or if another Application Master is running for the same cluster.
- Verify that the configurations in drill-override.conf are correct if there are Drillbit failures. Drill-on-YARN detects Drillbit failures and retries each Drillbit a few times. If the Drillbit continues to fail, the node is black-listed for that run of Drill-on-YARN. You can see failures in the History page of the web UI. If your Drillbits fail, the most likely reason is misconfiguration within drill-override.conf. Use YARN to locate and view the Drill logs for the failed container.

Resize the Cluster

If the cluster works well for a single node, you can increase the number of nodes.

NOTE: In the Drill 1.8 release, adding nodes can be done while users run queries. However, removing nodes from the cluster causes queries to fail, and so should only be done when the cluster is idle.

To make a permanent change, modify the cluster size in drill-on-yarn.conf:

```
cluster: [
  {
    ...
    count: 5
  }
]
```

You can also resize the cluster dynamically. To add two nodes from the command line:

```
$DRILL_HOME/bin/drill-on-yarn.sh --site $DRILL_SITE resize +2
```

To set the cluster size to a total of five nodes:

```
$DRILL_HOME/bin/drill-on-yarn.sh --site $DRILL_SITE resize 5
```

To remove one of the nodes:

```
$DRILL_HOME/bin/drill-on-yarn.sh --site $DRILL_SITE resize -1
```

You can also resize your cluster using the Manage page of the Application Master web UI, by entering the number of desired nodes and clicking **Go**.

Stop the Cluster

You can stop the cluster from the command line or from the Manage page in the Application Master web UI.

To stop the cluster from the command line, issue the following command:

```
$DRILL_HOME/bin/drill-on-yarn.sh --site $DRILL_SITE stop
```

Migrate Drill to Run Under YARN

Explains how to migrate Drill to run under YARN instead of the Warden service.

When you migrate Drill to run under YARN, you must back up configurations, including files and storage plugins, shutdown the Drill cluster running under Warden, and uninstall Drill on all Drill nodes in the cluster. You may also want to determine which system settings have been changed from the Drill defaults.

NOTE: Drill-on-YARN is an advanced feature used to manage a production Drill cluster. Only skilled administrators, familiar with YARN, should configure Drill to run under YARN. If you are new to Drill, consider running Drill under the Warden service until you are familiar with Drill and Drill cluster management.

The sections below provide the tasks required to migrate Drill under YARN:

Tasks

Complete the following tasks when you want to migrate Drill to run under YARN:

Backup configurations and UDFs

Back up configuration files, storage plugin configurations, and UDFs (user-defined functions) or custom JAR files. Back up the configuration files located in `/opt/mapr/drill/drill-<version>/conf`, including `drill-override.conf` and `drill-env.sh`, to preserve your ZooKeeper configuration and any options or custom configurations specified in the files. Also back up `logback.xml` if you configured the file for the Lilith software.

- To back up configuration files, go to `/opt/mapr/drill/drill-<version>/conf`, and copy the files to a location outside of the Drill installation directory.

```
cp <file_name> drill-env.sh /
path/to/directory
```

- To back up custom JARs or UDFs, go to /opt/mapr/drill/drill-<version>/jars/3rdparty and copy the JARs or UDFs to a location outside of the Drill installation directory.
- To back up storage plugin configurations, complete the following steps:
 1. [Start the Web Console](#). The Drill node that you use to access the Web Console must be a node that is currently running the Drillbit process.
 2. Click **Storage**.
 3. Click **Update** next to a storage plugin.
 4. Copy the configuration to a text file, and save the file.
 5. Repeat steps 3 and 4 for each storage plugin configuration that you want to save.

Verify system option settings

Drill should save set system options when you migrate Drill. However, you may want to verify which system options were changed from the default settings beforehand. You can run the following query to see which system options were changed from the defaults:

```
select * from sys.options where
status = 'CHANGED';
```

Example:

```
select * from sys.options where
status = 'CHANGED';
+-----+-----+-----+-----+
|          name          |
| kind | type | status |
| num_val | string_val | bool_val |
| float_val |
+-----+-----+-----+-----+
| exec.errors.verbose
| BOOLEAN | SYSTEM | CHANGED |
| null | null | true |
| null |
| new_view_default_permissions
| STRING | SYSTEM | CHANGED |
| null | 777 | null |
| null |
| planner.enable_decimal_data_type
| BOOLEAN | SYSTEM | CHANGED |
| null | null | true |
| null |
| planner.enable_limit0_optimization
| BOOLEAN | SYSTEM | CHANGED |
| null | null | true |
| null |
+-----+-----+-----+-----+
4 rows selected (0.541 seconds)
```

Shutdown the Drill cluster

After you migrate, run the query again to verify that the system options are still set. If not, set the options.

Issue the following command to shutdown the existing Warden-managed Drill cluster:

```
maprccli node services -name
drill-bits -action stop -nodes <node
host names separated by a space>
```

NOTE: Do not shutdown nodes when queries are in progress.

Verify that Drillbits stopped

Run the following command to verify that the Drillbit service is no longer running on each node:

```
ps -ef | grep -i drill
```

No Drill processes should print to screen when you run this command.

You can also log in to the Control System at <https://<host name>:8443> to verify the status of the Drillbit service. You should not see Drillbit as a listed service.

Uninstall Drill

Uninstall Drill and then run `configure.sh -R` to refresh the configuration.

Issue the command appropriate for your system as root or using `sudo` to uninstall the `mapr-drill` package:

Operating System	Command
RedHat/CentOS	<code>yum remove mapr-drill</code>
Ubuntu	<code>apt-get remove mapr-drill</code>

NOTE: Verify that Drillbit processes stopped.

Additional Drill-on-YARN Configuration Options

You can include additional configuration options in the `$DRILL_SITE/drill-on-yarn.conf` file for specialized cases. For example, you can customize the Application Master web UI port or Application Master settings.

Refer to the `drill-on-yarn-example.conf` file in `$DRILL_HOME/conf` to see examples of the additional options. Do not use the example file.

The following list describes the changes that you can make for several of the Drill-on-YARN components:

Application Name

You can customize the application name that appears when starting or stopping the Drill cluster and in the Drill-on-YARN web UI. Change the value of the following option to a name you prefer:

```
app-name: "My Drill Cluster"
```

Application Master Web UI Port

If you run multiple Drill clusters in a YARN cluster, YARN may assign two Drill Application Master processes on the same node. To avoid port conflicts, change the HTTP port for one or both of the Drill

clusters. Change the value of the following option to a different port number:

```
drill.yarn:
  http: {
    port: 12345
  }
}
```

Application Master Settings

You can customize certain Application Master properties. All of the Application Master properties are prefixed with `drill.yarn.am`, for example `drill.yarn.am.heap`.

The following table lists the Application Master properties with their default settings:

Name	Description	Default
memory-mb	Memory, in MB, to allocate to the Application Master.	14336
vcores	Number of CPUS to allocate to the Application Master.	1
heap	Java heap for the Application Master.	450M

Drillbit

You can customize certain properties that control the Drillbit processes. All of the Drillbit properties are prefixed with `drill.yarn.drillbit`, for example `drill.yarn.drillbit.disks`.

 **NOTE:** You can specify Drill disk usage to YARN, however Drill uses all disks regardless of the setting.

The following table lists the Drillbit properties with their default settings:

Name	Description	Default
code-cache	Code cache that holds classes generated at runtime.	1G
memory-mb	Memory, in MB, to allocate to the Drillbit.	13000
vcores	Number of CPUS to allocate to the AM.	4

disks	Number of disk equivalents consumed by Drill (on versions of YARN that support disk resources.)	1
heap	Java heap memory.	4G
max-direct-memory	Direct (off-heap) memory for the Drillbit.	4G
log-gc	Enables Java garbage collector logging.	false
class-path	Additional class-path entries.	blank

Mapping of drill-env.sh to drill-on-yarn.conf Options

When you run Drill as a standalone application, you set startup options, such as Drillbit memory, in the \$DRILL_HOME/conf/drill-env.sh start up script. Under YARN, Drill still reads \$DRILL_SITE/drill-env.sh for configuration options, however Drill-on-YARN provides the \$DRILL_SITE/drill-on-yarn.conf file to configure options that were formerly set in drill-env.sh.

The following table maps the drill-env.sh environment variables to their equivalent configuration parameters in drill-on-yarn.conf:

drill-env.sh Environment Variable	drill-on-yarn.conf Configuration Parameter
DRILL_MAX_DIRECT_MEMORY *	drill.yarn.drillbit.max-direct-memory
DRILL_HEAP *	drill.yarn.drillbit.heap
DRILL_JAVA_OPTS	drill.yarn.drillbit.vm-args (Added to those in drill-env.sh.)
SERVER_GC_OPTS (to add GC logging)	Drill.yarn.drillbit.log-gc (To enable GC logging)
DRILL_HOME	Set automatically when files are localized (drill.yarn.drill-install. localize is true), else drill.yarn.drill-install. drill-home.
DRILL_CONF_DIR	Set automatically when files are localized, else uses the normal defaults.
DRILL_LOG_DIR	Set automatically to point to YARN's log directory unless disabled by setting drill.yarn.drillbit. disable-yarn-logs to false. If disabled, uses the normal Drill defaults.
DRILL_CLASSPATH_PREFIX *	Drill.yarn.drillbit. prefix-class-path
HADOOP_CLASSPATH *	drill.yarn.hadoop.class-path (or, better drill.yarn.drillbit. extn-class-path.)
HBASE_CLASSPATH *	Drill.yarn.hadoop. hbase-class-path (or, better drill.yarn.drillbit. extn-class-path.)
EXTN_CLASSPATH * (New in Drill 1.8.)	Drill.yarn.drillbit. extn-class-path
DRILL_CLASSPATH *	drill.yarn.drillbit.class-path

Multiple Drill Clusters within YARN

You can define multiple Drill clusters within a single YARN cluster. Each Drill cluster is a collection of Drillbits that work as an independent unit. For example, you might define one test Drill cluster that consists of a few machines on the same physical cluster that runs larger Drill clusters for development and marketing.

You must assign each Drill cluster a distinct ZooKeeper entry. Drill uses ZooKeeper to coordinate activities. Each Drill cluster also needs a distinct set of ports because YARN may launch Drillbits from different clusters on the same physical node.

The following steps summarize the process for defining multiple Drill clusters on a single YARN cluster:

1. Create a new site directory.
2. Configure Drill.
3. Configure Drill-on-YARN.
4. Start the cluster.

The following task provides instructions for each of the steps required to configure and run multiple Drill clusters under YARN:

Defining Multiple Drill Clusters within YARN

About this task

Complete the following steps to define multiple Drill clusters under YARN:

Procedure

1. Create a new "site" directory under \$DRILL_HOME, and create an environment variable for the directory.

```
mkdir $DRILL_HOME/<site_name>
export $<SITE_NAME>_SITE=$DRILL_HOME/<site_name>
```

2. Copy the following configuration files from the existing "site" directory into the new "site" directory:
 - drill-override.conf
 - drill-env.sh
 - drill-on-yarn.conf
 - distrib-env.sh

3. Modify the settings in the `drill.exec` section of `$DRILL_SITE/drill-override.conf` to configure the new Drill cluster to act independently of the other Drill cluster(s), or share settings, such as storage plugin configurations. For the new Drill cluster to act independently, give `zk.root` a distinct name from the existing clusters. In the more advanced scenario where the clusters share configurations, give `zk.root` the same name as the existing Drill clusters. When the clusters share the same root, they must have distinct cluster-id values. The user, bit, and http ports must have values distinct from all the other Drill clusters.

The following example shows a number 1 added to the first digit of the default port numbers, however you can choose any available ports.

```
drill.exec: {
  cluster-id: "drillbits",
  zk: {
    root: "<site_name>"
    connect: "zk-host:5181"
  }

  rpc {
    user.server.port: 41010
    bit.server.port: 41011
  }
  http.port: 9047
}
```

4. Modify the `drill-on-yarn.conf` configuration file for the new cluster. The new cluster must have a distinct name, a distinct upload directory in the filesystem, and a distinct port number.

The following settings in the `drill.yarn` section must have distinct values for the new cluster:

```
drill.yarn: {
  app-name: "Distinct Cluster Name"

  dfs: {
    app-dir: "/upload/directory"
  }

  http : {
    port: <distinct port number>
  }
}
```

5. Start the new cluster from the "site" directory that correlates with the new cluster.

```
$DRILL_HOME/bin/drill-on-yarn.sh --site $NEW_SITE start
```

Drill-on-YARN Command Line Tool

Run the Drill-on-YARN command line tool from the Drill-on-YARN client and use it to start, stop, resize, and check the status of the Drill cluster. When you launch Drill from the command line, the tool automatically archives and uploads the "site" directory, which YARN deploys (along with Drill) onto each node.

You can access the Drill-on-YARN command line tool in the following directory:

```
$DRILL_HOME/bin/drill-on-yarn.sh --site $DRILL_SITE command
```

where *command* is the operation you want to perform, such as `start`.

To avoid having to type the site argument for each command, set an environment variable:

```
export DRILL_CONF_DIR=$DRILL_SITE
```

The following example shows the start command after setting the environment variable:

```
$DRILL_HOME/bin/drill-on-yarn.sh start
```

Command Summary

The following table lists the commands and provides a brief summary for each:

Command	Description
start	Starts the Drill cluster. Prints the startup status followed by a summary of the application.
status	Retrieves basic information about the Drill cluster.
stop	Stops the Drill cluster.
resize <value> resize + <increase_node_count_by> resize - <decrease_node_count_by>	Adds or removes nodes in the Drill cluster while the cluster runs. You can specify the exact number of nodes you want to run, or you can use +/- to increase or decrease the current node count by a certain amount.
clean	Removes the cached Drill archive from the designated DFS directory.

Commands

The following sections provide detailed information and examples for each of the commands listed in the command summary:

start

The start command launches Drill and provides a startup status followed by a summary of the application.

The first line in the summary displays the cluster name from the configuration file to confirm which cluster is starting.

```
Launching Drill-on-YARN...
```

The next line shows the YARN application ID and tracks the job status from Accepted to Running.

```
Application ID:
application_1462842354064_0001
Application State: ACCEPTED
Starting.....
Application State: RUNNING
```

Once the job starts, you see the YARN job tracking URL with the Drill-on-YARN web UI URL.

```
Application Master URL: http://
<YARN_Job_Tracking_URL>:8048/
```

Once the application starts, the Drill-on-YARN writes an “appid” file into the Drill installation directory:

```
ls /opt/mapr/drill/drill-<version>
...
drillbits1.appid
```

The file name is the same as the Drill cluster ID. The file contains the ID of the Drill-on-YARN application. The other commands use this ID. You can run only one Drill application at a time. If you attempt to start a second from the same client machine on which you started the first, the client command complains that the appid file already exists. If you attempt to start the cluster from a different node, the second application detects a conflict and shuts down again.

Example

```
$DRILL_HOME/bin/drill-on-yarn.sh start

Launching Drill-on-YARN...
Application ID:
application_1462842354064_0001
Application State: ACCEPTED
Starting.....
Application State: RUNNING
Tracking
URL: http://10.250.50.31:8088/proxy/
application_1462842354064_0001/
Application Master URL: http://
10.250.50.31:8048/
```

status

The status command retrieves basic information about the Drill cluster and provides a status summary.

The first several lines of the status summary provide information about the state of YARN, which includes the application ID, the application state, and YARN's tracking URL for the application.

```
Application ID:
application_1462842354064_0001
Application State: RUNNING
Host: yosemite/10.250.50.31
Tracking URL:
```

Following the state of YARN information is the host on which the Drill application is running, the queue on which the application was placed, and the user who submitted the application. The start time tells you when YARN started the application.

```
http://10.250.50.31:8088/proxy/
application_1462842354064_0001/
Queue: default
User: drilluser
Start Time: 2016-05-09 16:56:40
```

The next few lines are specific to Drill, including the name of the application (which you configured in the drill-on-yarn.conf configuration file), the Drill

Application Master URL, the number of Drillbits you requested to run, and the number actually running.

```
Application Name: Drill-on-YARN
AM State: LIVE
Target Drillbit Count: 1
Live Drillbit Count: 1
```

Finally, the last line provides the URL for the Drill-on-YARN web UI.

```
For more information, visit: http://
10.250.50.31:8048/
```

Example

```
$DRILL_HOME/bin/drill-on-yarn.sh
status

Application ID:
application_1462842354064_0001
Application State: RUNNING
Host: yosemite/10.250.50.31
Tracking
URL: http://10.250.50.31:8088/proxy/
application_1462842354064_0001/
Queue: default
User: drilluser
Start Time: 2016-05-09 16:56:40
Application Name: Drill-on-YARN
AM State: LIVE
Target Drillbit Count: 1
Live Drillbit Count: 1
For more information, visit: http://
10.250.50.31:8048/
```

stop

The stop command stops the Drill cluster. This command is forceful and kills any in-flight queries. The output tracks the shutdown and displays the final YARN application status.

Example

```
$DRILL_HOME/bin/drill-on-yarn.sh stop

Stopping Application ID:
application_1462842354064_0001
Stopping...
Stopped.
Final status: SUCCEEDED
```

resize

The resize command changes the number of nodes in the cluster. You can use this command to add or remove nodes in the Drill cluster as it runs. You can specify the change either by giving the number of nodes you want to run, or by using the + or - to specify the change in node count.

Drill adds nodes only if additional nodes are available from YARN. If you request to stop more nodes than are running, Drill stops all of the running nodes.

Example

```
$DRILL_HOME/bin/drill-on-yarn.sh
resize 10
$DRILL_HOME/bin/drill-on-yarn.sh
resize +2
$DRILL_HOME/bin/drill-on-yarn.sh
resize -3
```

clean

The clean command removes the cached Drill archive from the designated DFS directory. If you run Drill-on-YARN for a temporary cluster, Drill leaves the Drill software archive in your designated DFS directory. Specifically, the first start uploads the Drill archive to DFS. Stop leaves the archive in DFS. Subsequent start commands reuse the cached archive if it is the same size as the version on the local disk. Clean removes the cached file, forcing Drill to upload a fresh copy if you again restart the Drill cluster.

Example

```
$DRILL_HOME/bin/drill-on-yarn.sh clean
```

Application Master Web UI

Drill, running as a YARN application, provides the Drill-on-YARN Application Master (AM) process to manage the Drill cluster. The Drill AM provides a web UI where you can monitor cluster status and perform simple operations, such as increasing or decreasing cluster size, or stopping the cluster.

When you launch Drill using the Drill-on-YARN command line tool, the tool signals YARN to launch the AM, which in turn launches the Drillbits in the cluster. When Drill starts, you can access the web UI using the URL provided at startup.

The following sections describe the information that the Application Master web UI provides:

Main

The main page provides the following information about the Drill cluster:

Drill Cluster Status

The Drill cluster status shows the state of the Drill cluster, which is one of the following:

- **LIVE:** This is the normal state and shows that the Drill cluster is running.
- **ENDING:** The cluster is in the process of shutting down

There is no “ENDED.” state. When the cluster shuts down, the web UI is no longer available.

Target Drillbit Count

The target Drillbit count is the number of Drillbits to run in the cluster. The actual number may be less if Drillbits have not yet started, or if YARN cannot allocate enough containers.

Live Drillbit Count

The live Drillbit count is the number of Drillbits that are ready for use. These have successfully started, have registered with ZooKeeper, and are ready for use. You can see the detail of all Drillbits (including those in the process of starting or stopping) using the Drillbits page. Each Drillbit must run on a separate node, so

	this is also the number of nodes in the cluster running Drill.
Total Drillbit Memory and Virtual Cores	The total number of YARN resources currently allocated to running Drillbits.
YARN Node Count, Memory, and Virtual Cores	Reports general information about YARN itself including the number of nodes, the total cluster memory, and total number of virtual cores.
Groups	Lists the cluster groups defined in the configuration file (only one is currently supported), along with the target and actual number of Drillbits in that group.

Configuration

The configuration page shows the complete set of configuration values used for the current run. The values come from the configurations you set and the Drill-provided defaults. Use this page to diagnose configuration-related issues. Names are shown in fully-expanded form. That is the name “drill.yarn.http.port” refers to the parameter defined, as follows, in your configuration file:

```
drill.yarn:
  http: {
    port: 8048
  }
}
```

Drillbits

The Drillbits page provides the following information about each of the Drillbits:

ID	A sequential number assigned to each new Drillbit. Numbers may not start with 1 if you have previously shut down some Drillbits.
Group	The cluster group that started the Drillbit. Cluster groups configured in drill-on-yarn.conf.
Host	The host name or IP address on which the Drillbit runs. If the Drillbit is in a normal operating state, this field is also a hyperlink to the Web UI for the Drillbit.
State	The operating state of the Drillbit. The normal state is “Running.” The Drillbit passes through a number of states as YARN allocates a container and launches a process, as the AM waits for the Drillbit to become registered in ZooKeeper, and so on. Similarly, the Drillbit passes through a different set of states during shutdown. Use this value to diagnose problems. If the Drillbit is in a live state, this field shows an “[X]” link that you can use to kill this particular Drillbit. Use this if the Drillbit has startup problems or seems unresponsive. During the shut-down process, the kill link disappears and is replaced with a “Cancelled” note.
ZK State	The ZooKeeper handshake state. Normal state is “START_ACK”, meaning that the Drillbit has registered with ZooKeeper. This state is useful when diagnosing problems.
Container ID	The YARN-assigned container ID for the Drillbit task. The ID is a link that takes you to the YARN Node Manager UI for the Drillbit task.

Memory and Virtual Cores (vcores)

The amount of resources actually allocated to the Drillbit by YARN.

Start Time

The date and time (in your local time-zone, displayed in ISO format) when the Drillbit launch started. This page also displays unmanaged Drillbits, if present. An unmanage Drillbit is one that is running, has registered with ZooKeeper, but was not started by the Application Master. Likely, the Drillbit was launched using the Drillbit.sh script directly. Use the host name to locate the machine running the Drillbit if you want to convert the Drillbit to run under YARN.

Manage

The Manage page provides options to resize or stop the Drill cluster. You can resize the cluster by adding or removing Drillbits or setting the cluster to a specific size.

Drill is a long-running application. Typically, Drill runs indefinitely, and you would only shut down the Drill cluster to perform an upgrade of the Drill software or to change configuration options. When you terminate the Drill cluster, any in-progress queries fail. Therefore, best practice is to perform the shutdown with users so that Drill is not processing any queries at the time of the shut-down.

When removing or shutting-down the cluster, you receive a confirmation page asking if you really do want to stop Drillbit processes. Click **Confirm** to continue.

History

The History page lists all failed, killed, and restarted Drillbits. You can detect failures and diagnose problems using the information on this page. Use the YARN container ID listed on this page to locate the log files for the Drillbit.

Enabling Application Master Web UI Security

By default, the Application Master Web UI is not secure and open to everyone. You can configure user authentication or implement a simple, predefined user name and password to secure the UI. Modify the drill-on-yarn.conf configuration file to enable Drill-on-YARN security.

The following sections describe how to enable security for the Application Master web UI.

User Authentication

You must enable [user authentication](#) in Drill if you want Drill-on-YARN to use this feature for security purposes. When user authentication is enabled, the user name and password must match that of the user that started the Drill-on-YARN application.

To secure the Application Master web UI by way of user authentication, modify drill-on-yarn.conf to include the following section with the auth-type set to drill:

```
drill.yarn.http: {
  auth-type: "drill"
}
```

Simple Security

Define a username and password in drill-on-yarn.conf and then restart the Drill-on-YARN Application Master to implement simple security for the Application Master web UI.

Modify the `drill-on-yarn.conf` configuration file to include the following section, replacing the user-name and password settings with yours, and then restart the Drill-on-YARN Application Master:

```
drill.yarn.http: {
  auth-type: "simple"
  user-name: "tsmith"
  password: "secret"
}
```

When you visit the web UI, a login page prompts you for the username and password that you configured. These are the only valid credentials.

Drill-on-YARN Limitations

Drill-on-YARN has the following limitations:

Hanging requests

Drill-on-YARN and YARN “hang” if YARN cannot fulfill a container request. YARN provides no information about why a request “hangs.”

/tmp directory

The default YARN settings cause Drillbits to become unmanaged within a short amount of time due to a /tmp directory issue. See the Exclude the YARN Container Directory from tmpwatch section in [Step 3: Configure YARN to Run Drill](#) for information on how to resolve the issue.

Container size

The default YARN settings do not allow a default Drill cluster to run due to the default YARN container size. See the Increase Maximum Container Size section in [Step 3: Configure YARN to Run Drill](#) for information on how to resolve the issue.

Drill disk usage

You can specify Drill disk usage to YARN, but Drill will use all disks regardless of the setting. There is no effective way to manage a Drill cluster that:

- resizes based on load.
- is rack-aware in its smaller state.

YARN chooses arbitrary nodes perhaps resulting in large network reads. (MD-1028, MD-1089)

Node Labels

Although the Apache YARN documentation states that you can associate node labels with YARN container requests, some people have noticed that the feature does not work in practice. While Drill-on-YARN configuration has settings to associate Drillbit container requests with node labels, doing so is not supported. To use node labels, associate node labels with YARN queues as described in the YARN configuration step in the [Migrate Drill to Run Under YARN](#) documentation.

Configuring Drill-on-Yarn on a Secure Cluster

Describes how to enable SASL for Drill and SQLLine to run Drill-on-YARN in a secure cluster.

About this task

Update the `drill_home/conf/distrib-env.sh` file with the required options. If you use `--site`, then use your site directory.

The following options are required for Drill and SQLLine to work with SASL security:

```
-Ddrill.customAuthFactories=org.apache.drill.exec.rpc.security.maprsasl.MapR
SaslFactory
-Dzookeeper.sasl.client=true
-Djava.security.auth.login.config=/opt/mapr/conf/mapr.login.conf
-Dzookeeper.saslprovider=com.mapr.security.maprsasl.MaprSaslProvider
-Dhadoop.login=hybrid_keytab
```

The following sections describe how to update the `drill_home/conf/distrib-env.sh` file with the options to ensure that Drill and SQLLine work with SASL for security.

Drill

To make Drill work with SASL, set `DRILL_JAVA_OPTS` as shown:

```
export DRILL_JAVA_OPTS="$
{DRILL_JAVA_OPTS} -Ddrill.customAuthFa
ctories=org.apache.drill.exec.rpc.secu
rity.maprsasl.MapRSaslFactory -Dzookee
per.sasl.client=true -Djava.security.a
uth.login.config=/opt/mapr/conf/
mapr.login.conf -Dzookeeper.saslprovid
er=com.mapr.security.maprsasl.MaprSasl
Provider -Dhadoop.login=hybrid_keytab"
```

SQLLine

To make SQLLine work with SASL, set `SQLLINE_JAVA_OPTS` as shown:

```
export SQLLINE_JAVA_OPTS="$
{SQLLINE_JAVA_OPTS} -Ddrill.customAuth
Factories=org.apache.drill.exec.rpc.se
curity.maprsasl.MapRSaslFactory -Dzook
eeper.sasl.client=true -Djava.security
.uth.login.config=/opt/mapr/conf/
mapr.login.conf -Dzookeeper.saslprovid
er=com.mapr.security.maprsasl.MaprSasl
Provider"
```

TIP: The following table describes each of the options:

Option	Description
drill.customAuthFactories	Required to make Drill and SQLLine work with SASL. It points to the authentication factories used for authentication. Provides a full classpath to the SASL implementation.
zookeeper.sasl.client	Required to make Drill and SQLLine work with Zookeeper in a SASL-enabled environment and ZooKeeper client authentication. It enables or disables SASL authentication in Drill and SQLLine for ZooKeeper connections.
zookeeper.saslprovider	Required to make Drill and SQLLine work with ZooKeeper in a SASL-enabled environment and ZooKeeper client authentication. It points to the authentication factories used for authentication in Drill and SQLLine for ZooKeeper connections. Provides a full classpath to the SASL implementation.
java.security.auth.login.config	Required to make Drill and SQLLine work with security. It points to a file with JAAS configurations. In the HPE environment it is /opt/mapr/conf/mapr.login.conf.
hadoop.login=hybrid_keytab	Required to make Drill work with SASL security. It points to the required JAAS configuration name.

Configuring Drill

Lists the Data Fabric specific configuration for Drill.

Drill is highly configurable. This document focuses on Data Fabric related configurations and refers to the open source [Apache Drill documentation](#) for generic information. Key things to configure are:

Drill memory

Determine the amount of heap and direct memory allocated to a Drillbit for query processing in a Drill cluster. See [Configuring Drill Memory](#) on page 4732.

Parquet block size

Change the Parquet block size to match the filesystem chunk size. See [Configuring the Parquet Block Size](#) on page 4734.

Resources for a shared Drillbit

Configure queues and parallelization for supporting multiple users sharing a Drillbit. Support separate Drillbits running on different nodes in the cluster. See [Configuring Resources for a Shared Drillbit](#).

Multitenancy

Configure a multitenant cluster to account for resources required for Drill. See [Configuring a Multitenant Cluster](#) on page 4739.

User Impersonation

Configure impersonation to allow a service to act on behalf of a client while performing the action requested by the client. See [User Impersonation](#) on page 4781.

User authentication and encryption

Configure user authentication when you want the identity of a user, before permitting the user access to a process running on a system. See [Default Security \(Tickets\)](#) on page 4793.

SSL/TLS for Encryption

Enable and configure SSL/TLS for encryption when you need to use Plain authentication. See [SSL/TLS for Encryption](#) on page 4813.

Drill impersonation with Hive authorization

Configure Drill impersonation to work with Hive impersonation to authorize access to metadata in the Hive metastore repository and data in the Hive warehouse. See [User Impersonation with Hive](#) on page 4787.

Volumes to use for spooling

Use the [drill.exec.spill.directories](#) option to set MapReduce volumes or local volumes for spooling to improve performance and stripe data across as many disks as possible.

Persistent configuration storage

See [Persistent Configuration Storage](#) and [Configuring the ZooKeeper PStore Location](#) on page 4740.

Access rights

Configure access rights if you have 777 file-level permissions to a table, and a query returns no results. See [Configuring Access Rights](#).

Drill typically runs along side other workloads, including the following:

- MapReduce
- Yarn
- Hive and Pig
- Spark

You need to plan and configure these resources for use with Drill and other workloads:

- Memory
- CPU
- Disk

Configuring Access Rights

If the security in your organization limits access to HPE Data Fabric Database tables, you might experience a problem querying the tables. If you have 777 file-level permissions to a table, yet a query returns no results, you might need to add your user name to the maprccli [ACL](#).

Adding a Drill Node to a Cluster**About this task**

To add a new node to a cluster that provides the Drillbit service, add the node to the cluster first, and then install Drill on the new node. If you install Drill first, and then add the node to the cluster, the cluster cannot detect ZooKeeper information and the cluster is misnamed. These problems require some work to resolve. You need to edit the drill-override.conf file in the mapr/drill directory and modify the name of the cluster. Avoid this extra work, and install Drill only after adding the node to the cluster by performing steps in the following order:

Procedure

1. Follow instructions for [adding a node to a cluster](#).
2. Reconfigure the cluster as described in the same instructions.
3. Verify that the new node is up and running.
4. Stop Warden, as shown:

```
$ service mapr-warden stop
```

5. Stop ZooKeeper service, as shown:

```
$ service mapr-zookeeper stop
```

6. [Configure the repository](#) to add the ecosystem repository.
7. [Install Drill](#) on the new node.
8. Reconfigure the node.

```
$ /opt/mapr/server/configure.sh -R
```

9. Start ZooKeeper if the node is a ZooKeeper node.
10. Start warden to make configuration changes effective.

Results

Verify that the Drillbit service is running on the node. It might take a minute or so for the Drillbit to start after starting warden.

Configuring Drill Memory

A system administrator can modify the amount of system memory that Warden allocates to the Drill service on each node in the `warden.drill-bits.conf` file. Drill users, with file permissions, can modify the amount of heap and direct memory allocated to the Drill service on each node in the `drill-env.sh` file.

NOTE: The cumulative memory allocation in `drill-env.sh` cannot exceed the memory allocation in `warden.drill-bits.conf`.

After modifying `drill-env.sh`, restart Drill:

```
$ maprcli node services -name drill-bits -action restart -nodes
<space-separated-list-of-drill-hostnames>
```

After modifying `warden.drill-bits.conf`, run the configuration script, [configure.sh](#), to update the node configuration and then restart Drill:

```
/opt/mapr/server/configure.sh -R
$ maprcli node services -name drill-bits -action restart -nodes
<space-separated-list-of-drill-hostnames>
```

The following sections describe the `warden.drill-bits.conf` and `drill-env.sh` files in detail.

Drill Memory Allocation in a Warden-Managed Cluster

If you install and run Drill under the Warden service, Warden manages the amount of system memory that Drill can use. By default, Warden allocates 20% of the system memory on a node to the Drill service. For example, if a node has 50GB of memory, Warden allocates 10GB (20% of 50GB) to the Drill service.

A system administrator can define the amount of memory that Warden allocates to Drill by changing the value of the `DRILLBIT_MAX_PROC_MEM` variable in `/opt/mapr/drill/drill-<version>/conf/warden.drill-bits.conf`.

When starting, Drill verifies that the amount of memory configured in `drill-env.sh` does not exceed the limit set by the `service.env=DRILLBIT_MAX_PROC_MEM` variable in `warden.drill-bits.conf`. If the settings in `drill-env.sh` exceed the setting in Warden, the system prints a message stating the issue; Warden does not start the Drill service on the node.

The `warden.drill-bits.conf` file contains the following settings:

NOTE: Drill automatically configures the `service.heapsize` parameters. Do not modify them.

```
#Default Drill Mem Distrib: 20% of System memory
service.env=DRILLBIT_MAX_PROC_MEM=20%
//Specifies the maximum amount of memory that Warden will allocate to the
Drill service on the node. You can set this value as a percentage of system
memory or as an absolute value in GB. Memory configured in drill-env.sh
cannot exceed this memory setting.

service.heapsize.min=5120
//Minimum heap size. Do not change this value. The value is auto-populated
and represents the minimum memory that the Drillbit process will take.

service.heapsize.max=13312
//Maximum heap size. Do not change this value. The value is auto-populated
and represents the maximum memory that the Drillbit process will take.

#Warden will allocate 20% of memory for Drill
service.heapsize.percent=20
//Do not change this value. Total heap size available based on the value
set for the DRILLBIT_MAX_PROC_MEM variable. If the variable is defined in
absolute values, it is represented as a percent of the system memory.
```

Drill Memory Allocation in drill-env.sh

You can configure the amount of heap and direct memory allocated to Drill on each node in the `/opt/mapr/conf/conf.d/drill-env.sh` file. If you do not manually configure the heap and direct memory, Drill calculates these values based on the amount of system memory that Warden allocates to Drill and auto-populates the settings for the variables.

The cumulative amount of memory allocated to Drill in `drill-env.sh` cannot exceed the amount of memory that Warden allocates to Drill, which is set by the `DRILLBIT_MAX_PROC_MEM` variable in `warden.drill-bits.conf`.

NOTE: The values in `drill-env.sh`, such as 13G, are examples and do not indicate the default memory limits for Drill. By default, Warden allocates 20% of the system memory on a node to Drill.

The `drill-env.sh` file contains the following memory variables that you can uncomment and modify:

```
#export DRILLBIT_MAX_PROC_MEM=${DRILLBIT_MAX_PROC_MEM:-"13G"}
//Specifies the maximum amount of system memory that the Drill service
can use on a node. Must be equal to or less than the value set for
DRILLBIT_MAX_PROC_MEM in warden.drill-bits.conf. You can set this value as
a percentage of system memory or as an absolute value in GB. If you define
this variable, without defining the heap and direct memory variables, Drill
automatically calculates the heap and direct memory values.

#export DRILL_HEAP=${DRILL_HEAP:-"4G"}
//Maximum theoretical heap limit for the JVM per node.

#export DRILL_MAX_DIRECT_MEMORY=${DRILL_MAX_DIRECT_MEMORY:-"8G"}
//Java direct memory limit per node.

#export DRILLBIT_CODE_CACHE_SIZE=${DRILLBIT_CODE_CACHE_SIZE:-"1G"}
//The memory limit for the compiled code generated by the JVM JIT compiler.
Do not modify. The value for this parameter is auto-computed based on the
heap size and cannot exceed 1GB.
```

NOTE: If performance is an issue, add `-Dbounds=false`, as shown:

```
export DRILL_JAVA_OPTS="$DRILL_JAVA_OPTS -Dbounds=false"
```

Configuring the Parquet Block Size

The default value for the `store.parquet.block-size` parameter is 268435456 (256 MB), the same size as file system chunk sizes. In previous versions of Drill, the default value was 536870912 (512 MB).

If you change the file system chunk size, change the Parquet block size to match using the [ALTER SYSTEM](#) or [SET](#) commands, as shown:

```
ALTER SYSTEM SET `store.parquet.block-size` = <value>;
[ALTER SESSION] SET `store.parquet.block-size` = <value>
```

Alternatively, you can override the default setting in the `<DRILL_HOME>/conf/drill-override.conf` file, as shown:

```
drill.exec: {
  ...
  options.store.parquet.block-size = 268435456
}
```

For information about setting the file system chunk size, see [Setting Chunk Size](#).

Configuring Multiple Drill Clusters and Designating One Cluster as an OJAI Distributed Query Service

As of Core 6.0 and Drill 1.11, you can run operational queries through the OJAI Distributed Query Service, as well as analytical queries through Drill. If you want to run operational and analytical workloads in your cluster, you must configure multiple Drill clusters within the cluster and then configure a Drill cluster as the OJAI Distributed Query Service. Restricting each workload to its own cluster improves query performance.

NOTE: Installing Drill and the OJAI Distributed Query Service together through the Installer is not currently supported. Only one of these services running in the cluster is supported unless you manually install and configure multiple Drill clusters, as instructed here.

Data Distribution

If you install both Drill and the OJAI Distributed Query Service through the Installer, both workloads get processed across the entire cluster. When both services run together in the cluster, the system replicates data across the entire cluster, causing remote reads and impairing performance, which can lead to missed SLAs and memory issues.

Memory Allocation

The amount of memory allocated to Drill and the OJAI Distributed Query Service differ. By default, when you install Drill, 13 GB of memory is allocated to the Drillbit service running on a node:

- 8 GB direct
- 4 GB heap
- 1 GB core cache

The OJAI Distributed Query Service less memory than Drill. By default, the OJAI Distributed Query Service is allocated ~ 5 GB of memory:

- 1 GB direct
- 3 GB heap

- 512 MB core cache

If you use the Installer and select both Drill and the OJAI Distributed Query Service, memory is configured for Drill. If you only run operational queries, which do not use as much memory as analytical queries, you unnecessarily lose an additional 8 GB of memory.

How to Run Drill and the OJAI Distributed Query Service Together in a Cluster

You can manually install Drill on several nodes and divide the nodes into multiple topologies (Drill clusters). For each of the topologies, create and mount a volume. Then, create directories within each volume to store your data. Configure these directories as workspaces in the Drill dsf storage plugin. Finally, configure a Drill cluster to run as an OJAI Distributed Query Service.

The following topics provide instructions for each of the required steps:

Step 1: Plan the Clusters

Decide which nodes in the cluster you want to run Drill and which nodes you want to run the OJAI Distributed Query Service.

The nodes you select to run Drill can form one or more Drill clusters, while the nodes you select to run the OJAI Distributed Query Service can form another Drill cluster. You can configure multiple Drill clusters.

For example, if you have a ten node cluster, you can configure one Drill cluster to run analytical queries and one OJAI Distributed Query Service cluster to run OJAI operational queries, as shown:

Track the nodes that you want to group into a cluster, as this information is needed to configure node topology and volumes. Also note the memory requirements of each service. Only non-overlapping Drill clusters are supported. You cannot install more than one Drillbit on a server node.

Step 2: Manually Install Drill on All Nodes

Manually install Drill on all nodes, including the nodes designated to run the OJAI Distributed Query Service.

For Drill installation instructions, see [Installing Drill](#). You can install Drill to run under Warden or YARN, as described in the following following topics:

- [Install Drill to Run Under Warden](#)
- [Install Drill to Run Under YARN](#)

Step 3: Define Node Topologies

Node topologies restrict data to a designated set of nodes.

When you define a topology, data is only replicated on the nodes within the topology. Node topologies improve query performance because data is localized to the nodes specified in the topology instead of being distributed across the entire cluster.

You can create node topologies for the Drill clusters in the UI or from the CLI. See [Changing Topology for One or More Nodes](#) for instructions.

When you create a topology, you define the nodes that form a Drill cluster, as shown in the following image:

The image shows two node topologies, T1 and T2. T1 is the Drill cluster to be configured as the OJAI Distributed Query Service. T2 is the Drill cluster that will remain a Drill service cluster.

Step 4: Create Volumes

Volumes organize data and manage cluster performance. Create and mount a volume to each of the topologies (Drill clusters) you created.

For example, you can create a volume named "operational" and mount it to the T1 topology and then create a volume named "analytical" and mount it to the T2 topology.

See [Administering Volumes](#) for volume information and [Creating a Volume](#) on page 1437 for instructions.

Once you create the volumes, you have a place where you can create directories and store data. For example, you can create and store operational data in the /operational/data/here directory and analytical data in the /analytical/data/here directory.

Use these directories to configure the workspaces in the Drill dfs storage plugin configuration.

Step 5: Configure Multiple Drill Clusters

Update the /opt/mapr/drill/drill-<version>/conf/drill-override.conf file on each Drill node that is part of a cluster with the cluster ID and a ZooKeeper entry to define the Drill cluster. Each Drill cluster should have a unique cluster ID and ZooKeeper entry to separate the clusters.

NOTE: Each Drill node in a cluster must have the same configuration.

The Drillbit process reads the configuration file and communicates with ZooKeeper to see if the cluster it belongs to exists. If the cluster exists, ZooKeeper says to join the cluster. If the cluster does not exist, the Drillbit initiates a new Drill cluster based on the cluster ID.

The following table provides an example of unique cluster IDs and ZooKeeper entries based on the topologies in the image shown in step 3, Define Node Topologies:

Cluster	Nodes	Cluster ID	ZooKeeper Entry
QS1	10.10.100.1 10.10.100.2	cluster-id: "drillbits"	zk.root: "drill"

D1	10.10.100.3 10.10.100.4 10.10.100.5 10.10.100.6 10.10.100.7 10.10.100.8 10.10.100.9 10.10.100.10	cluster-id: "drillbits2"	zk.root: "drill2"
----	---	--------------------------	-------------------

For QS1, drill-override.conf must include the following configuration:

```
drill.exec: {
  zk.root: "drill",
  cluster-id: "drillbits",
  zk.connect: "<zk-node-ip-address>:5181",
}
```

For D1, drill-override.conf must include the following configuration:

```
drill.exec: {
  zk.root: "drill2",
  cluster-id: "drillbits2",
  zk.connect: "<zk-node-ip-address>:5181",
}
```

NOTE: If you installed Drill to run under YARN, follow the steps in [Defining Multiple Drill Clusters Under YARN](#) for each Drill node. Drill running under YARN requires some additional steps, such as changing ZooKeeper ports.

Step 6: Configure Workspaces

You must configure a workspace on one Drill node in each Drill cluster that points to the volume directory where data is stored. When you create a workspace, you must include the volume mount point.

For example, if you created a volume with the mount point `/operational` for the OJAI Distributed Query Service cluster and stored your data in `/data/here/` within that volume, you would configure the workspace, as shown:

```
{
  "type": "file",
  "enabled": true,
  "connection": "file:/// ",
  "workspaces": {
    "root": {
      "location": "/",
      "writable": false,
      "defaultInputFormat": null
    },
    "tmp": {
      "location": "/tmp",
      "writable": true,
      "defaultInputFormat": null
    },
    "operational": {
      "location": "/operational/data/here",
      "writable": true,
      "defaultInputFormat": null
    }
  }
}
```

```
    }
}
```

Likewise, if you also created a volume with a mount point `/analytical` for the other Drill cluster that runs analytical queries and stored your data in `/data/here/` within that volume, you would configure the workspace, as shown:

```
{
  "type": "file",
  "enabled": true,
  "connection": "file:///",
  "workspaces": {
    "root": {
      "location": "/",
      "writable": false,
      "defaultInputFormat": null
    },
    "tmp": {
      "location": "/tmp",
      "writable": true,
      "defaultInputFormat": null
    },
    "analytical": {
      "location": "/analytical/data/here",
      "writable": true,
      "defaultInputFormat": null
    }
  }
}
```

You can define a workspace in the Drill dfs storage plugin configuration on the Storage page in the Drill Web UI at `https://<drill-node-ip-address>:8047`. You only need to configure the workspace on one Drill node in each Drill cluster.

See [Plugin Configuration Basics](#) and [Workspaces](#) for more information.

Step 7: Register a Drill Cluster as an OJAI Distributed Query Service

You can select any of the configured Drill clusters to act as the OJAI Distributed Query Service provider for operational queries, by running the `queryservice setconfig` command.

When you register the Drill cluster as the OJAI Distributed Query Service, adjust the memory setting on each node. The default Drill memory setting of 13 GB is unnecessarily high for the OJAI Distributed Query Service, which only requires ~ 5 GB. You must restart the Drillbits after you update the memory settings.

Registering a Drill Cluster as the OJAI Distributed Query Service

To register a Drill Cluster as an OJAI Distributed Query Service, run the following command:

```
maprcli cluster queryservice setconfig -enabled true -clusterid
<name_of_cluster> -storageplugin dfs -znode <zk_setting>
```

For example, `drillbits2` and `drill2` are the cluster ID and ZooKeeper settings used in examples in previous steps. For these configurations, the command is:

```
maprcli cluster queryservice setconfig -enabled true -clusterid
drillbits2 -storageplugin dfs -znode drill2
```

See [queryservice setconfig](#) for more information about the command.

Configuring Memory for the OJAI Distributed Query Service

Modify the memory settings on each node in the OJAI Distributed Query Service cluster and then restart Drill. See [Configuring Drill Memory](#) on page 4732 for instructions.

Configuring a Multitenant Cluster

Drill operations are memory and CPU-intensive. Currently, Drill resources are managed outside of any cluster management service, such as the Warden service. In a multi-tenant or any other type of cluster, YARN-enabled or not, you configure memory and memory usage limits for Drill by modifying `drill-env.sh` as described in the section, "[Configuring Drill Memory](#)" in Apache Drill documentation.

Configure a multitenant cluster to account for resources required for Drill. For example, on a cluster, ensure warden accounts for resources required for Drill. Configuring `drill-env.sh` allocates resources for Drill to use during query execution, while configuring the following properties in `warden-drill-bits.conf` prevents warden from committing the resources to other processes.

```
service.heapsize.min=<some value in MB>
service.heapsize.max=<some value in MB>
service.heapsize.percent=<a whole number>
```

Set the `service.heapsize` properties in `warden.drill-bits.conf` regardless of whether you changed defaults in `drill-env.sh` or not.

"[Configuring Drill in a YARN-enabled Cluster](#)" shows an example of setting the `service.heapsize` properties. The `service.heapsize.percent` is the percentage of memory for the service bounded by minimum and maximum values. Typically, users change `service.heapsize.percent` because using a percentage setting increases or decreases resources according to different node configurations. For more information about the `service.heapsize` properties, see the section, "[warden.<servicename>.conf](#)."

You need to statically partition the cluster to designate which partition handles which workload. To configure resources for Drill in a cluster, modify one or more of the files created by the installation process in `/opt/mapr/conf/conf.d`:

```
warden.drill-bits.conf
warden.nodemanager.conf
warden.resourcemanager.conf
```

Configure Drill memory by modifying `warden.drill-bits.conf` in YARN and non-YARN clusters. Configure other resources by modifying `warden.nodemanager.conf` and `warden.resourcemanager.conf` in a YARN-enabled cluster.

Configuring Drill in a YARN-enabled Cluster

To add Drill to a YARN-enabled cluster, change memory resources to suit your application. For example, you have 120G of available memory that you allocate to following workloads in a Yarn-enabled cluster:

File system = 20G Yarn = 20G OS = 8G

If Yarn does most of the work, give Drill 20G, for example, and give Yarn 60G. If you expect a heavy query load, give Drill 60G and Yarn 20G.

YARN consists of two main services:

- **ResourceManager:** There is at least one instance in a cluster, more if you configure high availability.
- **NodeManager:** There is one instance per node.

The `warden.resourcemanager.conf` and `warden.nodemanager.conf` files set ResourceManager and NodeManager memory to the following defaults:

```
service.heapsize.min=64
service.heapsize.max=325
service.heapsize.percent=2
```

Change these settings for NodeManager and ResourceManager to reconfigure the total memory required for YARN services to run. If you want to place an upper limit on memory, set the `YARN_NODEMANAGER_HEAPSIZE` or `YARN_RESOURCEMANAGER_HEAPSIZE` environment variable in

```
/opt/mapr/hadoop/hadoop-2.5.1/etc/hadoop/yarn-env.sh
```

You do not set the `-Xmx` option, allowing memory to grow as needed.

MapReduce Version 2 and other Resources

You configure memory for each service by setting three values in `warden.conf`.

```
service.command.<servicename>.heapsize.percent
service.command.<servicename>.heapsize.max
service.command.<servicename>.heapsize.min
```

[Configure memory](#) for other services in the same manner. For more information about managing memory in a cluster, see the following sections:

- [Memory Allocation for Nodes](#)
- [Cluster Resource Allocation](#)

How to Manage Drill CPU Resources

Currently, you do not manage CPU resources within Drill. Use Linux [cgroups](#) to manage the CPU resources.

Configuring the ZooKeeper PStore Location

By default, the ZooKeeper PStore offloads query profile data to `maprfs:///apps/drill/profiles`. You can override the default location in the `drill-override.conf` file.

When query profile data is stored on a distributed system, like the Data Fabric filesystem, you can see a [global query list](#) (view of query profiles coordinated by all Drill nodes in one Web UI).

To change the [ZooKeeper PStore](#) location, update the `drill.exec` block in `/opt/mapr/drill/drill-<version>/conf/drill-override.conf` with the following configuration, as shown:

```
drill.exec: {
  cluster-id: "my_cluster_com-drillbits",
  zk.connect: "<zkhostname>:5181",
  sys.store.provider.zk.blobroot: "maprfs:///new/storage/location/"
}
```

NOTE: By default, the filesystem replicates the data three times. If you are concerned about storage consumption, you can create a new volume specifically for query profile data, and set the replication value to 1 for that volume. After you create the volume, update `sys.store.provider.zk.blobroot` to point to the volume. See [Creating a Volume](#) on page 1437 for additional information.

After you modify `drill-override.conf`, restart Drill:

```
maprccli node services -name drill-bits -action restart -nodes
<drill-hostnames-separated-by-a-space>
```

Configuring HBase Persistent Storage Tables

Describes how to configure Drill to persist query profile data to a table that is unaffected by the TTL duration.

You can configure HBase persistent storage tables that do not have a TTL in the following versions of Drill:

- Drill 1.16.0.500 (EEP-8.1.1)
- Drill 1.20.2 (EEP 9.0.0 on Core 7.1.0) and later

By default, the Drill HBase persistent store persists the following information in one HBase table:

- Query profile data
- State information for storage plugins
- State information for ALTER SYSTEM settings

Data persists in the HBase table for the duration of the configured TTL, after which the data is automatically removed to free up space.

You can configure the system to persist query profiles to another table that does or does not have a TTL configured. Query profiles persist in the table until the query profiles are deleted or the TTL expires.

The following section describes how to configure HBase persistent storage.

Persistent Storage Configurations

Configure HBase persistent storage through the `sys.store.provider.hbase.table` option in the `/opt/mapr/drill/drill-<version>/conf/drill-override.conf` or `/opt/mapr/drill/drill-<version>/conf/drill-distrib.conf` file.

The following sections provide HBase persistent storage configuration options.

IMPORTANT: For insecure Data Fabric clusters (maprsasl disabled), exclude the `hbase.security.authentication` property from the configuration.

Default Persistent Storage Configuration

The following example configuration shows the default persistent storage configuration:

```
drill.exec.sys.store.provider: {
  class:
  "org.apache.drill.exec.store.hbase.config.HBasePStoreProvider",
  hbase: {
    table: "drill_store",
    config: {
      "hbase.zookeeper.quorum":
      "node1.com,node2.com,node3.com",

      "hbase.zookeeper.property.clientPort":
      "5181",

      "hbase.security.authentication":
      "maprsasl"
    }
  }
}
```

```
}
}
```

With this configuration, the HBase table `drill_store` stores query profile data and state information for storage plugins and ALTER SYSTEM settings until they expire based on the set TTL.

Query Profile Persistent Storage Configuration

If you want to store query profile data in a separate table, add the `drill.exec.sys.store.provider.hbase.blob.table` property to the persistent storage configuration, as shown in the following example:

```
drill.exec.sys.store.provider: {
  class:
  "org.apache.drill.exec.store.hbase.config.HBasePStoreProvider",
  hbase: {
    blob.table: "drill_blob_store",
    table: "drill_store",
    config: {
      "hbase.zookeeper.quorum":
      "node1.com,node2.com,node3.com",

      "hbase.zookeeper.property.clientPort":
      "5181",

      "hbase.security.authentication":
      "maprsasl"
    }
  }
}
```

With this configuration, the Hbase table `drill_blob_store` stores query profiles only. The HBase table `drill_store` stores storage plugins and ALTER SYSTEM settings.

IMPORTANT: Drill cannot access query profile data stored in `hbase.table` (`drill_store`) after you configure `blob.table` (`drill_blob_store`).

Configuring cgroups to Control CPU Usage

Starting in Drill 1.13, you can configure a Linux cgroup (control group) to enforce CPU limits on the Drillbit service running on a node. Linux cgroups enable you to limit system resources to defined user groups or processes. You can use the `cgconfig` service to configure a Drill cgroup to control CPU usage and then set the CPU limits for the Drill cgroup on each Drill node in the `/etc/cgconfig.conf` file.

NOTE: Cgroups V2 is recommended.

Before You Begin

Each Drill node must have the `libcgroup` package installed to configure CPU limits for a Drill cgroup. The `libcgroup` package installs the `cgconfig` service required to configure and manage the Drill cgroup.

Install the `libcgroup` package using the `yum install` command, as shown:

```
yum install libcgroup
```

Enable Drill to Directly Manage CPU Resources

Starting in Drill 1.14, Drill can directly manage CPU resources through the start-up script, `drill-env.sh`, which means that you no longer have to manually add the PID (Drill process ID) to the `cgroup.procs` file each time a Drillbit restarts. This step occurs automatically upon restart. The start-up script checks for the specified cgroup, such as `drillcpu`, and then applies the cgroup to the launched Drillbit JVM. The Drillbit CPU resource usage is then managed under the cgroup, `drillcpu`.

For Drill to directly manage CPU resources, you must enable (uncomment) the following variables in the `drill-env.sh` script:

Variable	Description
<code>export DRILLBIT_CGROUP=\$ {DRILLBIT_CGROUP:-"drillcpu"}</code>	Sets the cgroup to which the Drillbit belongs when running as a daemon using <code>drillbit.sh start</code> . Drill uses the cgroup for CPU enforcement only.
<code>export SYS_CGROUP_DIR=\$ {SYS_CGROUP_DIR:-"/sys/fs/cgroup"}</code>	Drill assumes the default cgroup mount location set by systemd (the system and service manager for Linux operating systems). If your cgroup mount location is in a different location, change the setting to match your location.
<code>export DRILL_PID_DIR=\$ {DRILL_PID_DIR:-\$DRILL_HOME}</code>	The location of the Drillbit PID file when Drill is running as a daemon using <code>drillbit.sh start</code> . By default, this location is set to <code>\$DRILL_HOME</code> .

IMPORTANT: If you have Drill 1.13 running on the node, or you have Drill 1.14 running on the node and you do not want to enable Drill to directly manage the CPU resources through `drill-env.sh`, you must manually update the `/cgroup/cpu/drillcpu/cgroup.procs` file with the PID (Drill process ID), as shown, each time a Drillbit restarts to enforce the CPU limit for the Drillbit service:

```
echo 25809 > /cgroup/cpu/drillcpu/cgroup.procs
```

Set the CPU Limit for the Drillbit Service

You can set the CPU limit as a soft or hard limit, or both. You set the limits with parameters in the `/etc/cgconfig.conf` file. The hard limit takes precedence over the soft limit. When Drill hits the hard limit, in-progress queries may not complete. Review the following sections that describe the soft and hard limit parameters and then configure CPU limits.

Soft Limit Parameter

You set the soft limit with the `cpu.shares` parameter. This parameter takes an integer value, which specifies a relative share of CPU time available to the tasks in a cgroup. For example, if there are two tasks and `cpu.shares` is set to 100, each task receives half of the CPU time. The value must be 2 or greater. When you set a soft limit, Drill can exceed the CPU allocated if extra CPU is available for use on the system. Drill can continue to use CPU until there is contention with other processes over the CPU or Drill hits the hard limit.

Hard Limit Parameters

You set the hard limit on the amount of CPU time that the Drill process can use through the `cpu.cfs_period_us` and `cpu.cfs_quota_us` parameters.

- `cpu.cfs_period_us`

Specifies a period in microseconds (represented by `us` for μs) to indicate how often a cgroup's access to CPU resources should be reallocated. For example, if you want tasks in a cgroup to have access to a single CPU for 0.2 seconds in a 1 second window, set `cpu.cfs_quota_us` to 200000 and `cpu.cfs_period_us` to 1000000. The upper limit of the `cpu.cfs_quota_us` parameter is 1 second and the lower limit is 1000 microseconds.

- `cpu.cfs_quota_us`

Specifies the total amount of runtime in microseconds (represented by `us` for μs), for which all tasks in the Drill cgroup can run during one period (as defined by `cpu.cfs_period_us`). When tasks in the Drill cgroup use up all the time specified by the quota, the tasks are throttled for the remainder of the time specified by the period and they cannot run until the next period. For example, if tasks in the Drill cgroup can access a single CPU for 0.2 seconds out of every 1 second, set `cpu.cfs_quota_us` to 200000 and `cpu.cfs_period_us` to 1000000. Setting the `cpu.cfs_quota_us` value to -1 indicates that the group does not have any restrictions on CPU. This is the default value for every cgroup, except for the root cgroup.

Configuring CPU Limits

Complete the following steps to set a hard and/or soft CPU limit for the Drill process running on the node:

1. Start the `cgconfig` service:

```
service cgconfig start
```

2. Add a cgroup for Drill in the `/etc/cgconfig.conf` file:

```
group drillcpu {
    cpu {
        cpu.shares = 320;
        cpu.cfs_quota_us = 400000;
        cpu.cfs_period_us = 100000;
    }
}
```

In the configuration example above, the `cpu.shares` parameter sets the soft limit. The other two parameters, `cpu.cfs_quota_us` and `cpu.cfs_period_us`, set the hard limit. If you prefer to set only one type of limit, remove the parameters that do not apply. When setting a soft limit, allocate a specific number of CPU shares to the Drill cgroup in the configuration. Calculate the CPU shares as:

```
1024 (CPU allocated to Drill/Total available CPU)
```

In the example, CPU shares is calculated as:

```
1024 (10/32) = 320
```

When setting a hard limit, add limits to the `cpu.cfs_quota_us` and `cpu.cfs_period_us` parameters. In the example, the Drill process can fully utilize 4 CPU.

TIP:

The hard limit parameter settings persist after each cgroup service restart. Alternatively, you can set the parameters at the session level using the following commands:

```
echo 400000 > /cgroup/cpu/drillcpu/cpu.cfs_quota_us
echo 100000 > /cgroup/cpu/drillcpu/cpu.cfs_period_us
```

3. (Optional) If you want the `cgconfig` service to automatically restart upon system reboots, run the following command:

```
chkconfig cgconfig on
```

https://access.redhat.com/documentation/en-us/red_hat_enterprise_linux/6/html/resource_management_guide/sec-cpu

Drill Properties

Describes how to use Drill properties and options.

Boot Options

Drill has a flexible system of configuration with a property-source hierarchy. This hierarchy allows Drill to seek further for a property even if a prioritized property source does not have the property.

The following table shows the order of loading Drill properties in a Drillbit. These properties are also known as start-up options or boot options.

Drill searches for a property from top to bottom:

Options source	User Modifiable?	Description
drill-override.conf	Yes	HOCON -formatted configuration file stored in the Drill configuration directory. This file is intended to be populated with user properties.
Java System Properties	Yes	Java System Properties use java options to set a boot option: -Doption=value. Java options can be added to the drill-env.sh config to the DRILLBIT_JAVA_OPTS variable. For example: export DRILLBIT_JAVA_OPTS="\$DRILLBIT_JAVA_OPTS -Dproperty=value"
drill-distrib.conf	No*	HOCON -formatted configuration file stored in the Drill configuration directory. This file contains distribution-specific options and is populated automatically based on the cluster configuration. The file contents can change after you run the configure.sh on page 3186 utility.
drill-module.conf	No*	HOCON -formatted configuration file stored in Drill jars, one per single jar. These configuration files have default values for various Drill modules. It can be a storage plugin jar, UDF jar, Drill execution module, or other module. Developers set the default values. This configuration file can change from release to release.
drill-default.conf	No*	HOCON -formatted configuration file stored in drill-common jar. Developers set the default values. This configuration file can change from release to release.

*Users should not modify the options source.

Drill has a wide list of options. To understand the possible options that can be set, check the drill-override-example.conf file in the <Drill home>/conf directory.

To see all set Drill boot options, you can query the boot [system table](#). For example:

```
apache drill> select * from sys.boot;
```

```
+-----+-----+-----+-----+-----+-----+
|          name          | kind  | | |
| accessibleScopes | optionScope | status | num_val |
| string_val      | bool_val | float_val |
+-----+-----+-----+-----+-----+-----+
| awt.toolkit      |         |         |         | STRING |

| null | null |
| drill.exec.allow_loopback_address_binding | BOOLEAN |
BOOT | BOOT | BOOT | null |
null | false | null |
...

```

Configuration Options

Drill configuration options are boot options that have the `drill.exec.options.*` prefix. The main difference between configuration options and boot options is that configuration options can be modified at runtime. Configuration options are used to tune performance or change functionality.

Configuration options have two additional layers of properties source on top of boot options:

Options source	Description
Session level	Options modified during runtime and stored in Drill memory until the user session ends. Not all Drill configuration options can be set at the session level. Check the <code>accessibleScopes</code> of the option in the system table <code>options</code> .
System level	Options modified during runtime, shared across all the Drill cluster, and persisted between restart of the Drillbits. System-level options are stored in persistent storage . By default, ZooKeeper stores the options. System-level options can only be set by admins. System-level options are bonded to the Drill cluster ID and preserved even after Drill is uninstalled from a node.

Configuration options are divided into two types: `internal` and `public`. Internal options are intended to be used by Drill developers and are not expected to be used in production.

You can find the complete list of internal configuration options in the `internal_options` [system table](#). For example:

```

apache drill> select * from sys.internal_options limit 10;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
|          name          | kind |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| accessibleScopes | val  | status | optionScope |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| description |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| drill.exec.hashjoin.mem_limit | BIGINT |
SYSTEM | 0 | DEFAULT | BOOT | Enforces the maximum
memory limit for the Hash Join operator (if non-zero); used for testing
purposes. Defa... |
| drill.exec.rpc.fragrunner.timeout | BIGINT |
SYSTEM | 10000 | DEFAULT | BOOT |
|
| drill.exec.stats.logging.batch_size | BIT |
SYSTEM_AND_SESSION | false | DEFAULT | BOOT | Enables batch size
statistics logging. |
| drill.exec.stats.logging.enabled_operators | VARCHAR |

```

```

SYSTEM_AND_SESSION | all | DEFAULT | BOOT | Controls the list of
operators for which batch sizing statistics should be enabled. |
| drill.exec.stats.logging.fine_grained.batch_size | BIT |
SYSTEM_AND_SESSION | false | DEFAULT | BOOT | Enables fine-grained
batch size statistics logging. |
...

```

You can find the complete list of public configuration options in the options system table or in the Drill Web UI. For example:

```

apache drill> select * from sys.options;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
|          name          | kind | accessibleScopes |
| val | status | optionScope | description |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| debug.validate_iterators | BIT | ALL |
| false | DEFAULT | BOOT |
|
| debug.validate_vectors | BIT | ALL |
| false | DEFAULT | BOOT |
|
| drill.exec.functions.cast_empty_string_to_null | BIT | ALL |
| false | DEFAULT | BOOT | In a text file, treat empty fields as
NULL values instead of empty string. |
| drill.exec.hashagg.fallback.enabled | BIT | ALL |
| false | DEFAULT | BOOT | Hash Aggregates ignore memory limits when
enabled (true). When disabled (false), Hash Aggregates fail when ... |
| drill.exec.hashjoin.fallback.enabled | BIT | ALL |
| false | DEFAULT | BOOT | Hash Joins ignore memory limits when this
option is enabled (true). When disabled (false), Hash Joins fail ... |
...

```

IMPORTANT: If a Drill option has the DEFAULT status, it means the value is set in boot options and was not overridden in the system or session level.

Setting the Configuration Option in the Boot Scope

Be careful if you want to set a configuration option in the boot options (BOOT scope). To set the option in boot options, you need to add the `drill.exec.options` suffix to the name of the configuration option you see in the name column of the options system table. For example:

```
alter system set 'planner.enable_nljoin_for_scalar_only' = false;
```

But use the following entry in the `drill-override.conf` file:

```
drill.exec.options.planner.enable_nljoin_for_scalar_only=false
```

Setting System Options

You can set system options by using the SQL `alter system` command in the Drill Web UI or by using the REST API. For example:

```
apache drill> alter system set 'planner.enable_nljoin_for_scalar_only' =
false;
```

```

+-----+-----+
| ok | summary |
+-----+-----+
| true | planner.enable_nljoin_for_scalar_only updated. |
+-----+-----+

```

Setting Session Options

You can set session options by using the SQL `alter session` command. The syntax is similar to `alter system`. For example:

```

apache drill> alter session set 'store.parquet.flat.reader.bulk' = false;
+-----+-----+
| ok | summary |
+-----+-----+
| true | store.parquet.flat.reader.bulk updated. |
+-----+-----+

```

Starting from EEP 9.3.0, you can set the session option by adding the option to either the JDBC connection string or JDBC connection properties.

To add a session option to the JDBC connection string, add a parameter in the format `session.option.name=value` separated with a semicolon. For example:

```

jdbc:drill:drillbit=localhost;auth=maprsasl;planner.enable_join_optimization=false

```

To add a session option to the JDBC Connection properties, put the option to the properties, using the option name as a key, and a String value as a value. Here is an example code snippet:

```

String connectionString = "jdbc:drill:zk=node1.cluster.com:5181/drill/
drill-cluster.com;auth=maprsasl;";
Properties connectionProperties = new Properties();
connectionProperties.put("planner.enable_join_optimization", "false");
Connection connection = DriverManager.getConnection(connectionString,
connectionProperties);

```

Working with Drill

For general information about working with Drill, refer to the following key topics:

Connecting Drill to Data Sources

Choose and configure storage plugins to enable Drill to connect to a data source.

Drill serves as a query layer that connects to data sources through storage plugins. A storage plugin is a software module for connecting Drill to data sources. A storage plugin typically optimizes execution of Drill queries, provides the location of the data, and configures the workspace and file formats for reading data.

What you can do with Storage Plugins

Several storage plugins are installed with Drill that you can configure to suit your environment. Through a storage plugin, Drill connects to a data source, such as a database, a file on a local or distributed filesystem, or a Hive metastore. See the [Drill Storage and Format Plugin Support Matrix](#).

You can modify the default configuration of a storage plugin and give the new configuration a unique name. This document refers to Y as a different storage plugin, although it is actually just a reconfiguration of original interface.

On the Storage tab of the Web Console, you can view and reconfigure a storage plugin if you have permission. You can access each node running a Drillbit by starting the Drill Web Console. The way you [start the Drill Web Console](#) depends on your security setup.

When you install Drill using the `mapr-drill` package, storage plugin configurations are available for the following data sources:

- file system
- [HPE Data Fabric Database](#)

NOTE: To access HPE Data Fabric Database tables, use the dfs storage plugin with the [maprdb format plugin](#).

- [Hive](#)
- [Kafka](#)

Connecting Drill to HBase

As of the Core 6.0 and Drill 1.11, HBase is no longer supported, therefore the communication path between Drill and HBase is also not supported. If you have an hbase storage plugin configured in Drill, you should disable it.

Default Storage Plugin Configurations

The Drill documentation describes the [attributes and definitions](#) that you can configure for storage plugins, except for the HPE Data Fabric Database format. See [HPE Data Fabric Database Format Plugin for Drill](#).

The Drill Web Console includes some default storage plugin configurations. The following table lists the default configurations and their descriptions:

Instance	Description
cp	Points to a JAR file in the Drill classpath that contains the Transaction Processing Performance Council (TPC) benchmark schema TPC-H that you can query.
dfs	Points to file system by default. Drill automatically configures this instance when you install Drill in a the cluster. Includes a maprdb format plugin for HPE Data Fabric Database.
hive	Integrates Drill with the Hive metadata abstraction of files, HPE Data Fabric Database, and libraries to read data and operate on SerDes and UDFs.

When you add or update a storage plugin configuration on one Drill node in a Drill cluster, Drill broadcasts the information to all of the other Drill nodes. All nodes have identical storage plugin configurations. You do not need to restart any Drillbits when you add or update a storage plugin configuration.

Configuring Storage Plugin Instances

You can add, remove, or update Drill storage plugin configurations using the Web Console. The following image shows the default storage plugin configurations in the Drill Web UI:

The screenshot shows the Apache Drill web interface. At the top is a black header with the 'Apache Drill' logo on the left and a hamburger menu icon on the right. Below the header, the page is divided into three main sections:

- Enabled Storage Plugins:** This section contains a table with two rows. The first row is for the 'cp' plugin, with 'Update' and 'Disable' buttons. The second row is for the 'dfs' plugin, also with 'Update' and 'Disable' buttons.
- Disabled Storage Plugins:** This section contains a table with three rows. The first row is for the 'hbase' plugin, with 'Update' and 'Enable' buttons. The second row is for the 'hive' plugin, with 'Update' and 'Enable' buttons. The third row is for the 'mongo' plugin, with 'Update' and 'Enable' buttons.
- New Storage Plugin:** This section has a text input field labeled 'Storage Name' and a 'Create' button below it.

If you click **Update** next to `dfs`, the following default configuration appears :

```
{
  "type": "file",
  "enabled": true,
  "connection": "maprfs:///",
  "workspaces": {
    "root": {
      "location": "/",
      "writable": false,
      "defaultInputFormat": null
    },
    "tmp": {
      "location": "/tmp",
      "writable": true,
      "defaultInputFormat": null
    }
  }
},
```

```

    "formats": {
      "psv": {
        "type": "text",
        "extensions": [
          "tbl"
        ],
        "delimiter": "|"
      },
      "csv": {
        "type": "text",
        "extensions": [
          "csv"
        ],
        "delimiter": ","
      },
      "tsv": {
        "type": "text",
        "extensions": [
          "tsv"
        ],
        "delimiter": "\t"
      },
      "parquet": {
        "type": "parquet"
      },
      "json": {
        "type": "json"
      },
      "maprdb": {
        "type": "maprdb"
      }
    }
  }
}

```

The dfs configuration includes the storage plugin type, connection information, default workspaces, and file formats that the data source supports. You can add and remove workspaces and file formats.

Changing the Connection Attribute

You can also change the connection if you want the configuration to point to a different cluster.

By default, Drill connects to the cluster that the Drill node belongs to. You do not need to modify the connection unless you want to connect Drill to a different cluster. To connect to a different cluster, edit the connection to include the name of the cluster that you want to connect to.

Example:

```
"connection": "maprfs://<cluster_name>/"
```

Drill Storage and Format Plugin Support Matrix

You can deploy Drill without Hadoop in a standalone configuration on a single node, however multi-node standalone cluster deployments of Drill are not supported. Note that Drill itself does not require Hadoop.

The following table lists the supported and unsupported data sources and formats in Drill:

Data Source	Storage Plugin Type	Formats	Supported
file system	dfs	Text (CSV, TSV, PSV)	Yes
		Parquet	Yes
		JSON	Yes

		Avro	No
HPE Data Fabric Database	dfs	Binary	Yes
		JSON	Yes
HBase	hbase	Binary	Yes
Hive	hive	Text (CSV, TSV, PSV)	Yes
		Parquet	Yes
		JSON	Yes
		Avro	Yes
		Other Hive built-in SerDes	Yes (Not recommended due to the memory overhead and performance implications.)
S3	s3	Supports the same formats as the dfs storage plugin.	Yes
MongoDB	mongodb	N/A	No
RDBMS	jdbc	N/A	No
Kudu	kudu	N/A	No
Kafka	kafka	JSON	Yes
OpenTSDB	openTSDB	N/A	 NOTE: The openTSDB storage plugin is not officially supported. See OpenTSDB Storage Plugin for more information.

maprdb Format Plugin for Drill

Drill supports access to HPE Data Fabric Database JSON and binary tables through the maprdb format plugin.

When you install Drill, the maprdb format is automatically defined within the default dfs storage plugin configuration to make HPE Data Fabric Database a consumable data source for Drill. You can access the dfs storage plugin configuration from the Storage page in the [Drill Web UI](#).

When you install Drill, you will see some options specific to the maprdb format plugin that you can change or configure. You can modify these options in the following places:

- [dfs storage plugin configuration](#)
- [drill-override.conf file](#)
- [SET command](#)

For additional information about storage plugins, see [Plugin Configuration Basics](#).

Modifying the maprdb Format Settings within the dfs Storage Plugin Configuration

You can add or modify certain maprdb format plugin settings within the dfs storage plugin configuration on the Storage page in the Drill Web UI.

The following table lists the maprdb format options that you can set within the dfs storage plugin configuration:

Option	Description	Value
allTextMode	When enabled, Drill reads all values as type varchar. Useful when the underlying data set has type values of mixed scalar types, such as integers, floating point, varchars, date, time, and timestamp. Disabled by default.	true false
disableCountOptimization	When enabled, this option disables optimization for queries with the COUNT (*) aggregate function. Disabled by default.	true false
enablePushdown	When enabled, Drill pushes down filters to HPE Data Fabric Database. Disabling this option is not recommended unless you intend to use it for troubleshooting purposes. Enabled by default.	true false
ignoreSchemaChange	When enabled, Drill ignores schema changes. Disabled by default.	true false
nonExistentColumnsProjection	When enabled, Drill can distinguish between null and non-existent fields. Disabled by default.	true false
readNumbersAsDouble	When enabled, Drill reads all numeric values as type double. Useful when the underlying data set has type values of mixed numeric types, such as integers and floating point. Disabled by default.	true false
readTimestampWithZoneOffset	When enabled (set to 'true'), Drill converts timestamp values from UTC to local time zone when reading the values from Data Fabric Database (maprdb). Disabled (set to 'false') by default. Does not impact the store.hive.maprdb_json.read_timestamp_with_timezone_offset setting.	true false

The following example configuration shows you how to include the options in the maprdb format configuration within the dfs storage plugin configuration:

```
{
  "type": "file",
  "enabled": true,
  "connection": "maprfs:///",
  "config": null,
  "workspaces": {
    "root": {
      "location": "/",
      "writable": false,
      "defaultInputFormat": "maprdb",
      "allowAccessOutsideWorkspace": false
    },
    "formats": {
      "maprdb": {
        "type": "maprdb",
        "allTextMode": true,
        "disableCountOptimization": true,

```

```

    "enablePushdown": false
  },
  "parquet": {

      "json"
    ]
  }
}

```

See [Plugin Configuration Basics](#) and [File System Storage Plugin](#) for more information.

Overriding Default maprdb Format Plugin Settings in drill-override.conf

You can override the default maprdb format plugin settings that control the level of parallelism in Drill and the media type in the `drill-override.conf` file.

To override the default maprdb format plugin settings, add the options to the `format-maprdb.json` configuration in the `/opt/mapr/drill/drill-<version>/conf/drill-override.conf` file, as shown:

```

format-maprdb: {
  json: {
    scanSizeMB: 512,
    restrictedScanSizeMB: 4096
    mediaType: HDD
  }
}

```

The following sections describe how to modify the options in the configuration shown above:

Configuring the Level of Parallelism in Drill

The size of data chunks and number of minor fragments affect the level of parallelism in Drill. When querying JSON tables, Drill creates minor fragments that scan the chunks of data that HPE Data Fabric Database passes to Drill. Minor fragments are logical units of work that determine the level of parallelism in Drill. The level of parallelism increases with the number of minor fragments. See [Drill Query Execution](#) for more information about how Drill executes a query.

Modifying the Size of Data Chunks

The `format-maprdb.json.scanSizeMB` option changes the size of data chunks that HPE Data Fabric Database passes to Drill when querying JSON tables. Drill creates approximately one minor fragment per data chunk when querying JSON tables. For example, if a table has 4 GB of data and the chunk size is set to 128 MB, Drill creates approximately 32 minor fragments to scan the data chunks.

The default setting for data chunks is 128 MB, however you can override this default in the `drill-override.conf` file. The value of the `format-maprdb.json.scanSizeMB` option can range from 32 MB to 8192 MB (8 GB). Adjust the setting based on the size of your tables. Use a higher setting for larger tables and a lower setting for smaller tables. The right setting can reduce latency and increase throughput.

Modifying the Number of Minor Fragments Created

The `format-maprdb.json.restrictedScanSizeMB` option determines the number of minor fragments that Drill creates to scan the data and do the join-back to a JSON table when executing a non-covering index plan.

The default setting for this option is 4096 MB, however you can override this setting in the `drill-override.conf` file. The value of this option can range from 32 MB to 8192 MB (8 GB). Adjust the setting based on the

size of your tables, keeping in mind that due to the random I/O nature of the join-back, a smaller setting (increased parallelism) may not necessarily increase throughput.

NOTE: The planner `.slice_target` option in Drill determines the number of minor fragments that can run in parallel. See [Modifying Query Planning Options](#) for more information.

Configuring the Media Type

Drill is optimized for SSDs, however HPE Data Fabric Database and Drill can run on HDDs. If you run Drill and HPE Data Fabric Database on HDDs, use the `mediaType` option in the `drill-override.conf` file to override the default setting. The `mediaType` option accepts HDD or SSD (default) as the value. Specify SSD or HDD in upper case as the value in the `drill-override.conf` file.

Drill Options for the maprdb Format Plugin

You can enable certain Drill options for the maprdb format plugin from the Options page in the Drill Web UI or from the command line using the SET and ALTER SYSTEM commands.

To enable the options from the Drill Web UI, go to `http(s)://<drill-hostname-or-ip-address>:8047`, and select **Options** in the menu bar. Alternatively, enable options from the command line using the [SET](#) or [ALTER SYSTEM](#) commands, as shown:

```
SET `store.hive.maprdb_json.optimize_scan_with_native_reader` = true;
```

You can enable the following Drill options for the maprdb format plugin:

store.hive.maprdb_json.optimize_scan_with_native_reader	Starting in Drill 1.14 (EEP 6.0), enable the <code>store.hive.maprdb_json.optimize_scan_with_native_reader</code> option if you want Drill to use the native Drill reader to read Hive MapR-DB JSON tables . When you enable the native Drill reader, Drill typically performs faster reads of data and applies filter pushdown optimizations.
store.hive.maprdb_json.read_timestamp_with_timezone_offset	Starting in Drill 1.16, you can enable Drill to read timestamp values with a timezone offset when the hive plugin is used and the Drill native MapRDB JSON reader is enabled through the <code>store.hive.maprdb_json.optimize_scan_with_native_reader</code> option.

IMPORTANT: Internally, Drill stores timestamp values in UTC format, for example 2018-01-01T20:12:12.123Z. When you enable the timezone offset option, select on a table returns different timestamp values. If you filter on timestamp values when this option is enabled, you must include the new timestamp value in the filter condition. For example, look at the timestamp values when the `store.hive.maprdb_json.read_timestamp_with_timezone_offset` option is disabled (set to 'false'):

```
select * from dfs.`/tmp/timestamp`;
-----
_id      datestring      datetimestamp
-----
1        2018-01-01 12:12:12.123    2018-01-01 20:12:12.123
2        9999-12-31 23:59:59.999    10000-01-01 07:59:59.999
-----
```

When the option is enabled (set to 'true'), you can see the difference in the timestamp values returned:

```
select * from dfs.`/tmp/timestamp`;
-----
_id      datestring      datetimestamp
-----
1        2018-01-01 12:12:12.123    2018-01-01 12:12:12.123
2        9999-12-31 23:59:59.999    9999-12-31 23:59:59.999
-----
```

When the option is enabled, queries that filter on timestamp values must include the new timestamp value in the filter condition, as shown:

```
select * from dfs.`/tmp/timestamp` where datetimestamp=timestamp
'2018-01-01 12:12:12.123';
-----
_id      datestring      datetimestamp
-----
1        2018-01-01 12:12:12.123    2018-01-01 12:12:12.123
-----
```

Notice that the WHERE clause uses the `2018-01-01 12:12:12.123` format versus the `2018-01-01 20:12:12.123` format.

HPE Data Fabric Database Tables

The `maprdb` format plugin enables you to query binary and JSON tables like you would query files in a file system because HPE Data Fabric Database and the file system share the same namespace.

Binary tables differ from JSON tables in that they store a multi-dimensional map in which both keys and values are a sequence of bytes. JSON tables store [OJAI documents](#). JSON tables support rich data types, including complex and repeated types, that enable database servers to evaluate filter conditions for optimized query execution. Binary tables can pose performance limitations because the table columns do not contain the necessary type information.

You can query tables stored in any directory in HPE Data Fabric Database using the same syntax that you use to select from files in the file system. Instead of including the path of a file in a query, you include the table path. The user running the query must have [read permission](#) to access the table.

 **NOTE:** HPE Data Fabric Database is a case sensitive data source. To ensure that your queries return results, use the case that corresponds to the column names in the JSON tables and views that you query. For example, if you query the “age” column in a JSON table, the query must reference the column as “age” and cannot reference the column as “AGE” or the query will not return results. If you have a dataset where a column name has mixed cases, such as “age” and “AGE,” cleanse the data set so column names consist of one case and then reimport the data into the table to ensure a complete result set when you query the column.

The following sections describe the types of tables that HPE Data Fabric Database supports, provide examples of Drill queries on each type of table, and show you how to load data into a JSON table from JSON files.

JSON Tables

A JSON table is a collection of JSON documents stored in an optimized format in HPE Data Fabric Database. JSON tables support complex schema, like JSON files including nested and repeated types, but with additional support for more [data types](#).

JSON tables leverage the [OJAI API](#) to natively support [Drill data types](#) making it possible for HPE Data Fabric Database to recognize, store, and interpret each of the Drill data types. This alleviates the need to encode data when an application writes to tables or use conversion functions when running queries against tables. For example, if a number or date is stored in a JSON table, you do not need to use the CAST or [CONVERT](#) functions for the query to return the actual values.

HPE Data Fabric Database's native support for Drill data types enables Drill to push down filters and projections to HPE Data Fabric Database which optimizes performance.

Querying a JSON Table

Querying JSON tables is simpler than querying binary tables because you do not have to include conversion functions in the queries to change the byte sequences into specific data types, and you do not have to include column families.

The following query examples show query results on a JSON table named “students” in HPE Data Fabric Database. Note that Drill returns human readable values without having to include the CAST or CONVERT functions in the queries.

Example 1

```
SELECT * FROM dfs.`/user/root/json/students`;
```

_id	date	name	state	street	zipcode
student1	2016-01-15	Alice	CA	123 Ballmer Av	12345
student2	2016-03-08	Bob	CA	1 Infinite Loop	12345
student3	2015-12-22	Frank	CA	435 Walker Ct	12345
student4	2015-09-15	Mary	CA	56 Southern Pkwy	12345

4 rows selected (0.233 seconds)

Example 2

```
SELECT _id, `date`, name, state, street, zipcode FROM dfs.`/user/root/json/students`;
```

_id	date	name	state	street	zipcode
student1	2016-01-15	Alice	CA	123 Ballmer Av	12345.0
student2	2016-03-08	Bob	CA	1 Infinite Loop	12345.0
student3	2015-12-22	Frank	CA	435 Walker Ct	12345.0
student4	2015-09-15	Mary	CA	56 Southern Pkwy	12345.0

```
+-----+-----+-----+-----+-----+-----+
4 rows selected (1.033 seconds)
```

Loading JSON Documents into a HPE Data Fabric Database Table with dbshell Commands

You can use the INSERT command in the `mapr dbshell` to load JSON documents into a HPE Data Fabric Database table.

The INSERT command is useful when inserting a small number of JSON documents into a JSON table.

NOTE: Alternatively, you can put JSON documents in a flat text file and use the `mapr importJSON` command to import the JSON documents into a table. The `mapr importJSON` command is useful when you need to insert many documents into a table. Refer to [HPE Data Fabric Database JSON ImportJSON](#) on page 7438 for instruction.

NOTE: The examples in this document use the student data in the [Querying HBase Tutorial](#) to recreate the binary “students” table as a JSON table in HPE Data Fabric Database.

To load JSON documents into a HPE Data Fabric Database table through the `mapr dbshell`, complete the following steps:

1. Run the following command to start the `mapr dbshell`:

```
mapr dbshell
```

2. Run the following command to create a table:

```
create <table-name>
```

Example:

```
create students
```

NOTE: By default, the table is stored in the default directory. The default directory is the current directory on the Data Fabric file system, which is set to the user's home directory when the `mapr dbshell` starts. Include a file path, as shown, if you do not want the table stored in the default directory:

```
create /file/path/table-name
```

3. Load the JSON documents into the table using the INSERT command, as shown:

```
insert <table-name> --value '{JSON-document}'
```

Example:

```
insert students --value '{"_id":"student1", "name":"Alice",
"street":"123 Ballmer Av", "zipcode":12345, "state":"CA"}'
insert students --value '{"_id":"student2", "name":"Bob", "street":"1
Infinite Loop", "zipcode":12345, "state":"CA"}'
insert students --value '{"_id":"student3", "name":"Frank",
"street":"435 Walker Ct", "zipcode":12345, "state":"CA"}'
insert students --value '{"_id":"student4", "name":"Mary", "street":"56
Southern Pkwy", "zipcode":12345, "state":"CA"}'
```

4. Run the following command to verify that the table was created:

```
find <table-name>
```

Example:

```
find students
```

5. Run the following command to close the `mapr dbshell`:

```
exit
```

6. If you need to start or restart Drill, run the following command:

```
maprccli node services -name drill-bits -action start|restart -nodes  
<space-separated-list-of-drill-hostnames>
```

7. Run the following command to start the Drill shell (SQLLine):

```
sqlline
```

You can query the HPE Data Fabric Database JSON table from the Drill shell. If you did not include a file path when you created the table, the table was created in the current directory on the Data Fabric File system, which is set to the user's home directory. For example, the following query specifies the default directory if the root user created the table without indicating a file path:

```
SELECT * FROM dfs.`/user/root/table-name`;
```

Example:

```
SELECT * FROM dfs.`/user/root/students`;
```

If the user created the table in a specific directory, the query must include the directory in which the table was created, as shown:

```
SELECT * FROM dfs.`/file/path/table-name`;
```

Binary Tables

[Binary tables](#) store data in a flat table structure where the table consists of columns and column values. Every field in a binary table is stored as a sequence of bytes.

[Binary tables](#) do not store data type information. You manage the encoding for binary tables when storing data and then convert the sequence of bytes into a specific data type using the `CAST` or [CONVERT functions](#) when you run queries against the tables.

For example, if a string is stored in binary format, such as a UTF-8 encoded string, you must use the `CAST` function for the query to return a string type. If an integer is stored in binary format, such as 4-byte little endian encoding, you must use the `CONVERT` function for the query to return the integer value instead of the 4-byte sequence.

Querying a Binary Table

The following examples, from the [Querying HBase Tutorial](#), display query results when the binary table `/user/root/binary/students` with two column families, `account` and `address`, is queried without using a conversion function to convert the binary table data into specific data types.

Example 1

```
SELECT * FROM `/user/root/binary/students` students;
```

```
+-----+-----+-----+-----+
| row_key | account |
| address |         |
+-----+-----+-----+-----+
| [B@78dfa1ed | {"date":"MjAxNi0wMS0xNQ==", "name":"QWxpY2U="} |
{"state":"Q0E=", "street":"MTIzIEJhbGxtZXIgcXY=", "zipcode":"MTIzNDU="} |
| [B@22000c9a | {"date":"MjAxNi0wMy0wOA==", "name":"Qm9i"} |
{"state":"Q0E=", "street":"MSBJbmZpbml0ZSBMb29w", "zipcode":"MTIzNDU="} |
| [B@313b63e6 | {"date":"MjAxNS0xMi0yMg==", "name":"RnJhbms="} |
{"state":"Q0E=", "street":"NDM1IFdhbGtldDdA==", "zipcode":"MTIzNDU="} |
| [B@321baa4a | {"date":"MjAxNS0wOS0xNQ==", "name":"TWYyeQ=="} |
{"state":"Q0E=", "street":"NTYgU291dGhlcm4gUGt3eQ==", "zipcode":"MTIzNDU="} |
+-----+-----+-----+-----+

4 rows selected (0.612 seconds)
```

In example 2, using the `CONVERT_FROM` and `CAST` functions in a query on the same table converts the binary table data to typed data.

Example 2

```
SELECT CONVERT_FROM(row_key, 'UTF8') AS studentid,
CONVERT_FROM(students.account.name, 'UTF8') AS name,
CONVERT_FROM(students.address.state, 'UTF8') AS state,
CONVERT_FROM(students.address.street, 'UTF8') AS street,
CONVERT_FROM(students.address.zipcode, 'UTF8') AS zipcode,
CAST(students.account.`date` as date) AS `date` FROM dfs.`/user/root/binary/
students` students;
```

```
+-----+-----+-----+-----+-----+-----+-----+
| studentid | name | state | street | zipcode | date |
+-----+-----+-----+-----+-----+-----+
| student1 | Alice | CA | 123 Ballmer Av | 12345 | 2016-01-15 |
| student2 | Bob | CA | 1 Infinite Loop | 12345 | 2016-03-08 |
| student3 | Frank | CA | 435 Walker Ct | 12345 | 2015-12-22 |
| student4 | Mary | CA | 56 Southern Pkwy | 12345 | 2015-09-15 |
+-----+-----+-----+-----+-----+-----+

4 rows selected (0.702 seconds)
```

Working with Joda-Time Format

Describes queries on Joda-Time formatted columns and how to include annotations for successful queries.

Drill cannot read timestamp values in a `maprdb` column if the column is formatted in Joda-Time. You cannot `CAST` Joda-Time columns or values to another type unless you annotate the Joda-Time column with `"$date"` for timestamp values or `"$dateDay"` for date values, as shown:

```
"order_received_ts" : { "$date": "1992-04-05T02:15:16Z"}
```

NOTE: The following set of annotations were used for internal purposes, but they do not provide any additional SQL benefits in Drill. Instead of using these annotations, you can CAST the data types.

```
$binary
$numberByte
$decimal
$numberFloat
$numberInt
$interval
$numberLong
$numberShort
$time
```

Querying Joda-Time Formatted Columns without Annotation

The following examples show you the results of two queries on a JSON database table (t2) with a Joda-Time formatted column, `order_received_ts`, that does not have the "\$date" or "\$dateDay" annotation. Table t2 contains the following data:

```
maprdb mapr:> find /test01/t2
{"_id":"472271675972670","amount":10433.28,"delivery_method":"TRUCK","discount_rate":10.03,"instructions":"DELIVER IN PERSON","notes":"ccording to the foo","order_date":"1993-09-11","order_received_ts":"1992-04-05T02:15:16Z","product_category_id":6,"quantity":6,"ship_date":"1993-09-21","store_id":"8134660","tax_rate":10.06,"type_code":"F"}
1 document(s) found.
```

The following query filters on `order_received_ts` and casts the value to the timestamp data type:

```
apache drill> select _id, order_received_ts from dfs.`/test01/t2` where
order_received_ts > cast('1992-04-05 01:15:16' as timestamp);
+--+
|  |
+--+
+--+
No rows selected (0.402 seconds)
```

The following query casts the `order_received_ts` column to timestamp:

```
apache drill> select _id, cast(order_received_ts as
timestamp), customer_id, order_date from dfs.`/test01/t2`;
Error: SYSTEM ERROR: DateTimeParseException: Text '1992-04-05T02:15:16Z'
could not be parsed, unparsed text found at index 10

Fragment 0:0

Please, refer to logs for more information.

[Error Id: 039a92d4-43d6-4561-80b5-d87a588f5b10 on mycluster:31010]
(state=,code=0)
apache drill>
```

Both queries return unexpected results; however, adding an annotation can resolve the issue.

Adding an Annotation to Joda-Time Formatted Columns

You will need to update the table or recreate the table to add the annotation. You can do this through the `maprdb` shell or you can update the data in a JSON file and then import the JSON file into a `maprdb` JSON table. In this example, the annotation is added to a JSON file and then imported into a JSON table.

To add the annotation to the `order_received_ts` column:

1. Update the JSON file with the annotation:

```
{
  "_id" : "472271675972670",
  "store_id" : "8134660",
  "quantity" : 6,
  "product_category_id" : 6,
  "amount" : 10433.28,
  "discount_rate" : 10.03,
  "tax_rate" : 10.06,
  "type_code" : "F",
  "order_date" : {"$dateDay": "1993-09-11"},
  "ship_date" : "1993-09-21",
  "order_received_ts" : {"$date": "1992-04-05T02:15:16Z"},
  "instructions" : "DELIVER IN PERSON",
  "delivery_method" : "TRUCK",
  "notes" : "ccording to the foo"
}
```

2. Put the JSON file in a mapr directory:

```
hadoop fs -put t2.json /user/mapr/.
```

3. Create the JSON database table:

```
maprcli table create -path /test01/t2 -tabletype json
```

4. Import the JSON file into the JSON table:

```
mapr importJSON -src /user/mapr/t2.json -dst /test01/t2 -mapreduce false
```

Now that the annotation is added, Drill queries against the table (t2) run successfully and return the expected results:

```
apache drill> select _id, order_received_ts from dfs.`/test01/t2` where
order_received_ts > cast('1992-04-05 01:15:16' as timestamp);
+-----+-----+
|      _id      | order_received_ts |
+-----+-----+
| 472271675972670 | 1992-04-05T02:15:16.000Z |
+-----+-----+
1 row selected (0.334 seconds)
```

```
apache drill> select _id, order_date from dfs.`/test01/t2` where
order_date > cast('1993-08-10' as date);
+-----+-----+
|      _id      | order_date |
+-----+-----+
| 472271675972670 | 1993-09-11 |
+-----+-----+
1 row selected (0.156 seconds)
apache drill>
```

Configuring the Hive Storage Plugin

About this task

You can connect Drill to a Hive data source through the hive storage plugin configuration in the Drill Web UI. After configuration, use Drill to query data stored in Hive.

Drill can work with only one version of Hive in a given cluster. To access Hive tables using custom SerDes or InputFormat/OutputFormat, all nodes running Drill must have the SerDes or InputFormat/OutputFormat JAR files in the <drill_installation_directory>/jars/3rdparty location.

To query across multiple versions of Hive, install each version of Hive on a separate Drill cluster. You must define separate storage plugins, each corresponding to the specific Hive version of the metastore.

NOTE: In [EEP 6.0](#), Drill requires Hive version 2.3.3-mapr or later to successfully query Hive data sources.

Configuring a Hive Remote Metastore

A remote Hive metastore configuration runs as a separate service outside of Hive. The metastore service communicates with the Hive database over JDBC. Point Drill to the Hive metastore service address, and provide the connection parameters in the Hive storage plugin configuration to configure a connection to Drill. The Hive storage plugin (located on the **Storage** tab in the Drill Web UI) has the following default configuration if you install Drill:

```

{
  "type": "hive",
  "enabled": true,
  "configProps": {
    "hive.metastore.uris": "",
    "javax.jdo.option.ConnectionURL": "jdbc:derby;;databaseName=../
sample-data/drill_hive_db;create=true",
    "hive.metastore.warehouse.dir": "/tmp/drill_hive_wh",
    "fs.default.name": "file:///",
    "hive.metastore.sasl.enabled": "false",
    "datanucleus.schema.autoCreateAll": "true"
  }
}

```

Complete the following steps to modify the default Hive storage plugin configuration for your file system environment:

Procedure

1. Verify that Hive is running.
2. Issue the following command to start the Hive metastore service on the system specified in the `hive.metastore.uris`: `hive --service metastore`
3. [Start the Drill Web UI](#).
4. Select the **Storage** tab. If [Web UI security](#) is enabled, you must have administrator privileges to perform this step.
5. In the list of disabled storage plugins in the Drill Web UI, click **Update** next to Hive.
6. Update the following Hive storage plugin parameters to match the system environment:
 - `"hive.metastore.uris"`
 - `"jdbc:<database>://<host:port>/<metastore database>"`

- Change the default location of files to suit your environment. For example, change "fs.default.name": "file:/// " to the file system location: maprfs:///
- To run Drill and Hive in a secure cluster, change the "hive.metastore.sasl.enabled" parameter to "true".
- Change the "datanucleus.schema.autoCreateAll" property setting for your system environment. After it is enabled, "datanucleus.schema.autoCreateAll" initializes the Hive metastore schema.
 - In a production environment, remove the "datanucleus.schema.autoCreateAll" property from the Hive storage plugin configuration; the property is not required because the preferred schema information is already created for the Hive metastore service.
 - In a test environment with an embedded Hive metastore, you can disable (set to false) this property after the first query on the Hive data source that you submit from Drill. Alternatively, use the [Hive schema tool](#) to initialize or upgrade the Hive metastore schema. Using the Hive schema tool is recommended for queries on transactional tables. Run the schematool command as an initialization step:

```
/opt/mapr/hive/hive-<version>/bin/schematool -dbType
<databaseType> -initSchema
```

7. Click **Enable** in the Web UI to enable the Hive storage plugin configuration.

Configuring the Kafka Storage Plugin

To configure Kafka as a data source in Drill, update the <drill_home>/jars/3rdParty directory with the required JAR files, restart Drill, and configure the kafka storage plugin in the Drill Web UI.

Verify that the nodes in your cluster meet the requirements and then complete the steps listed.

Requirements

The Kafka storage plugin requires:

- HPE Data Fabric 7.0 or later cluster
- Drill 1.16.1 or later installed on nodes
- The HPE Data Fabric Kafka client package (kafka-2.1.1, 2.6.1, or later) installed on at least one node. The Kafka client installation provides the following kafka JAR files that you copy into the <drill_home>/jars/3rdParty directory (step 4):

NOTE: Kafka 2.1.1 is used as an example. The version of your Kafka JAR files may differ.

- Kafka-2.1.1
 - kafka_2.11-2.1.1.200-mapr-710.jar
 - kafka-clients-2.1.1.200-mapr-710.jar
- Kafka-2.6.1 (if you have eep-800 or later installed)
 - kafka_2.13-2.6.1.0-eep-800.jar
 - kafka-clients-2.6.1.0-eep-800.jar
 - kafka-eventstreams-0.1.0.0-eep-800.jar

Steps

Complete the following steps to query Kafka Streams from Drill:

NOTE: Do not perform step 2 if you installed Drill using the RPM or Debian packages. Step 2 is only required if you installed Drill using a TAR file.

1. Remove the specified JAR files from the `<drill_home>/jars/3rdParty` directory based on the Drill installation method:
 - If you installed Drill using RPM or Debian packages, only remove JAR files that start with kafka, such as `kafka-clients-<version>.jar` and `kafka_<version>.jar`, from the `<drill_home>/jars/3rdParty` directory.
 - If you installed Drill using a TAR file, remove all the JAR files that start with mapr and kafka, such as `maprdb-<version>-mapr.jar`, `maprfs-<version>-mapr.jar`, `kafka_<version>-mapr.jar`, and `kafka-clients-<version>.jar`, from the `<drill_home>/jars/3rdParty` directory.
2. (Only perform this step if you installed Drill using a TAR file.) Copy the following JAR files from the `/opt/mapr/lib` directory into `<drill_home>/jars/3rdParty` directory:
3. Copy the `mapr-streams-6.2.0.0-mapr.jar` file from the `/opt/mapr/lib` directory into the `<drill_home>/jars/3rdParty` directory.
4. Copy the following kafka JAR files from the `/opt/mapr/kafka/kafka-*/libs` directory into the `<drill_home>/jars/3rdParty` directory:

NOTE: Kafka 2.1.1 is used as an example. The version of your Kafka JAR files may differ.

- Kafka-2.1.1
 - `kafka_2.11-2.1.1.200-mapr-710.jar`
 - `kafka-clients-2.1.1.200-mapr-710.jar`
 - Kafka-2.6.1 (if you have eep-800 or later installed)
 - `kafka_2.13-2.6.1.0-eep-800.jar`
 - `kafka-clients-2.6.1.0-eep-800.jar`
 - `kafka-eventstreams-0.1.0.0-eep-800.jar`
5. Issue the following command to restart Drill:

```
$ maprcli node services -name drill-bits -action restart -nodes <node
hostnames separated by a space>
```

6. Log in to the [Drill Web UI](#), and configure the kafka storage plugin. See [Kafka Storage Plugin](#) for instructions.

NOTE: When configuring the kafka storage plugin, you must also include the following parameter in the storage plugin configuration:

```
"streams.consumer.default.stream": "<path-to-stream>"
```

Usage Example

This example shows a Drill query on a Streams data set, which was made accessible to Drill through the kafka storage plugin.

For this example, tables that contain Yelp stream topics reside in a directory named /YelpStream. The kafka storage plugin is configured with the `streams.consumer.default.stream` parameter pointing to the /YelpStream directory, as shown:

```
"streams.consumer.default.stream": "/YelpStream"
```

The USE command tells Drill to access data from only the kafka data source:

```
use kafka;
+-----+-----+
| ok | summary |
+-----+-----+
| true | Default schema changed to [kafka] |
+-----+-----+
```

The SHOW TABLES command lists the tables in the /YelpStream directory configured for the kafka data source:

```
show tables;
+-----+-----+
| TABLE_SCHEMA | TABLE_NAME |
+-----+-----+
| kafka | /YelpStream:UserTable |
| kafka | /YelpStream:ReviewTable |
| kafka | /YelpStream:BusinessTable |
+-----+-----+
```

The query selects all the data from the BusinessTable in the /YelpStream directory, limiting the results to one row data:

```
select * from `YelpStream:BusinessTable` limit 1;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| _id | attributes | business_id | categories | city | full_address | hours |
| latitude | longitude | name | neighborhoods | open | review_count | stars |
| state | type | kafkaTopic | kafkaPartitionId | kafkaMsgOffset |
kafkaMsgTimestamp | kafkaMsgKey |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+

Configuring the HBase Storage Plugin

As a Hadoop database, Apache HBase is a distributed, scalable, and big data store. Use and configure the HBase storage plugin to connect with Apache Drill.

Prerequisites

Before configuring the HBase storage plugin, make sure that you have:

- HBase up and running.
- ZooKeeper installed.
- Administrator privileges.

About this task

This task outlines how to configure the HBase storage plugin.

Procedure

1. Verify that HBase is running.
2. [Start the Drill Web UI](#).
3. Select the **Storage** tab.
4. Click **Update** to begin the configuration process.

The following shows a typical HBase configuration:

```
{
  "type": "hbase",
  "config": {
    "hbase.zookeeper.quorum": "10.10.100.62,10.10.10.52,10.10.10.53",
    "hbase.zookeeper.property.clientPort": "2181"
  },
  "size.calculator.enabled": false,
  "enabled": true
}
```

The following shows a secure cluster configuration:

```
{
  "type": "hbase",
  "config": {
    "hbase.zookeeper.quorum": "node1.cluster.com",
    "hbase.zookeeper.property.clientPort": "5181",
    "hbase.security.authentication": "MAPRSASL"
  },
  "size.calculator.enabled": false,
  "enabled": true
}
```

Start the Drill Web UI

The Drill Web UI is one of several client interfaces that you can use to access Drill.

Accessing the Drill Web UI

To open the Drill Web UI, launch a web browser, and go to one of the following URLs:

- If HTTPS support is disabled, use the default URL: `http://<IP address or host name>:8047`
- If HTTPS support is enabled, use this URL: `https://<IP address or host name>:8047`

If user authentication is *not* enabled, all the Drill Web UI controls appear to users and administrators, including Query, Profiles, Storage, Metrics, and Threads:

If user authentication is enabled, Drill prompts you for a user name and password:

If an administrator logs in, all the Drill Web UI controls appear, including Query, Profiles, Storage, Metrics, Threads, and Options. For administrators, the Profiles page contains the profiles of all queries executed

on a cluster. Only administrators can see and use the Storage tab to view, update, or add a new storage plugin configuration. Only administrators can see and use the Threads tab, which provides information about threads running in Drill.

If a non-administrative user logs in, the Drill Web UI controls are limited to Query, Metrics, and Profiles. The Profiles tab for a non-administrative user contains the profiles of all queries the user issued either through ODBC, JDBC, or the Drill Web UI.

More information

<https://drill.apache.org/docs/architecture-introduction/#drill-clients>

<https://drill.apache.org/docs/securing-drill/>

Start the Drill Shell (SQLLine)

SQLLine is a JDBC application packaged with Drill that serves as the Drill shell. When you issue queries from the SQLLine, the SQLLine client sends the queries to the connected Drillbit (Drill node).

You can connect to Drill through SQLLine directly or through a connection-property file. If want to avoid exposing credentials, connecting through the connection-property file is recommended.

A JDBC connection string supplies the connection information to a Drill node or ZooKeeper cluster. When connecting to a ZooKeeper cluster, ZooKeeper selects the Drillbit that SQLLine connects to.

JDBC Connection String

This is an example of a JDBC connection string that connects SQLLine to drillnode1:

```
jdbc:drill:drillbit=drillnode1:31010
```

The default port on any Drill node is 31010.

Starting SQLLine

You start SQLLine from the Drill installation directory, as shown in the following example where SQLLine connects directly to a Drill node named drillnode1:

```
/opt/mapr/drill/drill-<version>/bin/sqlline -u  
jdbc:drill:drillbit=drillnode1:31010
```

Connection Parameters

You can include SQLLine connection parameters in the connection string and run various shell commands, as described in [Configuring the Drill Shell](#).

In the following example, -u is the connection parameter for the JDBC connection string, -n is the parameter for the username, and -p is the parameter for the password:

```
/opt/mapr/drill/drill-<version>/bin/sqlline -u  
"jdbc:drill:drillbit=drillnode1:31010" -n mapr -p mapr
```

In the following example, the !connect shell command is used to hide the password when making an authenticated connection:

```
//From /opt/mapr/drill/drill-<version>/, run:  
  
bin/sqlline  
  
//The sqlline prompt appears. At the prompt, provide the connection string  
with the !connect property:  
  
sqlline> !connect jdbc:drill:drillbit=drillnode1:31010  
//The system prompts you for the username and password.  
Enter username for jdbc:drill:drillbit=drillnode1:31010: mapr  
Enter password for jdbc:drill:drillbit=drillnode1:31010: *****
```

NOTICE: In Drill 1.15, the SQLLine `!connect` command incorrectly requests a username and password when connecting to a secure cluster via MAPRSASL or KERBEROS authentication:

```
sqlline> !connect jdbc:drill:drillbit=drillnode1:31010;auth=MAPRSASL

//!connect usage: connect <url> <username> <password> [driver]
//Driver is optional. Driver is the Apache Drill driver class,
org.apache.drill.jdbc.Driver.
```

To workaroud this issue, provide your username when you connect and press Enter when prompted for the password:

```
sqlline> !connect jdbc:drill:drillbit=drillnode1:31010;auth=MAPRSASL
mapr
Enter password for jdbc:drill:drillbit=drillnode1:31010;auth=MAPRSASL:
```

Alternatively, you can use an empty quote in place of a username:

```
sqlline> !connect jdbc:drill:drillbit=drillnode1:31010;auth=MAPRSASL ""
```

Configuration Options

You can also include configuration options, such as schema and auth (if authentication is enabled):

```
/opt/mapr/drill/drill-<version>/bin/sqlline -u "jdbc:drill:drillbit
drillnode1:31010;schema=dfs;auth=MAPRSASL"
```

Schema

The schema is the name of a [storage plugin](#) configuration to use as the default for queries. If you indicate the schema in the connection string, you do not have to run the `USE <schema>;` query to switch to the schema you want to use. All queries run against the schema indicated in the JDBC connection string.

Authentication

If authentication is enabled (Plain, MAPRSASL, Kerberos), include the auth option in the connection string. If Drill is installed on a cluster secured by the default security, set `auth=MAPRSASL`. If using Plain authentication, include the username and password, as shown:

```
/opt/mapr/drill/drill-<version>/bin/
sqlline -u "jdbc:drill:drillbit
drillnode1:31010;schema=dfs;auth=MAPRS
ASL"
```

Connecting to a Specific Drill Node

Indicate which Drill node you want SQLLine to connect to in the JDBC connection string, using the following JDBC connection string format:

```
jdbc:drill:drillbit=<host>:<port>
```

Note that properties are case-sensitive. The host is the DNS or IP address of the server (Drill node). The default connection port is 31010.

Example

The following example shows you how to start SQLLine with a JDBC connection string that includes the username, password, and auth parameters to authenticate to the server with Plain authentication:

```
/opt/mapr/drill/drill-<version>/bin/sqlline -u
"jdbc:drill:drillbit=<ip-address>:<port>;auth=PLAIN" -n <username> -p
<password>
```

If you installed Drill on a cluster secured by default security, set the auth type to maprsasl:

```
/opt/mapr/drill/drill-<version>/bin/sqlline -u
"jdbc:drill:drillbit=<ip-address>:<port>;auth=MAPRSASL"
```

Connecting to ZooKeeper

When you include the ZooKeeper nodes in the JDBC connection string, ZooKeeper selects an available Drill node for SQLLine to connect to.

Indicate the ZooKeeper cluster you want SQLLine to connect to in the JDBC connection string, using the following JDBC connection string format:

```
jdbc:drill:zk=<zk-server-list>/drill/<clustername>
```

The `zk-server-list` is a comma-separated list of the ZooKeeper nodes in the cluster. The `clustername` is the unique name of the Drillbit cluster that you want to connect to.

You can locate the name of the Drillbit cluster in `/opt/mapr/drill/drill-<version>/conf/drill-distrib.conf`. The default name of the Drillbit cluster is `drillbits1`. The name is set by the `cluster-id` property. If you have multiple Drill clusters, you may want to override the Drillbit cluster name in `drill-override.conf`. However, first [back-up your storage plugin configurations](#), as they may reset to the defaults when you change the cluster name. Restart Drill after you edit `drill-override.conf`.

Example

The following example shows you how to configure the JDBC connection string to connect SQLLine to the ZooKeeper cluster:

```
/opt/mapr/drill/drill-<version>/bin/sqlline
jdbc:drill:zk=<node-ip>:<port>,<node-ip>:<port>,<node-ip>:<port>/drill/
drillbits1;auth=PLAIN -n <username> -p <password>
```

The default port for ZooKeeper nodes is 5181.

If you installed Drill on a secure cluster, set the auth type to MAPRSASL:

```
/opt/mapr/drill/drill-<version>/bin/sqlline
jdbc:drill:zk=<node-ip>:<port>,<node-ip>:<port>,<node-ip>:<port>/drill/
drillbits1;auth=MAPRSASL
```

Using a Connection-Property File with SQLLine

Make sure you restrict access to the connection-property file to specific users.

Create a connection-property file named `login.properties`, as shown:

```
url:<jdbc-connection-url>
user:<username>
password:<password>

//Example
cat login.properties
```

```
url:jdbc:drill:schema=dfs;drillbit=drill-lab-node01
user:drilluser
password:letsdrill
```

To connect to Drill, run SQLLine as shown:

```
sqlline <sqlline args> <path/to/login.properties file>
```

The following examples show you how you can use the connection-property file to connect to Drill:

Example 1: Connecting to Drill via the connection-property file

Run SQLLine from /opt/mapr/drill/drill-<version>/bin:

```
sqlline login.properties

//List the active connection:
0: jdbc:drill:schema=dfs> !list
1 active connection:
  #0  open
  jdbc:drill:schema=dfs;drillbit=drill-lab-node01

//Exit SQLLine:
0: jdbc:drill:schema=dfs>!q
```

Example 2: Submitting a query when connecting to Drill via the connection-property file

Run SQLLine from /opt/mapr/drill/drill-<version>/bin:

```
sqlline -q "SELECT version FROM sys.version" login.properties

//Run query:
0: jdbc:drill:schema=dfs> select
version from sys.version;
+-----+
| version |
+-----+
| 1.16.0  |
+-----+
1 row selected (0.295 seconds)
```

Example 3: Use the properties command to connect to Drill via the connection-property

Run SQLLine from /opt/mapr/drill/drill-<version>/bin:

```
sqlline

//At sqlline the prompt, run:
sqlline> !properties /home/drilluser/
login.properties
0: jdbc:drill:schema=dfs>
0: jdbc:drill:schema=dfs> !list
1 active connection:
  #0  open
  jdbc:drill:schema=dfs;drillbit=drill-lab-node01
0: jdbc:drill:schema=dfs>
```

Verify that Login Details are Secure

Run the following command to verify that login details are not exposed to other users:

```
ps -ef | grep sqlline

drilluser      18938 21924  99 14:14
pts/0        00:00:03 /opt/
jdk1.8.0_141/bin/
java -XX:MaxPermSize=512M -Djava.secur
ity.auth.login.config=/opt/mapr/conf/
mapr.login.conf \
-Dzookeeper.sasl.client=false -Dhadoop
.login=simple -Dlog.path=/opt/mapr/
drill/drill-1.10.0/logs/
sqlline.log -Dlog.query.path=/opt/
mapr/drill/drill-1.16.0/logs/
sqlline_queries.json \
-cp /opt/mapr/drill/drill-1.10.0/
conf:/opt/mapr/drill/drill-1.16.0/
jars/*:/opt/mapr/drill/drill-1.16.0/
jars/ext/*:/opt/mapr/drill/
drill-1.16.0/jars/3rdparty/*:/opt/
mapr/drill/drill-1.16.0/jars/classb/*
sqlline.SqlLine -d
org.apache.drill.jdbc.Driver --maxWidt
h=10000 --color=true login.properties
drilluser      20119 1691   0 14:14
pts/1        00:00:00 grep sqlline
```

Exit SQLLine

To exit SQLLine, run `!quit`.

Start|Stop the Drill Process

You can start|stop|restart the Drill process on one or more nodes using the Control System or the following command:

```
maprcli node services -name drill-bits -action start|restart|stop -nodes
<node host names separated by a space>
```

Use the host name if possible. Using host names instead of IP addresses is a best practice.

Related concepts

[Data Fabric Drill Drivers](#) on page 4836

HPE Data Fabric provides Drill ODBC and JDBC drivers that you can download and use to connect Drill to BI tools. The drivers are updated periodically to include support for new functionality in Drill.

[Drill JDBC Drivers](#) on page 4837

Download the Drill JDBC driver and use it on all platforms to connect BI tools, such as SquirrelL to Drill.

Hive to Drill Type Mapping

Using Drill you can read tables created in Hive that use data types in the [Hive-to-Drill type mapping table](#). Currently, the Apache Hive version used by Drill does not support the timestamp in Unix Epoch format. The workaround is to use the JDBC format for the timestamp, which Hive accepts and Drill uses, as shown in the [type mapping example](#).

For more information about connecting Drill to data sources, refer to [Connect to Data Sources](#) on the [Apache Drill documentation web site](#). For information about workspaces, refer to [Workspaces](#).

Securing Drill

An administrator can install Drill with the default security configuration or manually configure custom security for Drill.

Drill supports several security features that secure the communication paths between Drill clients (such as [ODBC/JDBC](#)) and Drillbits and also between Drillbits. The following sections briefly describe the security configuration options for Drill and provide links to additional information and instructions.

Default Security Configuration

Starting in Core 6.0 and Drill 1.11 (EEP 4.0), Drill is automatically secured when you install Drill on a cluster that was installed with the default security configuration. The default security configuration provides authentication, authorization, and encryption through the Data Fabric-SASL mechanism, except for HTTPS, which uses [SSL/TLS](#) with form-based authentication. See [Drill Default Security](#) and [SSL/TLS for Encryption](#) for more information. You may also want to reference the following topics:

- [Installing Drill](#), which describes some Drill installation security scenarios.
- [Data Fabric Drill Drivers](#) on page 4836, where you can access the JDBC and ODBC driver information and downloads required to connect to Drill when using the default security configuration.

NOTE: The default security configuration does not include Kerberos or Plain authentication; however, you can manually configure these security mechanisms in addition to the default security configuration.

Security Features Supported in a Custom Configuration

Drill supports several security features that an [administrator](#) can manually configure to secure the communication paths between the Drill client and Drillbit and also between Drillbits.

The following table lists the security features and mechanisms supported by Drill, as well as the communication paths secured by each mechanism:

NOTE: In the following table, Drill client refers to the Drill ODBC and JDBC clients. See [Drill Drivers](#) for ODBC and JDBC driver information.

Security Features	Supported Mechanisms	Communication Paths Secured
Authentication	MapR Security (Data Fabric-SASL/Tickets)	<ul style="list-style-type: none"> • Drill client to Drillbit • Drillbit to Drillbit • Drillbit to ZooKeeper <p> NOTE: The Drillbit creates znodes, for which ZooKeeper ACLs provide security. See Security Between ZooKeeper and Drillbits for more information.</p>
	Kerberos	<ul style="list-style-type: none"> • Drill client to Drillbit • Drillbit to Drillbit
	Plain (username and password)	<ul style="list-style-type: none"> • Drill client to Drillbit

Security Features	Supported Mechanisms	Communication Paths Secured
	Form-based	<ul style="list-style-type: none"> Web client/REST API to Drillbit  NOTE: You can configure SSL/TLS for encryption.
	SPNEGO for HTTP	<ul style="list-style-type: none"> Web client/REST API to Drillbit  NOTE: You can configure SSL/TLS for encryption.
Encryption	MapR Security (Data Fabric/Tickets)	<ul style="list-style-type: none"> Drill client to Drillbit Drillbit to Drillbit
	Kerberos	<ul style="list-style-type: none"> Drill client to Drillbit Drillbit to Drillbit
	SSL/TLS	<ul style="list-style-type: none"> Drill client to Drillbit Web client/REST API to Drillbit
Authorization	Based on filesystem permissions.	<ul style="list-style-type: none"> Drill client to Drillbit
Impersonation	User Impersonation	<ul style="list-style-type: none"> Drill client to Drillbit  NOTE: Drill supports user impersonation, inbound impersonation, and user impersonation with Hive authorization.
	Inbound impersonation	<ul style="list-style-type: none"> Drill client to Drillbit  NOTE: Supports setting inbound impersonation policies, which are used to verify whether the user (set as the DelegationUID parameter passed in the client connection URL) can be impersonated by the connection user or not.

Views and File ACEs

In addition to the listed security features, you can [create views](#) on data to limit access to the data. You can also create [file ACEs](#) on the view definition files to protect the views.

Related concepts

[Data Fabric Drill Drivers](#) on page 4836

HPE Data Fabric provides Drill ODBC and JDBC drivers that you can download and use to connect Drill to BI tools. The drivers are updated periodically to include support for new functionality in Drill.

[Start the Drill Shell \(SQLLine\)](#) on page 4771

SQLLine is a JDBC application packaged with Drill that serves as the Drill shell. When you issue queries from the SQLLine, the SQLLine client sends the queries to the connected Drillbit (Drill node).

[Connection URLs for Kerberos using JDBC Drivers to connect via SQLLine](#) on page 4805

You can use client-side connection URL parameters for Kerberos authentication in multiple combinations to authenticate a client with Drill.

[Connection URL for Plain Authentication using the Apache JDBC Driver to connect via SQLLine](#) on page 4812

When Plain authentication is enabled, each user that accesses the Drillbit process through a client, must provide username and password credentials for access.

[SSL/TLS for Encryption](#) on page 4813

You can enable SSL for Drill in a secure cluster. SSL (Secure Sockets Layer), more recently called TLS, is a security mechanism that encrypts data passed between the Drill client and Drillbit (server). SSL also provides one-way authentication through which the Drill client verifies the identity of the Drillbit.

[Configuring Drill Web UI and Web API Security](#) on page 4824

The Drill web client and web API communicate with web browsers or web tools, like curl, through the HTTP or HTTPS. Drill uses HTTP by default.

[SPNEGO for HTTP Authentication](#) on page 4831

Drill 1.13 and later supports the Simple and Protected GSS-API Negotiation mechanism (SPNEGO) to extend the Kerberos-based single sign-on authentication mechanism to HTTP. An administrator configures the web server (Drillbit) to use SPNEGO for authentication. Depending on the system, either the administrator or the user configures the client (web browser or web client tool) to use SPNEGO for authentication.

Roles and Privileges

Drill has USER and ADMIN roles. Each role can perform different functions in Drill.

Access in the Drill Web UI differs between users and administrators. Certain pages are exposed based on privilege. For example, only administrators can see the Storage tab and edit a storage plugin configuration.

The following sections describe a few additional differences between a user and an administrator in Drill.

USER Role

The following list notes the functions that a user can perform in Drill:

- Users can run queries on data to which they have access.
- Users can view and cancel their own queries in the Profiles tab of the Drill Web UI.
- Users can create views on data to provide granular access to that data.

NOTE: Each data source manages the read/write permissions.

ADMIN Role

When authentication is enabled, only Drill users assigned the administrator (ADMIN) role can perform the following tasks:

- Change system-level options by issuing the ALTER SYSTEM command or through the options tab in the Drill Web UI.
- Update a storage plugin configuration through the REST API or Drill Web UI.
- View the profiles of all queries run by all users.
- Cancel running queries that were launched by any user in the cluster.
- Shut down the Drillbit in the Drill Web UI.

Configuring USER and ADMIN Roles

You can define administrative users through the `security.admin.user_groups` and `security.admin.users` options.

The default value for `admin.users` is the `drill_process_user`. The default value for `admin.user_groups` is `drill_process_user_groups`. These options accept a comma-separated list of users or user groups.

To edit these options, use the SET command, as shown in the following examples:

```
ALTER SYSTEM SET `security.admin.user_groups` = 'drill,
%drill_process_user_groups%';
ALTER SYSTEM SET `security.admin.users` = 'user1, %drill_process_user%';
ALTER SYSTEM SET `security.admin.users` = 'user1, user2';
```

Drill Default Security

The default security configuration uses MapR-SASL (tickets) for authentication, authorization, and encryption to automatically secure the cluster and ecosystem components when you install them manually or using the Installer.

The default security configuration automatically secures all Drill communication paths with the following exceptions:

- The path between the web client and web server (W) uses [SSL/TLS](#) with form-based authentication.
- The path between the ODBC/JDBC client and ZooKeeper (Zn, Zo) is unsecure.

The following diagram shows the secured communication paths:

The following table describes the security support for each communication path in the diagram, along with the components involved in the communication:

Type of Security Supported	Communication Path	Component Communication
Authentication and encryption using MapR-SASL (tickets)	C	ODBC client/C++ API to Drillbits
	J	JDBC client/Java API to Drillbits
	D1, D2, Dn	Drillbit to Drillbit
	M	Drillbit to HPE Data Fabric Database/file system

	H	Drillbit to Hive  NOTE: The Hive storage plugin is not secured by default and requires that you manually modify the configuration to enable security. See Configuring the Hive Storage Plugin on page 4764.
Plain authentication with SSL encryption (HTTPS enabled)	W	Web client/Web API to Web server  NOTE: The HTTPS channel (Web client) uses Plain authentication to authenticate a Web client with SSL/TLS for encryption. This is configured by default in a secure 6.x cluster with Drill 1.11 or later installed. Plain authentication does not support encryption. You must enable SSL to encrypt the communication channels when using Plain authentication. See Configuring Drill Web UI and Web API Security on page 4824.
Authentication with security (no encryption)	Zj	Drillbit to ZooKeeper  NOTE: The Drillbit creates znodes, for which ZooKeeper ACLs provide security. See Security Between ZooKeeper and Drillbits on page 4823 for more information.
No security support	Zo, Zn	ODBC/JDBC client to ZooKeeper  NOTE: Only znodes created for Drillbit endpoints in Zookeeper are readable by the client. All other znodes (not required by the client) are secured using ZooKeeper ACLs , and are only readable by Drillbits.

Note the following information:

- [Kerberos](#) and [Plain authentication](#) are not enabled or configured as part of the default security configuration. However, you can manually configure these security mechanisms in addition to the defaults. If you enable Plain authentication, you must use [SSL/TLS](#) for encryption.
- Drill clients running Drill 1.10 and earlier do not support encryption and cannot connect to Drillbits installed with the default security configuration.

Connecting Drill

See [Data Fabric Drill Drivers](#) on page 4836. Alternatively, you can use [SQLLine](#), the [Drill shell](#), as shown:

Additional Notes

Performance

The default security configuration enables encryption for all network channels, which can affect Drill performance. If performance is your highest priority, install Data Fabric and Drill without security enabled and have your security expert manually configure cluster security. Alternatively, you can install Data Fabric and Drill with security enabled, and then disable individual Drill security settings. For example, you can edit the `drill-override.conf` file and disable encryption, leaving authentication enabled.

NOTE: Manually configuring security settings when default security is enabled is not recommended.

Drill Configuration Files

The default security configuration introduces new Drill configuration files. In addition to `drill-override.conf`, `distrib-env.sh`, and `drill-env.sh`, Drill includes a `drill-distrib.conf` file. See [Drill Configuration Files](#) on page 4859 for more information. Note that modifying drill distribution-specific files is highly discouraged. To customize any Drill configuration, use `drill-override.conf` and `drill-env.sh`.

HBase

As of Core 6.0 and Drill 1.11, HBase is no longer supported; therefore, the communication path between Drill and HBase is also not supported.

User Impersonation

Impersonation allows a service to act on behalf of a client while performing the action requested by the client. By default, user impersonation is disabled in Drill. You can configure user impersonation in the `/opt/mapr/drill/drill-<version>/drill-override.conf` file.

When you enable impersonation, Drill executes all the client requests as the user logged in to the client. Drill passes the user credentials to the file system, and the file system checks to see if the user has permission to access the data. When you enable authentication, Drill uses the pluggable authentication module (PAM) to authenticate a user's identity before the user can access the Drillbit process.

If impersonation is disabled, Drill executes all of the client requests against the file system as the user that started the Drillbit service on the node. This is typically a privileged user. The file system verifies that the system user has permission to access the data.

User Impersonation Example

When impersonation is disabled and user Bob issues a query through the SQLLine client, SQLLine passes the query to the connecting Drillbit. The Drillbit executes the query as the system user that started the Drill process on the node. For the purpose of this example, we will assume that the system user has full access to the file system. Drill executes the query and returns the results back to the client.

When impersonation is enabled and user Bob issues a query through the SQLLine client, the Drillbit uses Bob's credentials to access data in the file system. The file system checks to see if Bob has permission to access the data. If Bob has permission, Drill returns the query results to the client. If Bob does not have permission, Drill returns an error.

Impersonation Support

Drill supports impersonation with the following clients, storage plugins, and types of queries:

- **Clients**
 - ODBC

- JDBC
- REST API
- Drill Web UI
- **Storage plugins**
 - file system
 - HPE Data Fabric Database
 - Hive
- **Types of queries**

NOTE: When you enable impersonation, the setting applies to queries on data and metadata. For example, if you issue the `SHOW SCHEMAS` command, Drill impersonates the user logged into the client to access the requested metadata. If you issue a `SELECT` query on a workspace, Drill impersonates the user logged in to the client to access the requested data.

Drill applies impersonation to queries issued using the following commands:

- `SHOW SCHEMAS`
- `SHOW DATABASES`
- `SHOW TABLES`
- `CTAS`
- `SELECT`
- `CREATE VIEW`
- `DROP VIEW`
- `SHOW FILES.`

NOTE: To successfully run the `CTAS` and `CREATE VIEW` commands, a user must have write permissions on the directory where the table or view will exist. Running these commands creates artifacts on the file system.

Impersonation and Views

You can use views with impersonation to provide granular access to data and protect sensitive information.

When you create a view, Drill stores the view definition in a file and suffixes the file with `view.drill`. For example, if you create a view named `myview`, Drill creates a view file named `myview.view.drill` and saves it in the current workspace or the workspace specified, such as `dfs.views.myview`. See [CREATE VIEW](#).

You can create a view and grant read permissions on the view to give other users access to the data that the view references. When a user queries a view on which s/he has read access, Drill impersonates the view owner to access the underlying data. If the user tries to query the data directly (instead of using the view), Drill returns a permission denied error. A user with read access to a view can create new views from the originating view to further restrict access on data.

View Permissions

A user must have write permission on a directory or workspace to create a view, as well as read access on the table(s) and/or view(s) that the view references. When a user creates a view, permission on the view is

set to owner by default. Users can query an existing view or create new views from the view if they have read permissions on the view file and the directory or workspace where the view file is stored.

When users query a view, Drill accesses the underlying data as the user that created the view. If a user does not have permission to access a view, the query fails and Drill returns an error. Only the view owner or a superuser can modify view permissions to change them from owner to group or world.

The view owner or a superuser can modify permissions on the view file directly or they can set view permissions at the system or session level prior to creating any views. Any user that alters view permissions must have write access on the directory or workspace in which they are working.

Modifying Permissions on a View File

Only a view owner or a super user can modify permissions on a view file to change them from owner to group or world readable. Before you grant permission to users to access a view, verify that they have access to the directory or workspace in which the view file is stored.

Use the `chmod` and `chown` commands with the appropriate octal code to change permissions on a view file:

```
hadoop fs -chmod <octal code> <file_name>
hadoop fs -chown <user>:<group> <file_name>
//hadoop fs -chmod 750 employees.view.drill
```

Modifying SYSTEM|SESSION Level View Permissions

Use the `ALTER SESSION|SYSTEM` command with the `new_view_default_permissions` parameter and the appropriate octal code to set view permissions at the system or session level prior to creating a view.

```
ALTER SESSION SET `new_view_default_permissions` = '<octal_code>';
ALTER SYSTEM SET `new_view_default_permissions` = '<octal_code>';
//ALTER SESSION SET `new_view_default_permissions` = '777';
```

After you set this parameter, Drill applies the same permissions on each view created during the session or across all sessions if set at the system level.

Chained Impersonation

You can configure Drill to allow chained impersonation on views when you enable impersonation in the `drill-override.conf` file. Chained impersonation controls the number of identity transitions that Drill can make when a user queries a view. Each identity transition is equal to one hop.

An administrator can set the maximum number of hops for impersonation to limit the number of times that Drill can impersonate a different user when other users query a view. The default maximum number of hops is set at 3. When the maximum number of hops is set to 0, Drill does not allow impersonation chaining, and a user can only read data for which they have direct permission to access. An administrator may set the chain length to 0 to protect highly sensitive data.

The following diagram depicts a scenario where the maximum hop number is set to 3, and Drill must impersonate three users to access data when Chad queries a view that Jane created:

In the previous example, Joe created V2 from the view that user Frank created. In the following example, Joe created V3 by joining a view that Frank created with a view that Bob created.

Although V3 was created by joining two different views, the number of hops remains at 3 because Drill does not read the views at the same time. Drill reads V2 first and then reads V1.

In the next example, Bob queries V4 which was created by Frank. Frank's view was created from several underlying views. Charlie created V2 by joining Jane's V1 with Kris's V1.2. Kris's V1.2 was created from Amy's V1.1, increasing the complexity of the chaining. Assuming that the hop limit is set at 4, this scenario exceeds the limit.

When Bob queries Franks's view, Drill returns an error stating that the query cannot complete because the number of hops required to access the data exceeds the maximum hop setting of 4.

If users encounter this error, the administrator can increase the maximum hop setting to accommodate users running queries on views.

Configuring Impersonation and Chaining

Impersonation allows a service to act on behalf of a client while performing the action requested by the client. Chaining is a system-wide setting that applies to all views. Currently, Drill does not provide an option to allow different chain lengths for different views.

Complete the following steps on each Drillbit node to enable user impersonation, and set the maximum number of chained user hops that Drill allows:

1. Navigate to `<drill_installation_directory>/conf/` and edit `drill-override.conf`.

- Under `drill.exec`, add the following:

```
drill.exec.impersonation: {
    enabled: true,
    max_chained_user_hops: 3
}
```

Alternatively, you can nest impersonation within the `drill.exec` block, as shown in the following example:

```
drill.exec: {
    cluster-id: "cluster_name",
    zk.connect:
    "<hostname>:<port>,<hostname>:<port>,<hostname>:<port>",
    sys.store.provider.zk.blobroot: "hdfs://",
    impersonation: {
        enabled: true,
        max_chained_user_hops: 3
    }
}
```

- Set the maximum number of chained user hops.
- In `<drill_installation_directory>/conf/drill-env.sh`, add one of the following lines:
 - If the underlying filesystem has security enabled, add the following line: `export MAPR_TICKETFILE_LOCATION=/opt/mapr/conf/mapruser.ticket`
 - If the underlying filesystem is not secure, add the following line: `export MAPR_IMPERSONATION_ENABLED=true`
- Restart the Drillbit process on each Drill node.

```
maprcli node services -name drill-bits -action restart -nodes
<node-hostnames-separated-by-a-space> -f
```

Example: Impersonation and Chaining

This example demonstrates how to use impersonation and chaining to limit access to data. Impersonation allows a service to act on behalf of a client while performing the action requested by the client. Chaining controls the number of identity transitions that Drill can make when a user queries a view.

NOTE: The number of identity transitions is controlled by the `max_chained_user_hops` option in the `drill-override.conf` file. See [Chained Impersonation](#) and [Configuring Impersonation and Chaining](#) for more information.

Frank is a senior HR manager at a company. Frank has access to all of the employee data because he is a member of the hr group. Frank created a table named “employees” in his home directory to store the employee data he uses. Only Frank has access to this table.

```
drwx----- frank:hr /user/frank/employees
```

Each record in the employees table consists of the following information: `emp_id`, `emp_name`, `emp_ssn`, `emp_salary`, `emp_addr`, `emp_phone`, `emp_mgr`

Frank needs to share a subset of this information with Joe who is an HR manager reporting to Frank. To share the employee data, Frank creates a view called `emp_mgr_view` that accesses a subset of the data. The `emp_mgr_view` filters out sensitive employee information, such as the employee social security

numbers, and only shows data for the employees that report directly to Joe. Frank and Joe both belong to the mgr group. Managers have read permission on Frank's directory.

```
rwxr----- frank:mgr /user/frank/emp_mgr_view.view.drill
```

The emp_mgr_view.view.drill file contains the following view definition:

```
(view definition: SELECT emp_id, emp_name, emp_salary, emp_addr, emp_phone
FROM `/user/frank/employee` WHERE emp_mgr = 'Joe')
```

When Joe issues `SELECT * FROM emp_mgr_view`, Drill impersonates Frank when accessing the employee data, and the query returns the data that Joe has permission to see based on the view definition. The query results do not include any sensitive data because the view protects that information. If Joe tries to query the employees table directly, Drill returns an error or null values.

Because Joe has read permissions on the emp_mgr_view, he can create new views from it to give other users access to the employee data even though he does not own the employees table and cannot access the employees table directly.

Joe needs to share employee contact data with his direct reports, so he creates a special view called emp_team_view to share the employee contact information with his team. Joe creates the view and writes it to his home directory. Joe and his reports belong to a group named joeteam. The joeteam group has read permissions on Joe's home directory so they can query the view and create new views from it.

```
rwxr----- joe:joeteam /user/joe/emp_team_view.view.drill
```

The emp_team_view.view.drill file contains the following view definition:

```
(view definition: SELECT emp_id, emp_name, emp_phone FROM `/user/frank/
emp_mgr_view.drill`);
```

When anyone on Joe's team issues `SELECT * FROM emp_team_view`, Drill impersonates Joe to access the emp_team_view and then impersonates Frank to access the emp_mgr_view and the employee data. Drill returns the data that Joe's team has can see based on the view definition. If anyone on Joe's team tries to query the emp_mgr_view or employees table directly, Drill returns an error or null values.

Because Joe's team has read permissions on the emp_team_view, they can create new views from it and write the views to any directory for which they have write access. Creating views can continue until Drill reaches the maximum number of impersonation hops (chained impersonation).

User Impersonation with Hive

You can configure Drill impersonation with Hive impersonation to authorize access to metadata in the Hive metastore repository and data in the Hive warehouse. [Drill impersonation](#) works with Hive when Hive has impersonation enabled and optionally, storage based or SQL standard based authorization enabled. Drill impersonation can also work with Hive when the Hive metastore has Kerberos enabled on a secure cluster. Currently, Drill does not support Hive configured with Sentry authorization.

Storage Based Authorization

Hive storage based authorization is a remote metastore server security feature that uses the underlying file system permissions to determine permissions on databases, tables, and partitions. The permissions a user or group has on directories in the file system determines access to data. Because the file system controls access at the directory and file level, storage based authorization cannot control access to data at the column or view level.

You manage user and group privileges through permissions and access controls in the distributed file system. DDL statements that manage permissions, such as GRANT and REVOKE, do not have any effect on permissions in the storage based authorization model.

For more information, see [Storage Based Authorization in the Metastore Server](#).

SQL Standard Based Authorization

The SQL standard based authorization model can control which users have access to columns, rows, and views. SQL standard based authorization is configured in HiverServer2 and enforced during query processing. Users with the appropriate permissions can issue the GRANT and REVOKE statements to manage privileges from Hive.

For more information, see [SQL Standard Based Hive Authorization](#).

Prerequisites

To configure user impersonation with Hive, the system must meet the following requirements:

- Core version 4.1 or later
- Drill installed with Drillbits running as the mapr user
- Supported version of Hive installed with the following:
 - [User impersonation](#) enabled
 - Configured Hive remote metastore repository
 - (Optional) [SQL standard based authorization](#) or [storage based authorization](#) configured

NOTE: See [Ecosystem Pack Components and OS Support](#) on page 7672 for supported versions of Hive.

Configuration

Complete the steps listed in [Configuring User Impersonation with Hive](#).

Configuring User Impersonation with Hive

Complete the following steps on a secure or insecure cluster to configure user impersonation with Hive:

Step 1: Modify drill-env.sh

Modify <DRILL_HOME>/conf/drill-env.sh to include the required environment variables on each Drill node.

Insecure Cluster

On an insecure cluster, include the following environment variable:

```
export MAPR_IMPERSONATION_ENABLED=true
```

Secure Cluster

On a secure cluster, include the following environment variables:

```
export
DRILL_JAVA_OPTS="$DRILL_JAVA_OPTS -Djava.security.auth.login.config=/opt/mapr/conf/mapr.login.conf -Dzookeeper.sasl.client=true"
export
DRILL_JAVA_OPTS="$DRILL_JAVA_OPTS -Dmapr_sec_enabled=true -Dhadoop.login=maprsasl_keytab -Dzookeeper.saslprovider=com.mapr.security.maprsasl.MaprSaslProvider -Dmapr.library.flatclass"
```

```
export MAPR_TICKETFILE_LOCATION=/opt/
mapr/conf/mapruserticket
```

Step 2: Modify drill-override.conf

For secure and insecure clusters, modify <DRILL_HOME>/conf/drill-override.conf on each Drill node to enable impersonation in Drill, and set the [maximum number of chained user hops](#) that Drill allows.

Add the following configuration properties to the drill.exec block in drill-override.conf:

```
drill.exec: {
  cluster-id: "<drill_cluster_name>",
  zk.connect: "<hostname>:5181,<hostname>:5181,<hostname>:5181"
  impersonation: {
    enabled: true,
    max_chained_user_hops: 3
  }
}
```

Step 3: Modify the Hive Storage Plugin in Drill

Modify the Hive storage plugin configuration in the Drill Web UI based on the authorization and security scenario for the cluster. You can only access the Drill Web UI for a running Drillbit.

Complete the following steps to modify the Hive storage plugin configuration:

1. Navigate to `http://<drillbit_hostname>:8047`, and select the **Storage** tab.
2. Click **Update** next to the hive option.
3. In the configuration window, add the required properties based on the authorization type and security scenario:

Storage Based Authorization or No Authorization Enabled

For a *insecure cluster*, add the following properties to the configuration:

```
{
  type:"hive",
  enabled: true,
  configProps : {

    "hive.metastore.uris" : "thrift://
    <metastore_hostname>:9083",
    "fs.default.name" : "maprfs:///",
    "hive.metastore.sasl.enabled" :
    "false",
    "hive.server2.enable.doAs" :
    "true",

    "hive.metastore.execute.setugi" :
    "true"
  }
}
```

For a *secure cluster*, add the following properties to the configuration:

```
{
  "type": "hive",
  "enabled": true,
```

```
"configProps": {
  "hive.metastore.uris": "thrift://
<metastore_hostname>:9083",
  "fs.default.name": "maprfs:///",
  "hive.server2.enable.doAs": "true"
}
```

Add the following additional properties if the Hive metastore is configured with Kerberos in a secure cluster; include a comma after each line except for the last:

```
"hive.metastore.kerberos.principal":
"hive/<metastore_thrift_server>"
"hive.metastore.sasl.enabled":
"true"
```

SQL Standard Based Authorization

For an *insecure cluster*, add the following properties to the configuration:

```
{
  type:"hive",
  enabled: true,
  configProps : {
    "hive.metastore.uris" :
    "thrift://
    <metastore_hostname>:9083",
    "fs.default.name" : "maprfs:///",

    "hive.security.authorization.enabled
    " : "true",

    "hive.security.authenticator.manager
    " :
    "org.apache.hadoop.hive.ql.security.
    SessionStateUserAuthenticator",

    "hive.security.authorization.manager
    " :
    "org.apache.hadoop.hive.ql.security.
    authorization.plugin.sqlstd.SQLStdHi
    veAuthorizerFactory",
    "hive.metastore.sasl.enabled" :
    "false",
    "hive.server2.enable.doAs" :
    "false",

    "hive.metastore.execute.setugi" :
    "false"
  }
}
```

For a *secure cluster*, add the following properties to the configuration:

```
{
  "type": "hive",
  "enabled": true,
  "configProps": {
```

```

    "hive.metastore.uris": " thrift://
<metastore_hostname>:9083",
    "fs.default.name": "maprfs:///",

    "hive.security.authorization.enabled
": "true",

    "hive.security.authenticator.manager
":
    "org.apache.hadoop.hive.ql.security.
SessionStateUserAuthenticator",

    "hive.security.authorization.manager
":
    "org.apache.hadoop.hive.ql.security.
authorization.plugin.sqlstd.SQLStdHi
veAuthorizerFactory",
    "hive.server2.enable.doAs":
    "false",
    "hive.metastore.execute.setugi":
    "true"
  }
}

```

Add the following additional properties if the Hive metastore is configured with Kerberos in a secure cluster; include a comma after each line except for the last:

```

    "hive.metastore.kerberos.principal":
    "hive/<metastore_thrift_server>"
    "hive.metastore.sasl.enabled":
    "true"

```

Step 4: Restart Warden

Run the following command on all nodes to restart the Warden service:

```
service mapr-warden restart
```

If you have `clush` installed, you can run the following command to restart Warden on all nodes at once:

```
clush -a "service mapr-warden restart"
```

Inbound Impersonation

An administrator can define inbound impersonation policies to impersonate the end user.

Drill supports user impersonation where queries run as the user that created a connection. However, this user is not necessarily the end user who submits the queries. For example, in a classic three-tier architecture, the end user interacts with Tableau Desktop, which communicates with a Tableau Server, which in turn communicates with a Drill cluster. In this scenario, a proxy user creates a connection, and the queries are submitted to Drill by the proxy user on behalf of the end user, and not by the end user directly. In this particular case, the query needs run run as the end user.

The proxy user must be authorized to submit queries on behalf of the specified end user. Otherwise, any user can impersonate another user. The query runs as the end user, and data authorization is based on this user's access permissions. Note that without authentication enabled in both communication channels, a user can impersonate any other user.

Drill trusts proxy users to provide the correct end user identity information. Drill does not authenticate the end user. The proxy user (application) is responsible for end user authentication, which is usually enabled.

The following diagram shows how identity is propagated through various layers (with authentication enabled). The flow on the left is Drill with user impersonation enabled. The flow on the right is Drill with user impersonation and inbound impersonation enabled. `t: euser` is a property on the connection (`u` is username, `pis` password, `t` is `impersonation_target`).

The following topic provides instructions for configuring inbound impersonation:

Configuring Inbound Impersonation

Administrators can configure inbound impersonation in the `drill-override.conf` file.

Complete the following steps to enable inbound impersonation:

1. If user impersonation is not enabled, you must enable it before configuring inbound impersonation. To enable user impersonation, edit `/opt/mapr/drill/drill-<version>/drill-override.conf` and set the option to `true`, as shown:

```
{
    drill.exec.impersonation.enabled: true,
    ...
}
```

2. Define inbound impersonation policies. For example, the following `ALTER SYSTEM` statement authorizes:

- `puser1` to impersonate any user (use `*` as a wildcard character)
- `puser2` to impersonate `euser1` and all users in `egroup2`
- all users in `pgroup3` to impersonate all users in `egroup3`

```
ALTER SYSTEM SET `exec.impersonation.inbound_policies`='[
  { proxy_principals : { users: ["puser1"] },
    target_principals: { users: ["*"] } },
  { proxy_principals : { users: ["puser2"] },
    target_principals: { users: ["euser1"], groups : ["egroup2"] } },
  { proxy_principals : { groups: ["pgroup3"] },
    target_principals: { groups: ["egroup3"] } } ]';
```

Policy format:

```
{ proxy_principals : { users : ["...", "..."], groups : ["...", "..."] },
  target_principals: { users : ["...", "..."], groups : ["...", "..."] } }
```

3. Ensure that the proxy user (application) passes the username of the impersonation target user to Drill when creating a connection through the `impersonation_target` connection property. For example, through `sqlline`:

```
bin/sqlline -u
"jdbc:drill:schema=dfs;zk=myclusterzk;impersonation_target=euser1" -n
puser1 -p ppass1
```

NOTE: In this example, `puser1` is the user submitting the queries. This user is authenticated. Since this user is authorized to impersonate any user, queries through the established connection are run as `euser1`.

More information

<https://drill.apache.org/docs/configuration-options-introduction/#system-options>

Default Security (Tickets)

Drill supports authentication and encryption through the Default (tickets) security mechanism. Authentication is the process of establishing confidence of authenticity. Encryption is the process of converting information or data from plain text into ciphertext to prevent unauthorized access. An administrator can manually configure Drill to use Default Security. When Default Security is enabled, all Drill clients, such as JDBC and ODBC, must connect to Drillbits through Default Security.

The Default Security mechanism secures the communication path between the Drill client, such as JDBC/ODBC and Drillbit, Drillbit and ZooKeeper, and also between Drillbits.

NOTE: The Drill web communication path (web client to web server) does not support Default Security-based authentication and encryption.

NOTE: The Apache JDBC driver packaged with Drill does not support Default Security.

Configuration parameters in the Drill startup configuration file, `/opt/mapr/drill/drill-<version>/conf/drill-override.conf`, enable or disable authentication and encryption.

Prerequisites

- Ensure that your cluster is secure. To manually configure secure clusters with Default Security, see [Enable Wire-Level Security](#).
- When you configure Drill to use encryption, authentication must also be configured and enabled with the encryption-specific configurations.
- For encryption and authentication to work together, the Drill client and Drillbits must all run Drill 1.11 or later. Drill clients running earlier versions of Drill cannot connect to Drillbits when encryption is enabled.
- The client-side should have created a user mapr ticket for the authenticating user. See [maprlogin](#) for more information.

Post-requisite

You must restart the Drillbit process on each node after you enable security and/or modify the configuration options, as shown:

```
$ maprcli node services -name drill-bits -action restart -nodes <node host
names separated by a space>
```

Download and configure the JDBC or ODBC Drill drivers. See [Drill Drivers](#) for more information.

The following topics provide configuration information to enable authentication and encryption in Drill:

Configuring Authentication

An administrator can enable Default Security as the only authentication mechanism, or in addition to other mechanisms, such as Kerberos and Plain authentication in `drill-override.conf`.

NOTE: When Drill is installed on the HPE Data Fabric, Drill distribution defaults are stored in the `drill-distrib.conf` file. To override the defaults, you must explicitly disable them in the `drill-override.conf` file.

The following sections provide configuration examples for several configuration scenarios:

NOTE: For client-side configuration, see [Drill Drivers](#).

Example 1: Drill Client to Drillbit Authentication using Default Security Only

```
drill.exec:{
    security: {
        user.auth.enabled: true,
        auth.mechanisms : ["MAPRSASL"]
    }
}
```

NOTE: Drill executes all queries as a service or process user when impersonation is disabled.

Example 2: Drill Client to Drillbit Authentication with User Impersonation using Default

```
drill.exec:{
    security: {
        user.auth.enabled: true,
        auth.mechanisms : ["MAPRSASL"],
    }
    impersonation: {
        enabled: true,
        max_chained_user_hops: 3
    }
}
```

NOTE: Drill executes all queries as the authenticated (ticket) user when impersonation is enabled. The client to Drillbit communication path will not be encrypted.

Example 3: Drill Client to Drillbit using Multiple Authentication Mechanisms

```
drill.exec:{
    security: {
        user.auth.enabled: true,
        user.auth.impl: "pam4j",
        security.user.auth.packages +=
"org.apache.drill.exec.rpc.user.security",
        user.auth.pam_profiles: ["sudo", "login",
"mapr-admin"],
```

```

        auth.mechanisms : ["MAPRSASL", "KERBEROS", "PLAIN"],
        auth.principal : "mapr/_host@REALM.COM",
        auth.keytab : "/opt/mapr/conf/mapr.keytab"
    },
    impersonation: {
        enabled: true,
        max_chained_user_hops: 3
    }
}

```

Example 4: Drillbit to Drillbit Authentication using Default Security

```

drill.exec:{
    security: {
        auth.mechanisms : ["MAPRSASL"],
        bit.auth.enabled : true
        bit.auth.mechanism : "MAPRSASL"
    }
}

```

Example 5: Drill Client to Drillbit and Drillbit to Drillbit Authentication using Default Security

```

drill.exec {
    security: {
        user.auth.enabled: true,
        auth.mechanisms : ["MAPRSASL"],
        bit.auth.enabled : true,
        bit.auth.mechanism : "MAPRSASL"
    },
    impersonation: {
        enabled: true,
        max_chained_user_hops: 3
    }
}

```

Configuring Encryption

An administrator can enable encryption with Default Security (tickets).

NOTE: When the `sasl_encrypt` (for JDBC) or `EnforceSaslEncrypt` (for ODBC) connection parameter is set to "true" or 1, the Drill client only accepts encrypted connections. If the client tries connecting to a Drillbit with encryption disabled, the connection fails.

NOTE: For client-side configuration, see [Drill Drivers](#).

Set the encryption options to "true" in `/opt/mapr/drill/drill-<version>/conf/drill-override.conf`.

The following table lists the encryption configuration options with their descriptions and default values:

NOTE: If you installed Drill on a cluster that was installed with the default security configuration, the following options are set to "true" by default.

Option	Description	Default
<code>drill.exec.security.user.encryption.sasl.enabled</code>	Determines if encryption on the server is enabled for negotiating privacy with the Drill client.	false

drill.exec.security.bit.encryption.sasl.enabled	Determines if the server is enabled for negotiating privacy with another Drillbit.	false
---	--	-------

The following sections provide configuration examples for Drill client to Drillbit encryption and Drillbit to Drillbit encryption.

Example 1: Drill Client to Drillbit Connection with Default Security Authentication and Encryption

In the following server configuration, the Drill client connection to the Drillbit is encrypted using the Default Security mechanism when the client is running with encryption support.

NOTE: Drill clients running Drill 1.10 and earlier cannot connect to the Drillbit through Default Security with encryption enabled.

```
drill.exec {
  security: {
    user.auth.enabled: true,
    auth.mechanisms : ["MAPRSASL"]
    user.encryption.sasl.enabled : true
  }
}
```

NOTE: Drill executes all queries as a service or process user when impersonation is disabled.

Example 2: Drillbit to Drillbit Connection with Default Security Authentication and Encryption

The following configuration authenticates and encrypts the path between Drillbits using the Default Security mechanism.

```
drill.exec {
  security: {
    auth.mechanisms : ["MAPRSASL"],
    bit.auth.enabled : true
    bit.auth.mechanisms : "MAPRSASL"
    bit.encryption.sasl.enabled : true
  }
}
```

Example 3: Drill Client to Drillbit and Drillbit to Drillbit Connection with Default Security Authentication and Encryption

The following configuration authenticates and encrypts the path between the Drill client and Drillbit, and between Drillbits using the Default Security mechanism.

```
drill.exec {
  security: {
    user.auth.enabled: true,
    auth.mechanisms : ["MAPRSASL"],
    user.encryption.sasl.enabled : true

    bit.auth.enabled : true
    bit.auth.mechanism : "MAPRSASL"
    bit.encryption.sasl.enabled : true
  }
}
```

NOTE: Drill executes all queries as a service or process user when impersonation is disabled.

Example 4: Drill Client to Drillbit and Drillbit to Drillbit Connection with Default Security Authentication and Encryption and Impersonation Enabled

The following configuration authenticates and encrypts the path between the Drill client and Drillbit, and between Drillbits using the Default Security mechanism.

```
drill.exec {
  security: {
    user.auth.enabled: true,
    auth.mechanisms : ["MAPRSASL"],
    user.encryption.sasl.enabled : true

    bit.auth.enabled : true
    bit.auth.mechanism : "MAPRSASL"
    bit.encryption.sasl.enabled : true
  },
  impersonation: {
    enabled: true,
    max_chained_user_hops: 3
  }
}
```

NOTE: Drill executes all queries as the authenticated (ticket) user when impersonation is enabled.

Example 5: Drill Client to Drillbit Authentication and Encryption Enabled using Multiple Mechanisms and Drillbit to Drillbit Authentication using Default Security

The following configuration authenticates and encrypts the connection between the Drill client and Drillbit using multiple authentication mechanisms, and also authenticates and encrypts the connection between Drillbits using the Default security mechanism.

NOTE: Plain authentication not supported in this configuration.

```
drill.exec {
  security: {
    user.auth.enabled: true,
    auth.mechanisms : ["MAPRSASL", "KERBEROS"],
    auth.principal : "mapr/_host@REALM.COM",
    auth.keytab : "/opt/mapr/conf/mapr.keytab",
    user.encryption.sasl.enabled : true,
    bit.auth.enabled : true,
    bit.auth.mechanism : "MAPRSASL",
    bit.encryption.sasl.enabled : true
  },
  impersonation: {
    enabled: true,
    max_chained_user_hops: 3
  }
}
```

NOTE: Drill executes all queries as a service or process user when impersonation is disabled.

Kerberos

Drill supports Kerberos v5 network security authentication and encryption. Kerberos is a network authentication protocol built on symmetric-key cryptography. Kerberos eliminates the need to store passwords locally or send them over the network and reduces the risk of impersonation.

Kerberos provides a security infrastructure called a Kerberos Realm. A Kerberos Realm is comprised of clients, services or hosts, and a KDC (key-distribution center). The KDC is a trusted third-party service that

generates tickets to coordinate authentication between a client and server or host. Tickets are cached on the client machine, which allows for single sign-on.

Clients use a password or a special file called a “keytab” to get tickets from the KDC. Clients exchange the tickets and secret keys with the KDC and service or host to prove their identity for access to the requested service. This authentication process of exchanging tickets and secret keys runs in the background, unseen by the user trying to access the service. When a client request to access a service is granted, a unique session key is established between the client and service. The unique session key proves the authenticity of the user. The session key is used for all communication between the client and service. Kerberos also supports encryption between the client and server to prevent data theft from a man-in-the-middle attack during communication.

A KDC administrator must create the password or keytab for the clients and servers, as well as a principal (a name for the user or server identity) to securely authenticate using the Kerberos infrastructure.

NOTE: Proper setup, configuration, administration, and usage of a Kerberos environment is beyond the scope of this documentation. See the [MIT Kerberos](#) documentation for more detailed information about Kerberos.

The following sections list the prerequisites for using Kerberos with Drill and describe the authentication process.

Prerequisites

- The [Data Fabric Drill driver](#) includes the required Kerberos plugin to authenticate to secure Kerberos Drill clusters. To use Kerberos with Drill, you must have a working Kerberos infrastructure, which Drill does not provide.
- Either a ticket granting ticket (TGT) is pre-generated on the client node, or a keytab file and the client principal is available to provide in the connection URL for Kerberos authentication between the Drill client and Drill server. Drill does not generate the TGT.
- You must be working in a Linux-based or Windows Active Directory (AD) Kerberos environment with secure clusters and have a Drill server configured for Kerberos.

Client Authentication Process

This section provides a high-level overview of the Kerberos client authentication process. For this overview, assume that Kerberos credentials are present in the client.

The following diagram shows the process of authenticating a client:

1. The client sends a request for a ticket granting ticket that contains the user principal to the Kerberos KDC, a network service that supplies tickets and temporary session keys.
2. The authentication server validates the principal's identity and sends the client a ticket granting ticket and session key encrypted with a secret key. A session key is a temporary encryption key used for one login session.
3. Using the ticket granting ticket, the principal requests access to a Drillbit service from the ticket granting server.
4. The ticket granting server checks for a valid ticket granting ticket and the principal identity. If the request is valid, the ticket granting server returns a ticket granting service ticket.
5. The client uses the service ticket to request access to the Drillbit.
6. The Drillbit service has access to the keytab, a file that contains a list of keys for principals. The key allows the service to decrypt the client's ticket granting service ticket, identify the principal, and grant access.

Server Authentication Process

For Kerberos server authentication information, see the [MIT Kerberos](#) administration documentation.

Configuring Drill with Kerberos

The topics listed below provide configuration and connection information.

Configuring Authentication and Encryption

To enable authentication and encryption, you must create a Kerberos principal identity and a keytab file. You add the principal and keytab file to <DRILLINSTALL_HOME>/conf/drill-override.conf with the specified configuration parameters. In addition, you can configure a mapping from a Kerberos principal to a Drill user account. This mapping is used by a Drillbit to convert an authenticated client principal to

a corresponding Kerberos short name, which is used to determine administrator privileges for the client principal. After you complete the configuration steps, restart the Drillbit.

To enable authentication and encryption using the Kerberos mechanism, configure the following Kerberos-specific parameters in `drill-override.conf`:

 **NOTE:** Only Drill 1.11 and later supports encryption.

 **NOTE:** For client-side configuration, see [Drill Drivers](#).

Parameters	Communication Path	Description	Default
<code>drill.exec.security.auth.principal</code>	Drill client (ODBC/JDBC) to Drillbit	String representation of the Kerberos principal used by the Drillbit service.	N/A
<code>drill.exec.security.auth.keytab</code>	Drill client (ODBC/JDBC) to Drillbit	Location of the keytab file for the configured Drillbit service principal.  NOTE: The Kerberos keytab file that contains the encrypted key for the Drillbit service principal. The file should be readable by the Drillbit process user.	N/A
<code>drill.exec.security.auth.auth_to_local</code>	Drill client (ODBC/JDBC) to Drillbit	Custom rules to convert the Kerberos principal to the Kerberos short name.  NOTE: Drill uses a Hadoop Kerberos name and rules to transform the Kerberos principal provided by client to the one it will use internally as the client's identity. This client identity is used to determine administrator privileges. See Mapping from Kerberos Principal to OS user account in the Hadoop in Secure Mode documentation for details about how the rule works.	The primary name of the Kerberos principal. By default, this mapping rule extracts the first part from the provided principal. For example, if the principal format is <code><Name1>/<Name2>@realm</code> , the default rule extracts only Name1 from the principal and Name1 as the client's identity on server side.
<code>drill.exec.security.user.encryption.sasl.enabled</code>	Drill client (ODBC/JDBC) to Drillbit	Enables/disables encryption for the communication path between the Drill client and Drillbit.	false
<code>drill.exec.security.bit.auth.use_logi n_principal</code>	Drillbit to Drillbit	When set to true, the Drillbit uses the same logged in service principal configured with <code>drill.exec.security.auth.principal</code> for the Drillbit to Drillbit communication paths. When this parameter is set to false, a principal is constructed using the hostname from ZooKeeper for the remote Drillbit and keeping the primary and realm information the same as the logged in principal set by <code>drill.exec.security.auth.principal</code> .	false

Parameters	Communication Path	Description	Default
drill.exec.security.bit.encryption.sasl.enabled	Drillbit to Drillbit	Enables/disables encryption for the communication path between the Drillbits.	false

Steps to Enable Kerberos Authentication and Encryption

Complete the following steps to enable Drill to use Kerberos for authentication and encryption:

1. Create a Kerberos principal identity and a keytab file. You can create one principal for each Drill node or one principal for all Drill nodes in a cluster.

For one principal per Drill node in the cluster:

```
# kadmin
: addprinc -randkey <username>/
<FQDN>@<REALM>.COM
: ktadd -k /opt/mapr/
conf/drill.keytab <username>/
<FQDN>@<REALM>.COM
```

For one principal for all Drill nodes in the cluster:

Use <clustername> instead of <FQDN>:

```
# kadmin
: addprinc -randkey <username>/
<clustername>@<REALM>.COM
: ktadd -k /opt/mapr/
conf/drill.keytab <username>/
<clustername>@<REALM>.COM
```

IMPORTANT: When creating the Kerberos principal identity and keytab file, note the following requirements:

- The administrator must own the `drill.keytab` file and have the ability to read the file.
- The instance name must be lowercase. If `_HOST` is set as the instance name in the principal, it is replaced with the fully qualified domain name of that host for the instance name. For example, if Drill running on `host01.aws.lab` uses `drill/_HOST@<EXAMPLE>.COM` as the principal, the canonicalized principal is `drill/host01.aws.lab@<EXAMPLE>.COM`.
- When Drill runs on a secure cluster (maprsasl enabled), the username in the Drill service principal must correspond with the user running the Drill process. By default, the user is `mapr`:

```
mapr/_HOST@<EXAMPLE>.COM
```

2. Add the Kerberos principal identity, keytab file, and parameters specific to Kerberos to the `drill-override.conf` file. You can use the following configuration examples for enabling authentication, encryption, or both between the Drill client and Drillbit and between Drillbits.

Example 1: Enabling Kerberos Authentication Between the Drill Client and Drillbit

```
drill.exec: {
  cluster-id: "drillbits1",
  zk.connect:
    "qa102-81.qa.lab:5181,qa102-82.qa.lab:5181,qa102-83.qa.lab:5181",
  impersonation: {
    enabled: true,
    max_chained_user_hops: 3
  }
}
```

```

    },
    security: {
      user.auth.enabled: true,
                auth.mechanisms:
["KERBEROS"],

      auth.principal: "drill/
<clustername>@<REALM>.COM",
                auth.keytab: "/etc/
drill/conf/drill.keytab"
    }
  }
}

```

Example 2: Enabling Kerberos Authentication and Encryption Between the Drill Client and Drillbit

```

drill.exec: {
  cluster-id: "drillbits1",
  zk.connect:
"qa102-81.qa.lab:5181,qa102-82.qa.lab:5181,qa102-83.qa.lab:5181",
  impersonation: {
    enabled: true,
    max_chained_user_hops: 3
  },
  security: {
    user.auth.enabled: true,
                auth.mechanisms:
["KERBEROS"],

    auth.principal: "drill/
<clustername>@<REALM>.COM",
                auth.keytab: "/etc/
drill/conf/drill.keytab",

    user.encryption.sasl.enabled: true
  }
}
}
}

```

Example 3: Enabling Kerberos Authentication Between Drill Client and Drillbits and Between Drillbits

```

drill.exec: {
  cluster-id: "drillbits1",
  zk.connect:
"qa102-81.qa.lab:5181,qa102-82.qa.lab:5181,qa102-83.qa.lab:5181",
  impersonation: {
    enabled: true,
    max_chained_user_hops: 3
  },
  security: {
    user.auth.enabled: true,
                auth.mechanisms:
["KERBEROS"],

    auth.principal: "drill/
<clustername>@<REALM>.COM",
                auth.keytab: "/etc/
drill/conf/drill.keytab"
  }
  security.bit: {

```

Example 4: Enabling Kerberos Authentication and Encryption Between Drill Client and Drillbits and Between Drillbits

```

        auth.enabled: true,
        auth.mechanism:
"Kerberos",
    auth.use_login_principal: true
    }

```

```

drill.exec: {
  cluster-id: "drillbits1",
  zk.connect:
"qa102-81.qa.lab:5181,qa102-82.qa.la
b:5181,qa102-83.qa.lab:5181",
  impersonation: {
    enabled: true,
    max_chained_user_hops: 3
  },
  security: {

user.auth.enabled:true,
        auth.mechanisms:
["KERBEROS"],

auth.principal:"drill/
<clustername>@<REALM>.COM",
        auth.keytab:"/etc/
drill/conf/drill.keytab",

user.encryption.sasl.enabled: true
    }
    security.bit: {
        auth.enabled: true,
        auth.mechanism:
"Kerberos",

auth.use_login_principal: true,

encryption.sasl.enabled: true
    }
  }
}

```

NOTE: In examples 3 and 4 above, the Drillbit will use the same logged in service principal as configured in drill.exec.security.auth.principal.

Example 5: Enabling Kerberos Authentication and Encryption Between Drill Client and Drillbits and Between Drillbits. For Drillbit to Drillbit authentication, where the service principal is created using the hostname from ZooKeeper for a remote Drillbit as an instance name. The primary and the realm component of the service principal is used from the drill.exec.security.auth.principal parameter.

```

drill.exec: {
  cluster-id: "drillbits1",
  zk.connect:
"qa102-81.qa.lab:5181,qa102-82.qa.la
b:5181,qa102-83.qa.lab:5181",
  impersonation: {
    enabled: true,
    max_chained_user_hops: 3
  },
  security: {

user.auth.enabled:true,
        auth.mechanisms:

```

```
[ "KERBEROS" ],

auth.principal: "drill/
<clustername>@<REALM>.COM",
    auth.keytab: "/etc/
drill/conf/drill.keytab",

user.encryption.sasl.enabled: true
    }
    security.bit: {
        auth.enabled: true,
        auth.mechanism:
"Kerberos",

encryption.sasl.enabled: true
    }
}
```

NOTE: For the configuration in example 5, if the hostname of the remote Drillbit known to ZooKeeper is **host01.aws.lab**, then the service principal used by a Drillbit to authenticate with the remote Drillbit will be **drill/host01.aws.lab@<REALM>.COM**.

3. Restart the Drillbit process on each Drill node.

```
$ maprcli node services -name drill-bits -action restart -nodes <node
host names separated by a space>
```

Related concepts

[Plain Authentication](#) on page 4810

An administrator can configure Drill to use the Linux pluggable authentication module (PAM) for Plain (username and password) authentication. PAM provides an authentication module that interfaces with any installed PAM authentication entity, such as the local operating system password file (/etc/passwd) or LDAP.

Configuring Drill to Use Kerberos with Hive Metastore

To configure Drill to use Kerberos with the Hive metastore, modify the hive storage plugin in the Drill Web UI and then restart the Warden service.

NOTE: When you configure Drill to use Kerberos with the Hive metastore, Drill submits requests to the Hive metastore as the mapr superuser. If you want Drill to submit requests to the Hive metastore as any other user, configure [Drill impersonation with Hive](#) instead of performing this task. Drill impersonation works with or without Kerberos configured for the Hive metastore.

Prerequisites

The configurations described in this document have the following dependencies:

- Data Fabric cluster.
- Drill installed with Drillbits running as the mapr user.
- Supported version of Hive installed with the following:
 - Hive Metastore configured to use Kerberos authentication
 - Configured Hive remote metastore repository

NOTE: See the [Drill Support Matrix](#) on page 7754 for supported versions of Hive.

Modify the Hive Storage Plugin in Drill

Modify the Hive storage plugin configuration in the Drill Web UI based on the authorization and security scenario for the cluster. You can only access the Drill Web UI for a running Drillbit.

Complete the following steps to configure Drill to use Kerberos with Hive Metastore:

1. Navigate to `http://<drillbit_hostname>:8047`, and select the **Storage** tab.

NOTE: You can only access the Drill Web UI for a running Drillbit.

2. Click **Update** next to the hive option.
3. In the configuration window, add the `hive.metastore.sasl.enabled`, `hive.metastore.kerberos.principal`, and `hive.security.authorization.enabled` properties, as shown below, if configuration does not contain them already. Note that other properties shown may or may not be required in your environment:

```
{
  "type": "hive",
  "enabled": true,
  "configProps": {
    "hive.metastore.uris": "thrift://<metastore_hostname>:9083",
    "fs.default.name": "maprfs://",
    "hive.server2.enable.doAs": "false",
    "hive.metastore.sasl.enabled": "true",
    "hive.metastore.kerberos.principal":
    "<metastore_server_principal_name>",
    "hive.security.authorization.enabled": "true"
  }
}
```

Restart Warden

Issue the following command on all nodes to restart the Warden service:

```
service mapr-warden restart
```

If you have `cldsh` installed, you can run the following command to restart Warden on all nodes at once:

```
cldsh -a "service mapr-warden restart"
```

Connection URLs for Kerberos using JDBC Drivers to connect via SQLLine

You can use client-side connection URL parameters for Kerberos authentication in multiple combinations to authenticate a client with Drill.

Client Credentials

A client can provide its credentials in two ways:

- With a ticket granting ticket (TGT) generated on client side. The TGT must be present on client node; Drill does not generate the TGT.
- With a keytab file and the client principal provided in the user property of the connection URL.

Configuration Options

The following table lists configuration options for connection URLs. See the Connection URL Examples section for sample URLs.

Connection Parameter (Apache Drill JDBC Driver)	Description	Connection Parameter (Drill JDBC Driver)	Mandatory/Optional	Default Value
auth	Authentication mechanism. The value is deduced if not specified. Kerberos if principal is provided. Plain if a user and password is provided. A Drill client can also explicitly specify a particular authentication mechanism to use using this parameter. For example, for Kerberos along with service_name, service_host or principal and for the Plain authentication with username and password.	auth	Optional	The preference order is Kerberos and Plain.
principal	Drillbit service principal. The format of the principal is primary/instance@realm. For Kerberos, the Drill service principal is derived if the value is not provided using this configuration. service_name (primary) and service_host (instance) are used to generate a valid principal. Since the ticket or keytab contains the realm information, the realm is optional.	principal	Optional	

keytab	For Kerberos, if the client chooses to authenticate using a keytab rather than a ticket, set the keytab parameter to the location of the keytab file. The client principal must be provided through the user parameter. A Kerberos ticket is used as the default credential (It is assumed to be present on client-side. The Drill client does not generate the required credentials.)	Optional	
sasl_encrypt	When set to true, ensures that a client connects to a server with encryption capabilities. For example, Drill 1.11 Drillbits, which support client-to-drillbit encryption.	Optional	FALSE
service_name	Key name of the Drillbit service principal.	Optional	drill
service_instance	Key of the Drillbit service principal.	Optional	Since this value is usually the hostname of the node where a Drillbit is running, the default value is the Drillbit hostname is provided either through ZooKeeper or through a direct connection string.
realm	Kerberos realm name for the Drillbit service principal. The ticket or keytab contains the realm information.	Optional	

Client Encryption

A client can specify that it requires a server with encryption capabilities only by setting the

`sasl_encrypt` connection parameter to "true." If the cluster to which client is connecting has encryption disabled, the client will fail to connect to that server.

```
drill.exec {
  security: {
    user.auth.enabled: true,
    auth.mechanisms: ["KERBEROS"],
    auth.principal: "drill/serverhostname@REALM.COM",
    auth.keytab: "/etc/drill/conf/drill.keytab",
    user.encryption.sasl.enabled: true
  }
}
```

Connection URL Examples

The following five examples show the JDBC connection URL that the embedded JDBC client uses for Kerberos authentication. The first section, Example of a Simple Connection URL, includes a simple connection string and the second section, Examples of Connection URLs Used with Previously Generated TGTs, includes examples to use with previously generated TGTs.

Example of a Simple Connection URL

Example 1: TGT for Client Credentials

The simplest way to connect using Kerberos is to generate a TGT on the client side. Only specify the service principal in the JDBC connection string for the Drillbit the user wants to connect to.

```
jdbc:drill:drillbit=10.10.10.10;principal=<principal for host 10.10.10.10>
```

In this example, the Drill client uses the:

- Default `service_name`, which is **drill**.
- `service_host` from the Drillbit name provided in the connection URL, which is **10.10.10.10**.

The service principal format is `<primary>/<instance>@<realm from TGT>`. The service principal is **principal for host 10.10.10.10**.

Examples of Connection URLs Used with Previously Generated TGTs

If you do not provide a service principal in the connection string when using Kerberos authentication, then use the `service_name` or `service_host` parameters. Since these parameters are optional, their default values will be used internally (if not provided) to create a valid principal.

Examples 2 through 4 show a valid connection string for Kerberos authentication if a client has previously generated a TGT. Realm information will be extracted from the TGT if it is not provided.

NOTE: For end-to-end authentication to function, it is assumed that the proper principal for the Drillbit service is configured in the KDC.

Example 2: Drillbit Provided by Direct Connection String and Configured with a Unique Service Principal

This type of connection string is used when:

- Each Drillbit in the cluster is configured with its own service principal.
- The instance component is the host address of the Drillbit.

```
jdbc:drill:drillbit=host1;auth=kerberos
```

In this example, the Drill client uses the:

- Default `service_name`, which is **drill**.

- `service_host`, which is the Drillbit name provided in the connection URL (**host1**).

The internally created service principal will be **drill/host1@<realm from TGT>**.

Example 3: Drillbit Selected by ZooKeeper and Configured with Unique Service Principal

This type of connection string is used when the Drillbit is chosen by ZooKeeper instead of directly from the connection string.

```
jdbc:drill:zk=host01.aws.lab:5181;auth=kerberos;service_name=myDrill
```

In this example, the Drill client uses the:

- Provided `service_name`, which is **myDrill** as the primary name of the principal.
- `service_host` as the address of the Drillbit, which is chosen from the list of active drillbits that ZooKeeper provides (**host01.aws.lab:5181**).

The internally created service principal will be **myDrill/<host address from zk>@<realm from TGT>**.

Example 4: Drillbit Selected by Zookeeper and Configured with a Common Service Principal

This type of connection string is used when all Drillbits in a cluster use the same principal.

```
jdbc:drill:zk=host01.aws.lab:5181;auth=kerberos;service_name=myDrill;service_host=myDrillCluster
```

In this example, the Drill client uses the:

- Provided `service_name`, which is **myDrill**.
- `service_host`, which is **myDrillCluster**.

The internally created service principal, which will be **myDrill/myDrillCluster@<realm from TGT>**.

Example 5: Keytab for Client Credentials

If a client chooses to provide its credentials in a keytab instead of a TGT, it must also provide a principal in the user parameter. In this case, realm information will be extracted from the `/etc/krb5.conf` file on the node if it is not provided in the connection URL. All other parameters can be used as shown in the preceding examples (1-4). This connection string is for the case when all Drillbits in a cluster use the same principal.

```
jdbc:drill:zk=host01.aws.lab:5181;auth=kerberos;service_name=myDrill;service_host=myDrillCluster;keytab=<path to keytab file>;user=<client principal>
```

In this example, the Drill client:

- Will authenticate itself with the:
 - Keytab (**path to keytab file**) and
 - Principal provided in the user parameter (**client principal**)
- Uses the:
 - Provided `service_name`, which is **myDrill**.
 - `service_host`, which is **myDrillCluster**.

The internally created service principal will be **myDrill/myDrillCluster@<realm from krb5.conf>**.

Plain Authentication

An administrator can configure Drill to use the Linux pluggable authentication module (PAM) for Plain (username and password) authentication. PAM provides an authentication module that interfaces with any installed PAM authentication entity, such as the local operating system password file (/etc/passwd) or LDAP.

NOTE: Starting in EEP 5.0, Drill supports form-based authentication between the web client and Drillbit. Form-based authentication is like Plain authentication in that a user is presented with a web form where s/he enters a username and password to access restricted web pages. [Configuring Drill to Use libpam4j](#) includes configuration details. When using form-based authentication, you can also configure Drill to use SPNEGO. See [SPNEGO for HTTP Authentication](#).

When using PAM for authentication, each user with permission to run Drill queries must exist in the list of users that resides on each Drill node in the cluster. The username (including uid) and password for each user must be identical across all Drill nodes.

If you use PAM with /etc/passwd for authentication, verify that the users permitted to start the Drill process are part of the shadow user group on all nodes in the cluster. This enables Drill to read the /etc/shadow file for authentication.

NOTE: Plain authentication does not support SASL encryption. You can use [SSL/TLS for encryption](#) when Plain authentication is enabled. You can also enable [user impersonation](#) and create views to limit user access to data.

Authentication Process Overview

During the authentication process, the client passes a username and password to the Drillbit as part of the connection request, which then passes the credentials to PAM. If PAM authenticates the user, the connection request passes the authentication phase, and the connection is established. The user will be authorized to access Drill and issue queries against the filesystem or other storage plugins, such as Hive.

The following image illustrates the PAM user authentication process in Drill:

If PAM cannot authenticate the user, the connection request does not pass the authentication phase and the user will not be authorized to access Drill. The connection is terminated as AUTH_FAILED.

For more PAM information (including a JPAM User Guide), see [JPAM](#).

Configuring Plain Authentication in Drill

Drill supports the libpam and libpam4j libraries. In Drill 1.12 and later, the libpam4j library is packaged with Drill. There is no download or external dependency required to use libpam4j. Using libpam4j is recommended for Drill 1.12 and later.

NOTE: You can configure Drill to use multiple types of authentication mechanisms. For example, you can configure Drill to use Plain, Kerberos, and Data Fabric-SASL; however, only [SSL/TLS](#) is supported for encryption when Plain authentication is configured with other authentication mechanisms.

The following sections provide information for configuring Drill to use libpam4j or libpam, as well as instructions for connecting to Drill from SQLLine and BI tools when Plain authentication is enabled:

Configuring Drill to Use libpam4j

You can configure Drill to use libpam4j for Plain authentication between a client, such as ODBC, and the Drillbit.

Starting in EEP 5.0, you can configure Drill to use libpam4j for form-based authentication between a web client and Drillbit (web server). Form-based authentication is like Plain authentication in that a user is presented with a web form where s/he enters a username and password to access restricted web pages. When using form-based authentication, you can also configure Drill to use SPNEGO. See [SPNEGO for HTTP Authentication](#).

Complete the following steps to configure Plain authentication (for JDBC/ODBC clients) and form-based authentication (for the web client) in Drill:

1. Add the following configurations to the `/opt/mapr/drill/drill-<version>/conf/drill-override.conf` file:

```
drill.exec:{
  cluster-id:"drillbits1",

  zk.connect:"<zk-node-hostname>:5181,<zk-node-hostname>:5181,<zk-node-hostname>:5181",
  security:{
    auth.mechanisms:[ "PLAIN"],
  },
  security.user.auth:{
    enabled:true,
    packages += "org.apache.drill.exec.rpc.user.security",
    impl:"pam4j",
    pam_profiles:[ "sudo", "login" ]
  },
  http.auth.mechanisms:[ "FORM" ]
}
```

2. (Optional) To add or remove different PAM profiles, add or delete the profile names in the `pam_profiles` array portion of the configuration:

```
pam_profiles: [ "sudo", "login" ]
```

3. Restart the Drillbit process on each Drill node, as shown:

```
/opt/mapr/drill/drill-<version>/bin/drillbit.sh restart
```

Configuring Drill to Use libpam

You can configure Drill to use libpam for Plain authentication between a client, such as ODBC, and the Drillbit.

To configure Drill to use libpam, complete the following steps:

1. Copy the `libpam.so` file from `/opt/mapr/lib` to a directory that does not contain other Hadoop components, for example `/opt/pam/`.

2. Add the following line to `/opt/mapr/drill/drill-<version>/conf/drill-env.sh`, including the directory where the `libjpam.so` file is located, as shown:

```
export
DRILLBIT_JAVA_OPTS="$DRILLBIT_JAVA_OPTS -Djava.library.path=<directory>"
Example: export
DRILLBIT_JAVA_OPTS="$DRILLBIT_JAVA_OPTS -Djava.library.path=/opt/pam/"
```

3. Add the following configuration to the `drill.exec` block in `/opt/mapr/drill/drill-<version>/conf/drill-override.conf`:

```
drill.exec: {
  cluster-id: "drillbits1",
  zk.connect:
    "qa102-81.qa.lab:5181,qa102-82.qa.lab:5181,qa102-83.qa.lab:5181",
  impersonation: {
    enabled: true,
    max_chained_user_hops: 3
  },
  security: {
    auth.mechanisms : ["PLAIN"],
  },
  security.user.auth: {
    enabled: true,
    packages += "org.apache.drill.exec.rpc.user.security",
    impl: "pam",
    pam_profiles: [ "sudo", "login", "mapr-admin" ]
  }
}
```

4. (Optional) To add or remove different PAM profiles, add or delete the profile names in the `pam_profiles` array portion of the configuration:

```
pam_profiles: [ "sudo", "login" ]
```

5. Restart the Drillbit process on each Drill node using the [Control System](#) or issuing the `maprccli` command:

```
maprccli node services -name drill-bits -action restart -nodes
<node_hostname>
```

For `<node_hostname>`, you can use ``hostname -f`` to apply your environment variable for the hostname, as shown:

```
maprccli node services -name drill-bits -action restart -nodes
`hostname -f`
```

Or you can manually enter the `<node_hostname>`, for example:

```
maprccli node services -name drill-bits -action restart -nodes
node1.cluster.com
```

Connection URL for Plain Authentication using the Apache JDBC Driver to connect via SQLLine

When Plain authentication is enabled, each user that accesses the Drillbit process through a client, must provide username and password credentials for access.

Connecting to Drill from SQLLine

Include the `-n` and `-p` parameters with your username and password when launching SQLLine, as shown in the following example:

```
sqlline -u jdbc:drill:zk=10.10.11.112:5181 -n <username> -p <password>
```

Alternatively, you can launch SQLLine and then issue the `!connect` command to hide the password.

Complete the following steps to hide the password:

1. Run the `sqlline` script, as shown:

```
$ /etc/drill/bin/sqlline
```

2. At the prompt, enter the `!connect` command followed by

```
jdbc:drill:zk=zk=<zk name>[:<port>][,<zk name2>[:<port>]]...
```

, as shown:

```
`sqlline> !connect jdbc:drill:zk=localhost:5181 scan complete in 1385m`s
```

3. When prompted, enter a username and password; the password is hidden as it is typed, as shown:

```
Enter username for jdbc:drill:zk=localhost:5181: yourusername
Enter password for jdbc:drill:zk=localhost:5181: *****
```

Connecting to Drill from BI Tools

When you connect to Drill from a BI tool, such as Tableau, the ODBC driver prompts you for the authentication type, username, and password. For PAM, select **Basic Authentication** in the Authentication Type drop-down menu.

SSL/TLS for Encryption

You can enable SSL for Drill in a secure cluster. SSL (Secure Sockets Layer), more recently called TLS, is a security mechanism that encrypts data passed between the Drill client and Drillbit (server). SSL also provides one-way authentication through which the Drill client verifies the identity of the Drillbit.

Authentication occurs during the SSL handshake when the Drillbit (server) presents its certificate to the client, and the client checks if the certificate exists in its truststore or if the certificate is signed by a trusted CA (Certificate Authority) that exists in its truststore.

The following diagram depicts the communication between the Drill client and the Drillbit (server):

The SASL feature in Drill provides authentication and an option to encrypt data, however the encryption feature is not available when using Plain authentication. If you need to use Plain authentication (certain BI tools only use Plain authentication), you can enable SSL to encrypt data. Using SSL and SASL encryption together is strongly discouraged.

The following diagram depicts the SSL communication paths between the Drill client and Drillbit (server), including the scenario where Plain authentication is used:

NOTE: The REST API supports HTTPS. SSL is not supported for communication between Drillbits.

The following sections provide information about how to use certificates in secure clusters, enabling and configuring SSL, connection parameters, and common SSL issues.

Related concepts

[SSL Certificates](#) on page 909

Describes how certificates are used to perform authentication and encryption for websites that use the HTTPS protocol.

SSL Certificates in Clusters

The Drill server requires an SSL certificate. The certificate can be self-signed or signed by a CA (Certificate Authority).

The sections below describe how to use SSL certificates in Data Fabric clusters.

SSL in a Cluster

In a secure Data Fabric cluster, SSL is configured by default but not enabled. In a secure cluster, the keystore is configured for you. The security in a Data Fabric cluster uses a self-signed certificate. If you have a certificate signed by a certificate authority, follow the instructions for [How to Import CA \(Certificate Authority\) Signed Certificates to Data Fabric 7](#), and then enable and configure SSL.

To use SSL, enable the SSL option and then modify any of the available configuration options as needed.

- To enable SSL for the ODBC/JDBC client to Drillbit communication path, you must enable SSL on the client side and Drillbit. See [Drill Drivers](#) for client instructions. See [Configuring SSL/TLS](#) for the Drillbit.
- To enable SSL for the Drill Web UI, see [Configuring the Drill Web UI and Web API Security](#).

After you modify the configuration options, restart Drill, as shown:

```
$ maprcli node services -name drill-bits -action restart -nodes <node host names separated by a space>
```

Configuring SSL/TLS

You enable SSL in `<DRILL_INSTALL_HOME>/conf/drill-override.conf`. You can use several configuration options to customize SSL/TLS.

You must restart the Drillbit process on each node after you modify the configuration options, as shown:

```
$ maprccli node services -name drill-bits -action restart -nodes <node host
names separated by a space>
```

The following sections describe how to enable and configure SSL:

Enabling SSL

If SSL is enabled, all Drill clients, such as JDBC and ODBC, must connect to Drill servers using SSL. You enable SSL in the Drill startup configuration file, `drill-override.conf`, located in `/opt/mapr/drill/drill-<version>/conf`.

To enable SSL for Drill, set the `drill.exec.security.user.encryption.ssl.enabled` option in `drill-override.conf` to `"true."`

Configuring SSL

You can customize SSL on a Drillbit through the SSL configuration options. You can set the options from the command line (using Java system properties) in the `drill-override.conf` file or in the property file to which the Hadoop parameter `hadoop.ssl.server.conf` points (recommended).

NOTE: Specifying values in `drill-override.conf` can expose the security parameters to end users. Administrators should set these values in the Hadoop security file and restrict permissions on that file.

If a parameter is specified in multiple places, the value in the Hadoop configuration takes precedence over the Drill configuration, which takes precedence over the system property.

The Hadoop configuration is specified in the file pointed to by the `hadoop.ssl.server.conf` parameter in the Hadoop `core-site.xml` file. Typically, this parameter points to `$HADOOP_CONF/ssl-server.xml`, which contains the property names to configure SSL. Both the `core-site.xml` file and the `ssl-server.xml` file must exist in the Drill classpath. The Drill SSL configuration picks up the Hadoop SSL configuration.

NOTE: Since the Drillbit implementation is based on JSSE, several standard parameters that apply to JSSE also apply to the Drillbit. However, you typically do not need to configure JSSE parameters.

Following are the SSL configuration options with their descriptions and default values.

drill.exec.security.user.encryption.ssl.enabled

Hadoop Property Name: N/A

System Property Name: N/A

Description: Enable or disable TLS for Drill client - Drill Server communication. You must set this option in `drill-override.conf`.

Allowed Values: true or false

Drill Default: false

drill.exec.ssl.protocol

Hadoop Property Name: N/A

System Property Name: N/A

Description: The version of the TLS protocol to use.

Allowed Values: TLS, TLSV1, TLSv1.1, TLSv1.2, TLSv1.3

Drill Default: TLSv1.3 (recommended)

drill.exec.ssl.keyStoreType*Hadoop Property Name:* ssl.server.keystore.type*System Property Name:* javax.net.ssl.keyStoreType*Description:* Format of the keystore file*Allowed Values:* jks, jceks, pkcs12*Drill Default:* jks**drill.exec.ssl.keyStorePath***Hadoop Property Name:* ssl.server.keystore.location*System Property Name:* javax.net.ssl.keyStore*Description:* Location of the Java keystore file containing the Drillbit's own certificate and private key. On Windows, the specified pathname must use forward slashes, /, in place of backslashes.*Allowed Values:* Not Applicable*Drill Default:* Not Applicable**drill.exec.ssl.keyStorePassword***Hadoop Property Name:* ssl.server.keystore.password*System Property Name:*
javax.net.ssl.keyStorePassword*Description:* Password to access the private key from the keystore file. This password is used twice: To unlock the keystore file (store password), and to decrypt the private key stored in the keystore (key password) unless a key password is specified separately.*Allowed Values:* Not Applicable*Drill Default:* Not Applicable**drill.exec.ssl.keyPassword***Hadoop Property Name:*
ssl.server.keystore.keypassword*System Property Name:* Not Applicable*Description:* Password to access the private key from the keystore file. May be different from the keystore password.*Allowed Values:* Not Applicable*Drill Default:* Not Applicable**drill.exec.ssl.trustStoreType***Hadoop Property Name:* ssl.server.truststore.type*System Property Name:* javax.net.ssl.trustStoreType*Description:* Format of the truststore file*Allowed Values:* jks, jceks, pkcs12*Drill Default:* jks**drill.exec.ssl.trustStorePath***Hadoop Property Name:* ssl.server.truststore.location*System Property Name:* javax.net.ssl.trustStore*Description:* Location of the Java keystore file containing the collection of CA certificates trusted by the Drill client. On Windows, the specified pathname must use forward slashes, /, in place of backslashes.

NOTE: If the `trustStorePath` is not provided, Drill ignores the `trustStorePassword` parameter and gets the default Java truststore instead. This operation causes issues if the Java truststore has a non-default password. The Java APIs used to load the default keystore assume the default password. The only way to use the default keystore with a non-default password is to specify both the path and the password to the keystore. To work around this issue, pass the default Java truststore to the `trustStorePath` parameter.

drill.exec.ssl.trustStorePassword

Allowed Values: Not Applicable

Drill Default: Not Applicable

Hadoop Property Name: `ssl.server.truststore.password`

System Property Name:
`javax.net.ssl.trustStorePassword`

Description: Password to access the private key from the keystore file specified as the truststore.

Allowed Values: Not Applicable

Drill Default: Not Applicable

drill.exec.ssl.provider

Hadoop Property Name: Not Applicable

System Property Name: Not Applicable

Description: Changes the underlying implementation to the chosen value.

Allowed Values: OpenSSL or JDK

Drill Default: JDK

drill.exec.ssl.useHadoopConfig

Hadoop Property Name: Not Applicable

System Property Name: Not Applicable

Description: Use the setting in the Hadoop configuration file.

The Hadoop configuration is specified in the file pointed to by the `hadoop.ssl.server.conf` parameter in the `core-site.xml` file. Typically, this parameter points to `$HADOOP_CONF/ssl-server.xml` which contains the property names to configure TLS.

Allowed Values: `true` or `false`

Drill Default: `true`

Configuring SSL on Drill on Yarn (DOY)

Starting with EEP 8.1.0, you can enable SSL on Drill on Yarn through SSL configuration options. In the `drill-on-yarn.conf` file, add the `drill.yarn.http.ssl-enabled` parameter. See [Drill-on-YARN Limitations](#) on page 4728 for additional information on related limitations.

drill.yarn.http.ssl-enabled

Hadoop Property Name: Not Applicable

System Property Name: Not Applicable

Description: Use the setting in the Hadoop configuration file with the required `drill.yarn.ssl.useHadoopConfig` parameter.

Allowed Values: `true` or `false`

drill.yarn.ssl.useHadoopConfig*Drill Default:* false*Hadoop Property Name:* Not Applicable*System Property Name:* Not Applicable*Description:* Use this setting in the Hadoop configuration file.

The Hadoop configuration is specified in the file pointed to by the `hadoop.ssl.server.conf` parameter in the `core-site.xml` file. Typically, this parameter points to `$HADOOP_CONF/ssl-server.xml` which contains the property names for configuring the TLS.

Allowed Values: true or false*Drill Default:* false*JDBC Connection Parameters*

Use the SSL JDBC connection parameters and fully qualified host name to configure the JDBC connection string in SQLLine and connect to Drill.

The following table lists the parameters that you can include in the jdbc connection string using SQLLine:

NOTE: Examples are provided after the table. For additional instructions, see the [Drill JDBC Driver](#) documentation.

Parameter	Value	Required
enableTLS	true/false	[Optional] If true, TLS is enabled. If not set or set to false, TLS is not enabled.
trustStoreType	string	<p>[Optional]</p> <p>Default: JKS</p> <p>The trustStore type.</p> <p>Allowed values are :</p> <p>JKS</p> <p>PKCS12</p> <p>If the useSystemTrustStore option is set to true (on Windows only), the allowed values are:</p> <p>Windows-MY</p> <p>Windows-ROOT</p> <p>Import the certificate into the "Trusted Root Certificate Authorities" and set trustStoreType=Windows-ROOT. Also import the certificate into "Trusted Root Certificate Authorities" or "Personal" and set trustStoreType=Windows-MY.</p>

trustStorePath	string	<p>[Optional] Path to the truststore. If not provided the default Java truststore will be used. If this is not provided the trustStorePassword parameter will be ignored.</p> <p>Note that the order for looking for the default trustStore</p> <p>java-home/lib/security/jssecacerts</p> <p>then</p> <p>java-home/lib/security/cacerts</p>
trustStorePassword	string	[Optional] Password to the truststore.
disableHostVerification	true/false	<p>[Optional] If true, we will not verify that the host in the certificate is the host we are connecting to.</p> <p>False by default</p> <p>(Hostname verification follows the specification in RFC2818).</p>
disableCertificateVerification	true/false	<p>[Optional] If true we will not validate the certificate against the truststore.</p> <p>False by default.</p>
TLSProtocol	TLS, TLSV1, TLSv1.1, TLSv1.2, TLSv1.3	<p>[Optional]</p> <p>Default: TLSv1.3 (recommended)</p>
TLSHandshakeTimeout	Time in milliseconds	<p>[Optional]</p> <p>Default: 10 seconds</p> <p>In some cases, the TLS handshake may fail and leave the client hanging. This option sets the time for the client to timeout.</p>
TLSProvider	JDK/OPENSSL	<p>[Optional]</p> <p>Default: JDK</p> <p>Changes the underlying implementation to the chosen value.</p>
useSystemTrustStore	true/false	<p>[Optional, Windows only]</p> <p>Default: false</p> <p>If provided, the client will read certificates from the Windows truststore. In this case, trustStorePath and trustStorePassword, if specified, will be ignored.</p> <p>The user should set the default provider in \$JRE_HOME/lib/security/java.security to SunMSCAPI.</p> <p>The trustStoreType should be set to either Windows-MY or Windows-ROOT.</p>

Examples

The following examples show you how to connect to Drill through SQLLine with the jdbc connection string when SSL is not enabled and when SSL is enabled with and without a truststore.

No SSL/TLS

```
./sqlline -u
"jdbc:drill:schema=dfs.work;drillbit=localhost:31010;enableTLS=false"
```

SSL/TLS Enabled - No truststore

The default JSSE truststore will be tried with default password; the provided password will be ignored. If the default truststore password has been changed, this gives an error. To use the default truststore with a different password, pass the path to the default truststore with the password.

```
./sqlline -u
"jdbc:drill:schema=dfs.work;drillbit=localhost:31010;enableTLS=true;trustStorePassword=drill123"
```

SSL/TLS enabled - With truststore

```
./sqlline -u
"jdbc:drill:schema=dfs.work;drillbit=localhost:31010;enableTLS=true;trustStorePath=~/.ssl/truststore.ks;trustStorePassword=drill123"
```

ODBC Connection Parameters

Use the SSL ODBC connection parameters to configure a connection to Drill through an ODBC tool.

The following table lists the ODBC connection parameters:

 **NOTE:** The Drill ODBC driver does not support password protected PEM/CRT files or multiple CRT certificates in a single PEM/CRT file. For additional instructions, see the [Drill ODBC Driver](#) documentation.

Name	Value	Required	Description
SSL	Clear (0)	No.	<p>This option specifies whether the client uses an SSL encrypted connection to communicate with Drill.</p> <ul style="list-style-type: none">• Enabled(1):The client communicates with Drill using SSL.• Disabled(0):SSL is disabled. <p>SSL is configured independently of authentication.</p> <p>When authentication and SSL are both enabled, the driver performs the specified authentication method over an SSL connection.</p>

TLSProtocol	Empty, which defaults to tlsv12.	No	<p>This property specifies the TLS protocol version used.</p> <p>Accepted values are:</p> <ul style="list-style-type: none"> • tlsv1 • tlsv11 • tlsv12
TrustedCerts	<p>The cacerts.pem file in the \lib subfolder within the Driver's installation directory. The exact file path varies depending on the version of the driver that is installed.</p> <p>For example, the path for the Windows driver is different from the path for the Mac OS driver.</p>	No	<p>The full path of the PEM file containing Trusted CA certificates, for verifying the server. If this option is not set, then the driver defaults to using the trusted CA certificates PEM file installed by the driver.</p>
UseSystemTrustStore	Clear (0)	No	<p>This option specifies whether to use a CA certificate from the system truststore, or from a specified PEM file.</p> <ul style="list-style-type: none"> • Enabled (1): The driver verifies the connection using a certificate in the system truststore • Disabled (0): The driver verifies the connection using a specified PEM file. <p>Note: This option is only available on Windows. If using this option, import the certificate into the "Trusted Root Certificate Authorities" certificate store.</p>
DisableCertificateVerification	0	No	<p>This property specifies that the driver verifies the host certificate against the truststore. Accepted values are:</p> <ul style="list-style-type: none"> • 0: The driver verifies the certificate against the truststore. • 1: The driver does not verify the certificate against the truststore.

DisableHostVerification	0	No	<p>This property specifies if the driver verifies that the host in the certificate is the host being connected to. Accepted values are:</p> <ul style="list-style-type: none"> 0: The driver verifies the certificate against the host being connected to. 1: The driver does not verify the certificate against the host.
-------------------------	---	----	--

Avoiding Common SSL Issues

The following sections provide insight to some common error messages that you may encounter with SSL.

ERROR: No Cipher suites in common.

This is a general purpose error message that may have many reasons. The most common reason is that in order to use certain cipher suites, JSSE needs to use the private key stored in the Keystore. If this key is not accessible, JSSE filters out all cipher suites that need a private key. This effectively prunes out all available cipher suites so that no cipher suites match between the client and the server.

The private key from the keystore may be inaccessible for the following reasons:

- Missing Keystore file
- Invalid Keystore password
- Empty key password or a key password that is different from the keystore password

JSSE does not allow a key password that is null or an empty string even though it is possible to create a keystore with such a key password. Also, JSSE does not provide a system property to specify the key password. Drill provides a way to set the key password, but if you are using only system properties to configure JSSE, Drill will use the *keystore* password. If the keystore password is not the same as the key password, the key will again be inaccessible.

- Corrupt keystore

You can validate the keystore using keytool.

ERROR: SSL is enabled, but cannot be initialized due to the 'Cannot recover key' exception.

The key is protected with a password and the provided password is not correct.

ERROR: Client connection timeout.

A client connection can timeout because of networking issues or if there is a mismatch between the TLS/SSL configuration on the client and server.

Before trying to debug the TLS/SSL configuration, check if the server is reachable from the client.

If there is a mismatch between the TLS/SSL configuration, the TLS/SSL handshake between the client and server will fail. The server will silently drop the connection and the client will eventually time out. The handshake may fail due to many reasons, including:

1. The server is configured to enable TLS and the client is not (and vice versa).

- a. If the client is not configured to use TLS and the server is, the error message will be similar to the following:

```
Error: Failure in connecting to Drill:
org.apache.drill.exec.rpc.RpcException: HANDSHAKE_COMMUNICATION :
Channel closed /10.10.10.11:49907 <--> hostname/10.10.10.11:31010.
(state=,code=0)
java.sql.SQLNonTransientConnectionException: Failure in connecting to
Drill: org.apache.drill.exec.rpc.RpcException:
HANDSHAKE_COMMUNICATION : Channel closed /10.10.10.11:49907
<-->hostname/10.10.10.11:31010.
```

- b. If the server is not configured to use TLS and the client tries to connect using TLS, the error message will be similar to the following:

```
Error: Failure in connecting to Drill:
org.apache.drill.exec.rpc.NonTransientRpcException: Connecting to the
server timed out. This is sometimes due to a mismatch in the SSL
configuration between client and server. [ Exception: Timeout waiting
for task.] (state=,code=0)
```

2. The server presents a certificate to the client containing a hostname that is not valid. When the client connects to a server, the hostname the client used to connect to the server must match the name of the host the certificate was assigned to. Certificates can contain wildcards for the hostname, so if you're connecting to a Drill cluster via ZooKeeper, it would be best to have a certificate that contains wildcards that cover all the hosts on which Drill might be running. It is also important to ensure that the DNS and the hostnames of the machines in the cluster are set up consistently so that the Drillbits are registered with ZooKeeper using the same name as the name assigned in the certificate. The error message in this case is the same as the previous case:

```
Error: Failure in connecting to Drill:
org.apache.drill.exec.rpc.NonTransientRpcException: Connecting to the
server timed out. This is sometimes due to a mismatch in the SSL
configuration between client and server. [ Exception: Timeout waiting
for task.] (state=,code=0)
```

Hostname verification can be turned off if there is no way to change the host configuration or the certificate. This is generally not recommended.

Security Between ZooKeeper and Drillbits

When Drill is installed on clusters with the default security enabled, authentication is enabled between the Drillbits and ZooKeeper. The ZooKeeper znode information is secured automatically through authentication and znode ACLs. Communication between the Drillbits and Zookeeper is not encrypted.

NOTE: If you installed Drill on a cluster that does not have the default security configuration, and you are configuring custom security, you must enable authentication and manually set ACLs on the znodes.

Drill uses ZooKeeper to store certain cluster-level configuration and query profile information in znodes. A znode is an internal data tree in ZooKeeper that stores coordination and execution related information. If information in the znodes is not properly secured, cluster privacy and/or security is compromised.

ZooKeeper uses ACLs to control access to znodes and secure the information they store. Starting in Drill 1.15, you can create a custom ACL (Access Control List) on the znodes to secure data. ACLs specify sets of ids and permissions that are associated with the ids.

Starting in Drill 1.15, ACLs in secure clusters are set to `[authid: all]`, which provides full access to the authenticated user that created the znode only. Discovery znodes (znodes with the list of Drillbits) have an additional ACL set to `[world: read]` making the list of Drillbits readable by any user.

NOTE: View the [drill-override-example.conf](#) file to see example ACL configurations.

Securing znodes

Complete the following steps to create a custom ACL and secure znodes:

1. Write a class that implements the `ZKACLProvider` interface. This class will contain the ACLs that need to be set on the znodes. You can use the [ZKSecureACLProvider class](#) as a sample reference.
2. Add the following dependency to the pom file of the project module created:

```
<groupId>org.apache.drill.exec</groupId>
<artifactId>drill-java-exec</artifactId>
```

3. Refer to the steps listed at <https://drill.apache.org/docs/manually-adding-custom-functions-to-drill/> to create a JAR and then add the JAR to Drill's classpath.
4. In `/opt/mapr/drill/drill-<version>/conf/drill-override.conf`, set `zk.acl_provider` to the `ZKACLProviderTemplate` type.
5. Restart Drill. When you restart Drill, the ACL, as mentioned in your custom class, is applied to the znode created when Drill starts.

NOTE: Existing ACLs for persistent znodes will not be affected if a Drillbit is restarted with a different ACL setting. ACLs are applied only at znode creation time. Drill does not recreate any znode that is already present. If you want to change an ACL for existing znodes, connect to the ZooKeeper server using `zkCli` and then use option a or b, as described:

- a) Shutdown Drillbits, delete the persistent znodes, change the ACL settings, and restart the Drillbit.
- b) Manually change the ACLs on the existing znodes to reflect the new ACL settings, using the `setACL` command in the `zkCli`.

For either option to work, an authenticated connection between the `zkCli` and ZooKeeper Server must be established.

For additional information, refer to:

- [ZooKeeper access control using ACLs](#)
- [ZooKeeper and SASL](#)

Configuring Drill Web UI and Web API Security

The Drill web client and web API communicate with web browsers or web tools, like `curl`, through the HTTP or HTTPS. Drill uses HTTP by default.

Drill supports [form-based \(similar to Plain authentication\)](#) and [SPNEGO](#) authentication mechanisms to authenticate the communication between the web client and web browser or web tools. Drill supports SSL/TLS for encryption with form-based and SPNEGO authentication.

An administrator can configure security mechanisms and [set up Drill Web UI administrators and administrator-user groups](#) to control access to the Drill Web UI and Web API client applications. For example, limiting user access to Drill Web UI functionality, such as viewing or canceling queries submitted by other users.

**NOTE:**

- The Drill web server does not support mapr-SASL (tickets).
- With Drill Web UI security in place, users without administrator privileges must execute the SHOW SCHEMAS command in the Drill Web UI Query page to see storage plugin configuration information.

Form-Based Authentication

In EEP 5.0 and later, Drill supports form-based authentication between the web client and Drillbit. Form-based authentication is like [Plain Authentication](#) in that a user is presented with a web form where s/he enters a username and password to access restricted web pages. Form-based authentication also uses the Linux PAM (Pluggable Authentication Module).

[Configuring Drill to Use libpam4j](#) provides configuration details. When using form-based authentication, you can also configure Drill to use [SPNEGO for HTTP Authentication](#) and SSL/TLS for encryption.

SSO with OpenID Authentication

Starting from EEP 9.4.0, Drill supports a new Web-UI authentication method – OpenID.

For details, see [Configuring SSO with OpenID in Drill](#) on page 4830.

HTTPS Support

The Drill Web UI supports the HTTPS protocol for encryption. With the default security configuration, HTTPS is enabled for Drill and it uses SSL trust- and keystore, which comes with cluster installation.

To use custom certificates, see [SSL Certificates in Clusters](#).

The following example shows the default HTTPS configuration in <DRILL_INSTALL_HOME>/conf/drill-distrib.conf for a secure cluster installation:

```
drill.exec: {
    http.ssl_enabled: true,
    ssl.useHadoopConfig: true
}
```

You can configure additional parameters:

Drill Property Name	Hadoop Property Name	System Property Name	Description
drill.exec.http.ssl_enabled:			Enable or disable communication. Y
drill.exec.ssl.keyStorePath	ssl.server.keystore.location	javax.net.ssl.keyStore	Location of the Ja certificate and pri pathname must u
drill.exec.ssl.keyStorePassword	ssl.server.keystore.password	javax.net.ssl.keyStorePassword	Password to acce password is used password), and to (key password) u
drill.exec.ssl.keyPassword	ssl.server.keystore.keypassword		Password to acce be different from

drill.exec.ssl.trustStorePath	ssl.server.truststore.location	javax.net.ssl.trustStore	Location of the Java certificates truststore. The path name must be an absolute path.
drill.exec.ssl.trustStorePassword	ssl.server.truststore.password	javax.net.ssl.trustStorePassword	Password to access the truststore, specified as the t parameter.
drill.exec.ssl.useHadoopConfig			Use the setting in the hadoop configuration is set to true. Typically, this parameter is set to true in the ssl-server.xml when using TLS.  NOTE: Verifying the symbolic link is located in the symbolic link for example: <DRILL_...>

Setting up Web UI Administrators and Administrator-User Groups

The `security.admin.user_groups` and `security.admin.users` options set the administrative users when authentication is enabled.

Users listed in `security.admin.users` and the users belonging to the groups listed in `security.admin.user_groups` get administrative privileges. By default, these options are set to the username and groups of the user who started the Drill process. You can modify these options from the Drill Web UI or using the [ALTER SYSTEM](#) command.

An administrative user that authenticates to a Drillbit through Data Fabric-SASL, Kerberos, Plain mechanism or through the HTTPS web interface can modify the `security.admin.user_groups` and `security.admin.users` options. The administrator can add or remove user names or user groups.

The `security.admin.user_groups` and `security.admin.users` options allow a single user/group name or a comma separated list of user/group names. When you view these options in the Drill Web UI, dummy default strings appear until the user explicitly changes the values.

Authenticated administrative users can view the current administrative user and administrative user groups on the Drill Web UI landing page (<https://<node-ip-address>:8047>) in the *Encryption Info* section.

Drill REST API and Web UI

This topic provides information about the Drill REST API and Web UI, including permission requirements.

If Drill has authentication enabled, you must supply credentials when using the Drill REST API.

Although Drill (in HPE Data Fabric) does not support HTTP basic authentication, you can work around this if your HTTP client saves cookies between requests. As a workaround, save the authenticated cookie to a file and then use the cookie in subsequent requests, as shown in the following example:

```
//Log in and save the authenticated cookie to a file:

curl -X POST \
  -H "Content-Type: application/x-www-form-urlencoded" \
  -k -c cookies.txt -s \
  -d "j_username=DRILL_USER" \
  -d "j_password=DRILL_PASSWORD" \
  https://HOSTNAME:8047/j_security_check

//In subsequent requests, use the cookie from that request:
```

```
curl -kv \
  -b cookies.txt \
  -X POST \
  -H "Content-Type: application/json" \
  -d @/tmp/hive-storage-plugin.json
https://HOSTNAME:8047/storage/hive.json
```

NOTE: The session remains active for one hour. You can increase the session time through the `drill.exec.http.session_max_idle_secs` option in `drill-override.conf`:

```
drill.exec: {
  http: {
    session_max_idle_secs: 86400, # 24hr
  }
}
```

REST API Methods and Web UI Functions

The following table and subsections describe requests and privilege levels for accessing the REST API methods and corresponding Drill Web UI functions. Privileges in the table are listed as AMDIN, USER, and ALL. ALL indicates privileges given to both the user and administrator.

Path	Request Type	Output Type	Functionality	Privileges
/	GET	text/html	Returns Drillbit stats in a table in HTML format.	ALL
/stats.json	GET	application/json	Returns Drillbit stats such as ports and max direct memory in json format.	ALL
/status	GET	text/html	Returns Running!	ALL
/options.json	GET	application/json	Returns a list of options. Each option consists of name-value-type-kind (for example: (boot system datatype).	ALL
/options	GET	text/html	Returns an HTML table where each row is a form containing the option details and ability to modify the option values.	ALL
/option/{optionName}	POST	text/html	Updates the options and calls <code>getSystemOptions</code> to display list of options.	ADMIN
/storage.json	GET	application/json	Returns a list of storage plugin wrappers each containing name-config (instance of <code>StoragePluginConfig</code>) and enables the storage plugin configuration.	ADMIN

/storage	GET	text/html	Returns an HTML page with sections that contain: <ul style="list-style-type: none"> a table where each row is a form containing the plugin button for update page link and a button to disable the plugin. a table where each row is a form containing the plugin button for update page and a button to enable the plugin. 	ADMIN
/storage/{name}.json	GET	application/json	Returns a plugin config wrapper for the requested web page.	ADMIN
/storage/{name}	GET	text/html	Returns an HTML page that has an editable text box for configuration editing, followed by buttons for creating, updating, and deleting. Each of the buttons make calls that generate the new page again.	ADMIN
/storage/{name}/enable/{val}	GET	application/json	Updates the storage plugin status. Returns success or failure.	ADMIN
/storage/{name}.json	DELETE	application/json	Deletes the storage plugin. Returns success or failure.	ADMIN
/storage/{name}/delete	GET	application/json	Same as deletePluginJSON but a GET instead of a DELETE request.	ADMIN
/storage/{name}.json	POST	application/json	Creates or updates the storage plugin. Returns success or failure. Expects JSON input.	ADMIN
/storage/{name}	POST	application/json	Same as createOrUpdatePluginJSON expects JSON or FORM input.	ADMIN
/profiles.json	GET	application/json	Returns currently running and completed profiles from PStore. For each profile a queryId, startTime, foremanAddress, query, user, and state is returned. Each list (running and completed) is organized in reverse chronological order.	ADMIN, USER
/profiles	GET	text/html	Generates an HTML page from the data returned by getProfilesJSON with a hyperlink to a detailed query page.	ADMIN, USER
/profiles/{queryid}.json	GET	application/json	Returns the entire profile in JSON.	ADMIN, USER
/profiles/{queryid}	GET	text/html	Returns a complex profile page.	ADMIN, USER
/profiles/cancel/{queryid}	GET	text/html	Cancels the given query and sends a message.	ADMIN, USER
/query	GET	text/html	Gets the query input page.	ALL

/query.json	POST	application/json	Submits a query and waits until it is completed and then returns the results as one big JSON object.	ALL
/query	POST	text/html	Returns the results of submitQueryJSON in an HTML table.	ALL
/status/metrics	GET	application/json	Returns a page that fetches metric info from resource, status, and metrics.	ALL
/status/threads	GET	text/html	Returns a page that fetches metric information from resource, status, and threads.	ALL
/login	GET	text/html	Returns an HTML log in page. If the user is already logged in, returns the home page. If the URL contains a redirect, sets the redirect URI for the session and forwards the user to the redirect page after the user is successfully logged in.	ALL
/login	POST	text/html	Returns a validation error for incorrect credentials.	ALL
/logout	GET	text/html	Ends a session.	ALL

GET /profiles.json

- ADMIN - gets all profiles on the system.
- USER - only the profiles of the queries the user has launched.

GET /profiles

- ADMIN - gets all profiles on the system.
- USER - only the profiles of the queries the user has launched.

GET /profiles/{queryid}.json

- ADMIN - return the profile.
- USER - if the query is launched the by the requesting user return it. Otherwise, return an error saying no such profile exists.

GET /profiles/{queryid}

- ADMIN - return the profile.
- USER - if the query is launched the by the requesting user return it. Otherwise, return an error saying no such profile exists

GET /profiles/cancel/{queryid}

- ADMIN - can cancel the query.
- USER - cancel the query only if the query is launched by the user requesting the cancellation.

Related concepts

[Securing Drill](#) on page 4776

An administrator can install Drill with the default security configuration or manually configure custom security for Drill.

More information

<https://drill.apache.org/docs/rest-api/>

Configuring SSO with OpenID in Drill

Describes the procedure to Configure SSO with OpenID in Drill.

SSO with OpenID Configuration in Drill

Starting from EEP 9.4.0, Drill supports a new Web-UI authentication method – OpenID.

OpenID Options

The following options are used to configure OpenID authentication:

Option name	Possible values	Description
<code>drill.exec.http.auth.oidc.provider.endpoint</code>	Any string	The URL of the OpenID provider, for example: <code>https://node1.cluster.com:6443</code>
<code>drill.exec.http.auth.oidc.client.id</code>	Any string	OAuth 2.0 Client Identifier valid at the Authorization Server
<code>drill.exec.http.auth.oidc.client.secret</code>	Any string	The client secret known only by the Client and the Authorization Server
<code>drill.exec.http.auth.oidc.claim.identifying.user</code>	Any string	Claim that identifies the authenticated user. Default value: <code>sub</code>
<code>drill.exec.http.auth.oidc.useMapRConfig</code>	boolean	Use the cluster-level SSO parameters. If set to true, none of any above option is required, Drill will configure OpenID authentication automatically. Default value: <code>false</code>

Enable OpenID Authentication

OpenID authentication is enabled by setting the `drill.exec.http.auth.mechanisms` option to `["OPENID"]` as follows:

 **IMPORTANT:** The value is case-sensitive

- Set the value to `["OPENID"]`, for example:

```
drill.exec.http.auth.mechanisms: ["OPENID"]
```

Or

- You can set multiple authentication methods, for example:

```
drill.exec.http.auth.mechanisms: ["OPENID", "FORM"]
```

Automatic configuration of SSO with OpenID

- If you have set or reset any cluster-level SSO parameters, run `configure.sh -R`.
`configure` script verifies whether the cluster SSO is set or reset, and configures Drill Web-UI security accordingly in `drill-distrib.conf` by setting the `drill.exec.http.auth.mechanisms` and `drill.exec.http.auth.oidc.useMapRConfig` options. See [Drill Properties](#) on page 4745 for details on `drill-distrib.conf` options.
- If you have only changed the cluster-level SSO parameters, restart the Drill. This is sufficient to apply the new values.

Manually Enable the SSO with OpenID

To manually configure SSO with OpenID in Drill, set `drill.exec.http.auth.oidc.useMapRConfig` to `false` in [drill-override.conf](#). This makes Drill to use the following boot options instead of the cluster-level SSO parameters:

- `drill.exec.http.auth.oidc.provider.endpoint`
- `drill.exec.http.auth.oidc.client.id`
- `drill.exec.http.auth.oidc.client.secret`
- `drill.exec.http.auth.oidc.claim.identifying.user`

Manually disable SSO with OpenID

To disable SSO with OpenID in Drill, set `drill.exec.http.auth.mechanisms` option to value without `OPENID` in [drill-override.conf](#). For example, to enable only form-based authentication, use:

```
drill.exec.http.auth.mechanisms: ["FORM"]
```

Authorization

The authorization process remains the same as for other authentication methods. For details, see [Setting up Web UI Administrators and Administrator-User Groups](#) on page 4826.

Troubleshooting

Issue: SSO button is inactive with auto-configuration

Ensure the cluster-level SSO parameters are set and can be retrieved with `cluster getsssoconf` on page 2339 command.

SPNEGO for HTTP Authentication

Drill 1.13 and later supports the Simple and Protected GSS-API Negotiation mechanism (SPNEGO) to extend the Kerberos-based single sign-on authentication mechanism to HTTP. An administrator configures the web server (Drillbit) to use SPNEGO for authentication. Depending on the system, either the administrator or the user configures the client (web browser or web client tool) to use SPNEGO for authentication.

An administrator can configure both FORM (username and password) and SPNEGO authentication together, which provides the ability for clients with different security preferences to connect to the same Drill cluster. When a client (a web browser or a web client tool, such as `curl`) requests access to a secured page from the web server (Drillbit), the SPNEGO mechanism uses tokens to perform a handshake that authenticates the client browser and the web server.

The Drill Web UI provides two possible log in options for a user depending on the configuration. If a user selects FORM, s/he must enter their username and password to access restricted pages in the Drill Web

UI. The user is authenticated through PAM. If the user selects SPNEGO, the user is automatically logged in if they are an authenticated Kerberos user. If accessing a protected page directly, the user is redirected to the authentication log in page. If the client fails to authenticate using SPNEGO, an error page displays with an option to use FORM authentication, assuming FORM authentication is configured on the server side.

Browser Support

The following browsers were tested with Drill configured to use SPNEGO authentication:

- Firefox
- Chrome
- Safari
- Internet Explorer
- Web client tool, such as curl

Prerequisites

SPNEGO authentication for Drill requires the following:

- Drill 1.13 or later installed on each node.
- A working Kerberos infrastructure, which Drill does not provide.
- A Linux-based or Windows Active Directory (AD) Kerberos environment with secure clusters and a Drill server configured for Kerberos.
- Kerberos principal and keytab on each web server (Drillbit) that will use SPNEGO for authentication.
- Kerberos Ticket Granting Ticket on the client machine for the user accessing the Drillbit (web server).
- Drill web server configured for SPNEGO.

Configuring SPNEGO on the Web Server and Web Client

The following sections provide the steps that an administrator can follow to configure SPNEGO on the web server (Drillbit). An administrator or a user can follow the steps for configuring the web browser or client tool.

Configuring SPNEGO on the Drillbit (Web Server)

To configure SPNEGO on the web server, complete the following steps:

1. Generate a Kerberos principal on each web server that will receive inbound SPNEGO traffic. Each principal must have a corresponding keytab. The principal must have the following form:

```
"HTTP/<client-known-server-hostname@realm>"
```

Example: "HTTP/example.QA.LAB@QA.LAB"

//In this example, the client known server hostname is example.QA.LAB.

NOTE: If HTTPS is enabled on the Drillbit (web server), the SPNEGO principal should also start with "HTTP/", not "HTTPS/" even though the URL includes HTTPS.

2. Update the /opt/mapr/drill/drill-<version>/conf/drill-override.conf file on each Drillbit with the following server-side SPNEGO configurations:

- To enable SPNEGO, add the following configuration to `drill-override.conf`:

```
impersonation: {
    enabled: true,
    max_chained_user_hops: 3
},
drill.exec.http: {
    spnego.auth.principal: "HTTP/hostname@realm",
    spnego.auth.keytab: "path/to/keytab",
    auth.mechanisms: ["SPNEGO"]
}
//The default authentication mechanism is "FORM".
```

- To enable SPNEGO and FORM authentication, add the following configuration to `drill-override.conf`:

```
impersonation: {
    enabled: true,
    max_chained_user_hops: 3
},
security.user.auth: {
    enabled: true,
    packages +=
"org.apache.drill.exec.rpc.user.security",
    impl: "pam4j",
    pam_profiles: [ "sudo", "login" ]
}
drill.exec.http: {
    spnego.auth.principal: "HTTP/hostname@realm",
    spnego.auth.keytab: "path/to/keytab",
    auth.mechanisms: ["SPNEGO", "FORM"]
}
}
```

3. (Optional) To configure the mapping from a Kerberos principal to a user account used by Drill, update the `drill.exec.security.auth.auth_to_local` property in the `drill-override.conf` file with custom rules, as described in [Mapping from Kerberos Principal to OS user account](#).

NOTE: Drill uses a Hadoop Kerberos name and rules to transform the client Kerberos principal to the principal Drill uses internally as the client's identity. By default, this mapping rule extracts the first portion from the provided principal. For example, if the principal format is `Name1/Name2@realm`, the default rule extracts only `Name1` from the principal and stores `Name1` as the client's identity on server side. Drill uses the short name, for example `Name1`, as the user account known to Drill. This user account name is used to determine if the authenticated user has administrative privileges.

Configuring SPNEGO on the Client

An administrator or user can configure SPNEGO on the client (web browser or client tools, such as `curl`). To configure SPNEGO on the client, a Kerberos Ticket Granting Ticket must exist for the user accessing the web server. The Kerberos Ticket Granting Ticket generated on the client side is used by the web client to get a service ticket from the KDC. This service ticket is used to generate a SPNEGO token, which is presented to the web server for authentication.

The client should use the same web server hostname (as configured in the server-side principal) to access the Drill Web Console. If the server hostname differs, SPNEGO authentication will fail. For example, if the server principal is `"HTTP/example.QA.LAB@QA.LAB"`, the client should use `http://example.QA.LAB:8047` as the Drill Web Console URL.

The following sections provide instructions for configuring the supported client-side browsers:

Firefox

To configure Firefox to use a negotiation dialog, such as SPNEGO to authenticate, complete the following steps:

1. Go to **About > Config**, and accept the warnings.
2. Navigate to the network settings.
3. Set `network.negotiate-auth.delegation-uris` to "`http://,https://`".
4. Set `network.negotiate-auth.trusted-uris` to "`http://,https://`".

Chrome

For MacOS or Linux, add the `--auth-server-whitelist` parameter to the `google-chrome` command. For example, to run Chrome from a Linux prompt, run the `google-chrome` command, as shown:

```
google-chrome --auth-server-whitelist = "hostname/domain"
Example: google-chrome --auth-server-whitelist = "example.QA.LAB"
```

Safari

No configuration is required for Safari. Safari automatically authenticates using SPNEGO when requested by the server.

Internet Explorer

To configure Internet Explorer to use a negotiation dialog, such as SPNEGO to authenticate, complete the following steps:

1. Go to **Tools > Options > Security > Local Intranet > Sites**, and select all options.
2. Select **Advanced**, and add one or both of the following URLs to server:
 - `http://`
 - `https://`

NOTE: Make sure you use the hostname of the Drillbit in the URL.
3. Close the **Advanced** tab, and click **OK**.
4. Go to **Tools > Options > Advanced > Security** (in the checkbox list), and enable the **Integrated Windows Authentication** option.
5. Click **OK**.
6. Close and reopen IE. You can browse to your Spengo protected resource.

REST API

You can use CURL commands to authenticate using SPNEGO and access secure web resources over REST.

Issue the following `curl` command to log in using SPNEGO, and save the authenticated session cookie to a file, such as `cookie.txt`, as shown:

```
curl -v --negotiate -c cookie.txt -u : http://<hostname>:8047/spnegoLogin
```

Use the authenticated session cookie stored in the file, for example `cookie.txt`, to access the Drill Web Console pages, as shown in the following example:

```
curl -v --negotiate -b cookie.txt -u : http://<hostname>:8047/query
Example: curl -v --negotiate -b cookie.txt -u : http://
example.QA.LAB:8047/query
```

Using ACEs on Views to Limit Data Access

Describes how to use access control expressions to limit data access for Views.

[Apache Drill](#) on page 4676 is a distributed SQL query layer that runs on the data platform. You can enable [user impersonation](#) and [create views](#) in Drill to control user access to data stored in the data platform at the row and column levels. Access to data is based on file permissions set on the data (source files) and on the view definition files.

In addition to standard POSIX permissions, [ACEs \(access control expressions\)](#) are supported to secure data in the distributed filesystem. ACEs are a flexible access control mechanism that applies to files, tables, and streams. [Setting an ACE \(access control expression\)](#) on a file modifies the file permission to honor the [ACE](#) setting. Drill honors [ACE](#) set on Drill view files and on the source files that views access.

Each [Drill view](#) created has an associated view definition file, with a `.view.drill` extension, on which you can set ACEs to secure the view.

Example

Frank creates a [workspace](#) in the [dfs storage plugin configuration](#) in Drill that points to his home directory in the distributed filesystem. He then uses Drill to create a table named “employees” that he and the HR group can access:

```
-rwxr----- frank:hr /user/frank/employees
```

Joe, a member of the HR and MGR groups, creates a view named `emp_mgr_view` in his home directory to share a subset of the employees data with managers that belong to the MGR group:

```
-rwxr----- joe:mgr /user/joe/emp_mgr_view.drill.view
```

Managers in the MGR group have read permission on the `emp_mgr_view.drill.view` file so they can query the `emp_mgr_view` that Joe created and they can create new views from his view.

Setting [ACE](#) on the underlying data source (the “employees” table) or on the view file (`emp_mgr_view.drill.view`) that accesses the underlying data source resets the POSIX mode bits to match the permissions granted through [ACE](#) settings.

For example, if Frank issues the following command to apply an [ACE](#) to the “employees” table, a user must be a member of the EXEC group to read data in the “employees” table:

```
hadoop mfs -setace -R -readfile 'g:exec' employees
```

Anyone in the HR group that previously had access to the table can no longer access the table data unless they also belong to the EXEC group.

Running the `-getace` command on the table lists the [ACE](#) settings on the table:

```
hadoop mfs -getace /user/frank/employees
```

```
Path: /user/frank/employees
readfile: g:exec
writefile:
executefile:
readdir:
addchild:
deletechild:
lookupdir:
inherit: true
mode: -----
```

Similarly, if Joe issues the following command on the `emp_mgr_view.drill.view` file, only members of the HR group can read the file. Users that belong to the MGR group can no longer access the data through the view, unless they also belong to the HR group.

```
hadoop mfs -setace -R -readfile 'g:hr' emp_mgr_view.drill.view
```

Running the `-getace` command on view file shows the [ACE](#) settings on the file:

```
hadoop mfs -getace /user/joe/emp_mgr_view.drill.view
```

```
Path: /user/joe/emp_mgr_view.drill.view
readfile: g:hr
writefile:
executefile:
readdir:
addchild:
deletechild:
lookupdir:
inherit: true
mode: -----
```

You may also want to view another [File ACE Example](#) on page 2133.

Data Fabric Drill Drivers

HPE Data Fabric provides Drill ODBC and JDBC drivers that you can download and use to connect Drill to BI tools. The drivers are updated periodically to include support for new functionality in Drill.

The following table provides links to driver download sites and documentation:

IMPORTANT: To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see [Using the HPE Data Fabric Token-Authenticated Internet Repository](#) on page 153.

Driver	Driver Download Site	Driver Documentation
Drill ODBC Driver	All versions of the Drill ODBC driver are located at https://package.ezmeral.hpe.com/tools/MapR-ODBC/MapR_Drill/ .	<ul style="list-style-type: none"> Information about the driver, including Drill driver version compatibility and important messages, is located at Drill ODBC Driver on page 4851. Driver documentation, including installation and configuration instructions, is located in the Drill ODBC Driver PDF file. How to Connect to Drill from Tableau on Windows on page 4853

Driver	Driver Download Site	Driver Documentation
Drill JDBC Driver	All versions of the Drill JDBC driver are located at https://package.ezmeral.hpe.com/tools/MapR-JDBC/MapR_Drill/ .	<ul style="list-style-type: none"> Information about the driver, including Drill driver version compatibility and important messages, is located at Drill JDBC Drivers on page 4837. Driver documentation, including installation and configuration instructions, is located in the Drill JDBC Driver PDF file.

Drill JDBC Drivers

Download the Drill JDBC driver and use it on all platforms to connect BI tools, such as SquirrelL to Drill.

The Drill JDBC driver provides read-only access to Drill data sources, and:

- This driver is a modified version of the Apache Drill JDBC Driver with different dependencies, and support for MaprSasl authentication.
- This driver cannot be used with an Apache Drill cluster, and conversely, the standard Apache Drill JDBC driver cannot be used with the HPE Drill cluster.

Drill JDBC Driver Download

Use the driver version that matches the version of the installed Drill cluster. Older driver versions may not be compatible with newer Drill versions.

Starting with **EEP-9.4.0** or higher, you can retrieve a compatible JDBC driver directly from a cluster that has the `mapr-drill-internal` package installed. You can find the driver in following path:

```
$DRILL_HOME/jars/jdbc-driver/drill-jdbc-all-<drill-version>.jar
```

The following table provides link to the download location for the Drill JDBC drivers that compatible with each of the Drill versions listed:

IMPORTANT: To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see [Using the HPE Data Fabric Token-Authenticated Internet Repository](#) on page 153.

Drill Version	JDBC Version
EEP-9.4.0+ or Drill 1.21.2.100+	1.21.2.100

NOTE: If you're using version EEP 9.3.2 or earlier, use the [Drill JDBC Drivers documentation from core 7.8](#)

Driver Class

The Driver Class is the same as the Apache Drill JDBC Driver Class, as follows:

```
org.apache.drill.jdbc.Driver
```

Authentication methods

Drill JDBC driver supports the following authentication methods:

- MaprSasl (default authentication method for secured cluster).
- Plain.
- [Kerberos](#).

The authentication method is specified with auth [connection string parameter](#).

IMPORTANT: When the HPE Cluster is secured, even if you set auth=plain, the client uses the MaprSasl authentication for connecting to the ZooKeeper on [Random Connection](#), however, authentication to drillbit uses auth=plain parameter.

JDBC Connection String

The Drill JDBC Driver connection string prefix is: jdbc:drill:.*.

The Driver supports two types of connections, **Direct** and **Random**.

Direct connection

The Direct connection is a straightforward connection, allows you to connect to a specific drillbit or multiple drillbits, that you define.

The general schema is:

```
jdbc:drill:drillbit=<hostname>[:<port>][,<hostname2>[:<port>],...];
[propertyname=propertyValue[;propertyName2=propertyValue2;...]]
```

For example:

```
jdbc:drill:drillbit=node1.cluster.com:31010;auth=maprsasl
```

or you can provide a list of drillbits to connect to:

```
jdbc:drill:drillbit=node1.cluster.com:31010,node2.cluste.com:31010;auth=maprsasl
```

The JDBC driver attempts to connect **to any node** from the list until a successful connection is established. The order of nodes in the connection string does not guarantee the order in which the client attempts to connect to the drillbits. The client attempts to connect to a node n times, as defined by the `tries` parameter, or 5 times by default.

The default drillbit node port is 31010. If this port has not been changed, you can omit it from the connection string.

Random connection

The Random connection allows the client to retrieve a list of **active** drillbit nodes from the ZooKeeper to connect to.

The general schema is:

```
jdbc:drill:zk=<zk host name>:<port>[,<zk host name2>:<port>...]<directory>/
<cluster ID>;[propertyName=propertyValue[;propertyName2=propertyValue2;...]]
```

For example:

```
jdbc:drill:zk=node1.cluster.com:5181/drill/
hpe.cluster-drillbits;auth=maprsasl
```

or you can provide multiple ZooKeeper nodes:

```
jdbc:drill:zk=node1.cluster.com:5181,node2.cluste.com:5181/drill/
hpe.cluster-drillbits;auth=maprsasl
```

The client attempts to connect to each ZooKeeper node **in the specified order**. If the connection to one node fails, the client proceeds to the next node in the list until all nodes are tried or a connection is

established successfully. By default, the driver will attempt to connect to each node up to 15 times, with a **500 ms timeout** for each attempt, before reporting failure.

<directory>/<cluster ID> is optional if you use Sqlline client since it retrieves the relevant values from this node drillbit configuration.

After establishing a connection with a ZooKeeper node and retrieving the list of active drillbit nodes, the driver behaves exactly the same as for a **direct** connection. In the JDBC driver, ZooKeeper is used solely to retrieve the active drillbits for the corresponding cluster.

JDBC connection string parameters

The JDBC driver supports various parameters. Following table lists some of parameters:

Table

Parameter	Default Value	Allowed values	Description
auth	-	<ul style="list-style-type: none"> maprsasl plain kerberos 	Authentication method.
schema	-	Name of enabled storage plugin	The name of a storage plugin configuration to use as the default for queries. For example,schema=hive.
enableTLS	false	true false	To enable/disable TLS encryption..
trustStoreType	JKS	JKS PKC12 Windows-MY(Windows only) Windows-ROOT(Windows only)	Type of the trust store. This option is considered only if enableTLS is set to true.
trustStorePath	-	String value	Path to the truststore. If value is not provided, the default Java truststore will be used. If the default Java truststore is not available, the trustStorePassword parameter will be ignored. Note that The order of looking for the default truststore then will be in java-home/lib/security/jssecacerts.
trustStorePassword	-	String value	Password to the truststore

Table (Continued)

Parameter	Default Value	Allowed values	Description
TLSHandshakeTimeout	10000	numeric value, time in milliseconds	This option sets the time for the client to time out. If this value is not set, the TLS handshake may fail and leave the client in nonresponsive state.
TLSProvider	JDK	JDK OPENSSL	Changes the underlying implementation to the chosen value.
useSystemTrustStore	false	true false	Windows only If provided, the client reads certificates from the Windows truststore. In this case, trustStorePath and ustStorePassword, if specified, will be ignored. You must set default provider in \$JRE_HOME/lib/security/java.security to SunMSCAPI. The trustStoreType must be set to either Windows-MY or Windows-ROOT.
disableHostVerification	false	true false	If set to true, the driver will not verify whether the host in the certificate matches the host being connected to. Hostname verification follows the specification outlined in RFC 2818. This option is considered only if enableTLS is set to true.
disableCertificateVerification	false	true false	If set to true, the driver will not validate the certificate against the truststore. This option is considered only if enableTLS is set to true.
TLSProtocol	TLSv1.3	TLS TLSV1 TLSv1.1 TLSv1.2 TLSv1.3	Version of TLS protocol. This option is considered only if enableTLS is set to true.

Table (Continued)

Parameter	Default Value	Allowed values	Description
tries	5	numeric value	The maximum number of unique drillbits to which the client will attempt to establish a successful connection.
quoting_identifiers	`	<div> ` " [</div>	Identifier quotes.

Connecting to Drill via the Drill Shell (SQLLine)

See [Connecting to Drill via the Drill Shell \(SQLLine\)](#) on page 4841.

Driver Limitations

When using MapR-SASL with JDBC or ODBC drivers, there is no way to specify the target cluster name as part of the connection parameters. MapR-SASL reads the first entry in the `/opt/mapr/conf/mapr-clusters.conf` file and assumes it is the target cluster name.

For example, if the `mapr-clusters.conf` file has an entry for 'cluster1' followed by an entry for 'cluster2' and you want to connect to a node in 'cluster2', authentication fails. As a workaround, manually switch the order of entries in the `mapr-clusters.conf` file.

Related concepts

[Connecting to Drill via the Drill Shell \(SQLLine\)](#) on page 4841

SQLLine is a JDBC application that is packaged with Drill and serves as the Drill shell. When you issue queries from the SQLLine client, SQLLine passes the queries to the connected Drillbit (Drill node).

[Using the Drill JDBC Driver with SQuirreL on page 4846](#)

You can use the Drill JDBC driver with SquirrelL to connect to Drill and query the data sources configured in Drill.

[Java Sample Code](#) on page 4849

To use the Drill JDBC driver in an application, you must include all of the JAR files from the ZIP archive in the classpath for the Java project.

Connecting to Drill via the Drill Shell (SQLLine)

SQLLine is a JDBC application that is packaged with Drill and serves as the Drill shell. When you issue queries from the SQLLine client, SQLLine passes the queries to the connected Drillbit (Drill node).

You can connect to Drill through Sqlline directly or through a connection-property file. To avoid exposing credentials, connect through the connection-property file.

A JDBC connection string supplies the connection information to a Drill node or ZooKeeper cluster. When you connect to a ZooKeeper cluster, ZooKeeper selects the Drillbit for SQLLine to connect to.

JDBC Connection String Example

Here is an example of a JDBC connection string that connects SQLLine to drillnode1:

```
jdbc:drill:drillbit=drillnode1:31010
```

The default port on a Drill node is 31010.

Connection Parameters

You can include SQLLine connection parameters in the connection string and run various shell commands, as described in [Configuring the Drill Shell](#).

In the following example, `-u` is the connection parameter for the JDBC connection string, `-n` is the parameter for the username, and `-p` is the parameter for the password:

```
/opt/mapr/drill/drill-<version>/bin/sqlline -u
"jdbc:drill:drillbit=drillnode1:31010" -n mapr -p mapr
```

Starting SQLLine

Start SQLLine from the Drill installation directory, as shown:

```
/opt/mapr/drill/drill-<version>/bin/sqlline -u
jdbc:drill:drillbit=drillnode1:31010
```

Configuration Options

You can also include configuration options, such as schema:

```
/opt/mapr/drill/drill-<version>/bin/sqlline -u "jdbc:drill:drillbit
drillnode1:31010;schema=dfs" -n <username> -p <password>
```

Schema

The schema is the name of a [storage plugin](#) configuration to use as the default for queries. If you indicate the schema in the connection URL, you do not have to run the `USE <schema>;` query to switch to the schema you want to use. All queries run against the schema indicated in the JDBC connection string.

Authentication

If authentication (Plain, MAPRSASL, or Kerberos) is enabled, include the `auth` option in the connection string. If Drill is installed on a cluster secured by default security, set `auth=MAPRSASL`.

For additional configuration options, refer to the *Driver Configuration Options* section in the [JDBC Installation and Configuration Guide](#).

Connecting to a Specific Drill Node

Indicate which Drill node you want SQLLine to connect to in the JDBC connection string by using the following JDBC connection string format:

```
jdbc:drill:drillbit=<host>:<port>
```

Note that properties are case-sensitive. The host is the DNS or IP address of the server (Drill node). By default, the driver connects to port 31010.

Example

The following example shows how to run SQLLine with the JDBC connection string and includes the username, password, and `auth` parameters to authenticate to the server with Plain authentication:

```
/opt/mapr/drill/drill-<version>/bin/
sqlline -u
"jdbc:drill:drillbit=<ip-address>:<por
```

```
t>;auth=PLAIN" -n <username> -p
<password>
```

If you installed Drill on a cluster with default security enabled, set the auth type to maprsasl:

```
/opt/mapr/drill/drill-<version>/bin/
sqlline -u
"jdbc:drill:drillbit=<ip-address>:<por
t>;auth=MAPRSASL"
```

Connecting to ZooKeeper

When you include the ZooKeeper nodes in the JDBC connection string, ZooKeeper selects an available Drill node for SQLLine to use.

Indicate the ZooKeeper cluster you want SQLLine to connect to in the JDBC connection string, using the following JDBC connection string format:

```
jdbc:drill:zk=<zk-server-list>/drill/<clustername>
```

The zk-server-list is a comma-separated list of the ZooKeeper nodes in the cluster. The clustername is the unique name of the Drillbit cluster that you want to connect to.

IMPORTANT: You can locate the name of the Drillbit cluster in /opt/mapr/drill/drill-<version>/conf/drill-distrib.conf. The default name of the Drillbit cluster is drillbits1. The name is set by the cluster-id property. If you have multiple Drill clusters, you might want to override the Drillbit cluster name in drill-override.conf. However, first [back-up your storage plugin configurations](#), as they might reset to the defaults when you change the cluster name. Restart Drill after you edit drill-override.conf.

Note that properties are case-sensitive. The host is the DNS or IP address of the server (ZooKeeper node).

Example

The following example shows you how to configure the JDBC connection string to connect SQLLine to the ZooKeeper cluster:

```
/opt/mapr/drill/drill-<version>/bin/
sqlline
jdbc:drill:zk=<node-ip>:<port>,<node-i
p>:<port>,<node-ip>:<port>/drill/
drillbits1;auth=PLAIN
```

NOTE: The default port for ZooKeeper nodes in a Data Fabric cluster is 5181.

If you installed Drill on a secure cluster, set the auth type to maprsasl:

```
/opt/mapr/drill/drill-<version>/bin/
sqlline
jdbc:drill:zk=<node-ip>:<port>,<node-i
p>:<port>,<node-ip>:<port>/drill/
drillbits1;auth=MAPRSASL
```

Using a Connection-Property File with SQLLine

If you use a connection-property file, make sure you restrict user permission on the file to only those users you want to have access.

Complete the following steps to create a connection-property file and connect to Drill:

1. Create a connection-property file named `login.properties` with the following information:

```
url:<jdbc-connection-url>
user:<username>
password:<password>

//Example
cat login.properties
url:jdbc:drill:schema=dfs;drillbit=drill-lab-node01
user:drilluser
password:letsdrill
```

2. To connect to Drill, run SQLLine, as shown:

```
sqlline <sqlline args> <path/to/login.properties file>
```

The following examples show you how to connect to Drill through the connection-property file and how to verify that log in details are safe:

Example 1: Connecting to Drill via the connection-property file

```
sqlline login.properties

Java HotSpot(TM) 64-Bit Server VM
warning: ignoring option
MaxPermSize=512M; support was removed
in 8.0
apache drill 1.16.0
"drill baby drill"
0: jdbc:drill:schema=dfs> !list
1 active connection:
#0 open
jdbc:drill:schema=dfs;drillbit=drill-l
ab-node01
0: jdbc:drill:schema=dfs>!q
```

Example 2 : Submitting a query when connecting to Drill via the connection-property file

```
sqlline -q "SELECT version FROM
sys.version" login.properties
Java HotSpot(TM) 64-Bit Server VM
warning: ignoring option
MaxPermSize=512M; support was removed
in 8.0
apache drill 1.16.0
"the only truly happy people are
children, the creative minority and
drill users"
0: jdbc:drill:schema=dfs> select
version from sys.version
. . . . . > +-----+
| version |
+-----+
| 1.16.0  |
+-----+
1 row selected (0.295 seconds)
```

```
0: jdbc:drill:schema=dfs> Closing:
org.apache.drill.jdbc.impl.DrillConnec
tionImpl
$
```

Example 3: Use the properties command to connect to Drill via the connection-property file

```
Run sqlline from /opt/mapr/drill/
drill-<version>/bin sqlline

Java HotSpot(TM) 64-Bit Server VM
warning: ignoring option
MaxPermSize=512M; support was removed
in 8.0
apache drill 1.16.0
"a little sql for your nosql"

sqlline> !properties /home/drilluser/
login.properties
0: jdbc:drill:schema=dfs>
0: jdbc:drill:schema=dfs> !list
1 active connection:
 #0 open
jdbc:drill:schema=dfs;drillbit=drill-1
ab-node01
0: jdbc:drill:schema=dfs>
```

Example 4: Verify that Login Details are Safe

You can verify sqlline process information to confirm login details are not exposed to other users.

```
ps -ef | grep sqlline
drilluser      18938 21924 99 14:14
pts/0          00:00:03 /opt/
jdk1.8.0_141/bin/
java -XX:MaxPermSize=512M -Djava.secur
ity.auth.login.config=/opt/mapr/conf/
mapr.login.conf \
-Dzookeeper.sasl.client=false -Dhadoop
.login=simple -Dlog.path=/opt/mapr/
drill/drill-1.10.0/logs/
sqlline.log -Dlog.query.path=/opt/
mapr/drill/drill-1.16.0/logs/
sqlline_queries.json \
-cp /opt/mapr/drill/drill-1.10.0/
conf:/opt/mapr/drill/drill-1.16.0/
jars/*:/opt/mapr/drill/drill-1.16.0/
jars/ext/*:/opt/mapr/drill/
drill-1.16.0/jars/3rdparty/*:/opt/
mapr/drill/drill-1.16.0/jars/classb/*
sqlline.SqlLine -d
org.apache.drill.jdbc.Driver --maxWidt
h=10000 --color=true login.properties
drilluser      20119 1691 0 14:14
pts/1          00:00:00 grep sqlline
```

How to Protect the Password

Use the !connect command to mask and protect the password, as shown in the following example:

```
sqlline> !connect
jdbc:drill:drillbit=ip-10-0-0-33.eu-west-2.compute.internal:31010
```

```
Enter username for
jdbc:drill:drillbit=ip-10-0-0-33.eu-west-2.compute.internal:31010: alice
Enter password for
jdbc:drill:drillbit=ip-10-0-0-33.eu-west-2.compute.internal:31010: *****
```

Start|Stop the Drill Service

You can start|stop|restart the Drillbit service on one or more nodes by using the Control System or the following command:

```
maprccli node services -name drill-bits -action start|restart|stop -nodes
<node host names separated by a space>
```

Use the host name if possible. Using host names instead of IP addresses is a best practice.

Drill Log Files

You can access the Drill log files in `/opt/mapr/drill/drill-<version>/logs/drillbit.log`.

Using the Drill JDBC Driver with SquirrelL

You can use the Drill JDBC driver with SquirrelL to connect to Drill and query the data sources configured in Drill.

To use the Drill JDBC Driver with SquirrelL, verify that your system meets the prerequisites and then download and configure the driver.

Prerequisites

Verify that the system meets the following prerequisites:

- Java Runtime Environment (JRE), version 7.0 or later, installed on each machine where you plan to use the JDBC driver.
- Drill installed in distributed mode on one or multiple nodes in a cluster with data sources configured. See [Connecting Drill to Data Sources](#).
- Verify that the system can resolve the hostnames of the ZooKeeper nodes of the Drill cluster. You can do this by configuring DNS for all of the systems. Alternatively, you can edit the hosts file to include the hostnames and IP addresses of all the ZooKeeper nodes used with the Drill cluster.
 - For Windows, create the entry in the `%WINDIR%\system32\drivers\etc\hosts`.
 - For Linux and Mac, create the entry in `/etc/hosts`.

Example: `127.0.1.1 mapdemo`

Downloading and Configuring the Driver

This topic provides instructions for downloading and configuring the Drill JDBC driver for SquirrelL.

About this task

When you configure the driver, you define the driver and create an alias. The alias is a specific instance of the driver configuration. SquirrelL uses the driver definition and alias to connect to Drill so you can access data sources that you have registered with Drill. When you create the alias, you provide a connection URL that includes the name of the Drill directory stored in ZooKeeper and the cluster ID. The URL has the following format:

```
jdbc:drill:zk=<zookeeper_quorum>/<drill_directory_in_zookeeper>/<cluster_ID>
```

The following example shows a URL for Drill installed on a single node:

```
jdbc:drill:zk=10.10.100.56:5181/drill/demo_mapr_com-drillbits
jdbc:drill:zk=10.10.100.24:2181/drill/drillbits1
```

The following example shows a URL for Drill installed in distributed mode with a connection to a ZooKeeper quorum:

```
jdbc:drill:zk=10.10.100.30:5181,10.10.100.31:5181,10.10.100.32:5181/drill/
drillbits1
```

NOTE:

- The ZooKeeper port is 2181. In a Data Fabric cluster, the ZooKeeper port is 5181.
- The Drill directory stored in ZooKeeper is /drill.
- The Drill default cluster ID is drillbits1. To determine the cluster ID, check the following file:

```
<drill-installation>/conf/drill-override.conf
```

For example:

```
... drill.exec: { cluster-id: "docs41cluster-drillbits", zk.connect:
"centos23.lab:5181,centos28.lab:5181,centos29.lab:5181" } ...
```

To use the Drill JDBC driver with SquirrelL, complete the following steps:

Procedure

1. [Download the latest Drill JDBC Driver](#) and then unzip the file. The Drill JDBC Driver JAR files must exist in a directory on your machine before you can configure the driver in the SquirrelL client.
2. *If using the Data Fabric-SASL or Plain authentication mechanism*, add the Drill JDBC JAR files and /opt/mapr/lib/* to Squirrel's classpath, as shown in the following example when the path to the driver is C:\driver\MapRDrillJDBC41-1.5.6.1012:

```
-cp
"%SQUIRREL_CP%;C:\driver\MapRDrillJDBC41-1.5.6.1012\*;C:\opt\mapr\lib\*"
```

NOTE: The driver JAR files should appear before /opt/mapr/lib/* in the classpath.

3. Define the driver.
 - a) Open the SquirrelL client.
 - b) In the SquirrelL toolbar, select **Drivers > New Driver**. The Add Driver dialog appears.
 - c) Enter the following information:
 - **Name** - Name for the Drill JDBC Driver
 - **Example URL** - jdbc:drill:zk=<zookeeper_quorum>
Example: jdbc:drill:zk=maprdemo:5181

- **Website URL** - jdbc:drill:zk=<zookeeper_quorum>

Example: jdbc:drill:zk=maprdemo:5181

Example: jdbc:drill:zk=10.10.100.113:5181,10.10.100.115:5181

- d) Select **Extra Class Path**, and click **Add**.
 - e) Navigate to the directory that contains the JDBC JAR files.
 - f) Select all of the files in the directory, and click **Choose**.
 - g) In the Class Name drop-down field, select the driver class. For driver version 1.6.6.1009 and earlier, select **com.mapr.drill.jdbc41.Driver** or type **com.mapr.drill.jdbc41.Driver** in the field if the option does not appear. For driver version 1.6.7.1010, select **com.mapr.drill.jdbc.Driver** or type **com.mapr.drill.jdbc.Driver** in the field if the option does not appear.
 - h) Click **Ok**. The Squirrel client displays a message stating that the driver registration is successful, and you can see the driver in the Drivers panel.
4. Create a database alias.
- a) Select the **Aliases** tab.
 - b) In the Squirrel toolbar, select **Aliases > New Alias**. The Add Alias dialog box appears.
 - c) Enter the following information and click **Ok**.
 - **Alias Name** - A unique name for the Drill JDBC Driver alias
 - **Driver** - Select the Drill JDBC Driver
 - **URL** - Enter the connection URL with the name of the Drill directory stored in ZooKeeper and the cluster ID.
 - **User Name** - admin
 - **Password** - admin

The *Connect to:* dialog appears.
 - d) Click **Connect**. Squirrel displays a message stating that the connection is successful.
 - e) Click **Ok**. Squirrel is connected to Drill through the Drill JDBC driver. You can run your queries.

Running a Drill Query from Squirrel

Query sample data in Drill to verify that the Squirrel client is successfully connected to the cluster through the Drill JDBC driver.

About this task

Run a test query on sample data to test the Drill connection.

To query sample data with Squirrel, complete the following steps:

Procedure

1. Click the **SQL** tab.
2. Enter the following query in the query box: `SELECT * FROM cp.`employee.json`;`
3. Press **Ctrl+Enter** to run the query. The query results display.

Results

You have successfully run a Drill query from the SquirrelL client!

Java Sample Code

To use the Drill JDBC driver in an application, you must include all of the JAR files from the ZIP archive in the classpath for the Java project.

1. You can download JDBC driver or, starting from EEP-9.3.2, you can retrieve a compatible JDBC driver directly from a cluster with the `mapr-drill-internal` package installed. You can find the driver in the following directory:

```
$DRILL_HOME/jars/jdbc-driver/drill-jdbc-all-<drill-version>.jar
```

The following Java code shows how to use the JDBC API to:

- Register the driver for Drill
- Establish a connection to a Drill server (MAPRSASL secure cluster)
- Query demo data set from Drill classpath default examples (`cp.`employee.json``)
- Parse a result set
- Handle exceptions.

```
import java.sql.*;

public class DrillJDBCExample {
    private static final String JDBC_DRIVER =
"org.apache.drill.jdbc.Driver";
    private static final String CONNECTION_URL =
"jdbc:drill:drillbit=127.0.0.1:31010;auth=MAPRSASL";

    public static void main(String[] args) {
        try {
            // Load the JDBC driver
            Class.forName(JDBC_DRIVER);

            // Establish a connection
            try (Connection con =
DriverManager.getConnection(CONNECTION_URL);
                Statement stmt = con.createStatement();
                ResultSet rs = stmt.executeQuery("SELECT employee_id,
full_name, first_name, last_name, salary FROM cp.`employee.json` LIMIT
20")) {

                System.out.printf("%20s%20s%20s%20s%20s\r\n",
"employee_id", "full_name", "first_name", "last_name", "salary");

                while (rs.next()) {
                    System.out.printf("%20s%20s%20s%20s%20s\r\n",
                        rs.getString("employee_id"),
                        rs.getString("full_name"),
                        rs.getString("first_name"),
                        rs.getString("last_name"),
                        rs.getString("salary"));
                }
            } catch (Exception e) {
                System.err.println("Error: " + e.getMessage());
            }
        }
    }
}
```

```
}
}
```

NOTE: The `Class.forName(JDBC_DRIVER)` statement is not necessary for Java 6 and later versions, as the JDBC driver is automatically loaded when the `DriverManager.getConnection` method is called.

2. Compile the application using command:

```
javac DrillJDBCExample.java
```

3. Run the application to using the command:

```
java -cp /opt/mapr/drill/drill-1.21.2/jars/jdbc-driver/
drill-jdbc-all-1.21.2.100-eep-932-SNAPSHOT.jar:. DrillJDBCExample
```

Example of output

```
$ java -cp /opt/mapr/drill/drill-1.21.2/jars/jdbc-driver/
drill-jdbc-all-1.21.2.100-eep-932-SNAPSHOT.jar:. DrillJDBCExample

Drill ODBC Driver

HPE Data Fabric provides a Drill ODBC driver that you can download and use on all platforms to connect BI tools, such as Tableau, to Drill.

Use the version of the driver that correlates with the version of the installed Drill server. Although older versions of the driver may be able to connect to an upgraded version of Drill, the older drivers do not include all the server features available in the newer drivers.

The following table provides links to the download locations for the Drill ODBC drivers that correlate with each of the Drill versions listed:

IMPORTANT: To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see [Using the HPE Data Fabric Token-Authenticated Internet Repository](#) on page 153.

Drill Version	ODBC Version
1.16.0.100 - 1.20.3.100	1.5.1.1002
1.16.0, 1.16.1.0	1.3.22.1055
1.15.0	1.3.22.1055
1.14.0	1.3.22.1055
1.13.0	1.3.16.1049
1.12.0	1.3.15.1048
1.11.0	1.3.15.1046
1.10.0	1.3.8.1030

For information on Drill ODBC driver, see [Drill ODBC Driver](#).

Table

Authentication types	Direct Connection	ZooKeeper Connection
MapR-SASL	+ (64-bit Drill ODBC driver only)	-
PLAIN	+	-
KERBEROS	+	-
NO AUTH	+	+

With ZooKeeper authentication disabled, you can pick any authentication types (listed in the preceding table) to pass authentication against Drillbit. To manage Zookeeper authentication, use `zookeeper.sessionRequireClientSASLAuth`, `enforce.auth.enabled`, and `enforce.auth.schemes`. See ZooKeeper Documentation: [ZooKeeper: Because Coordinating Distributed Systems is a Zoo](#) for more information.

Using MapR-SASL for Authentication on Windows

Drill is automatically configured with default security when you install Drill 1.11 and later on a secure (version 6.x or later) cluster configured with the [default security](#). To successfully connect to Drill from a Windows ODBC client, the Data Fabric client must be installed and a `mapr` user ticket must exist on the Windows client in the `%TEMP%` directory or in the location specified by the `$MAPR_TICKETFILE_LOCATION` environment variable.

The ODBC driver locates user tickets for the current Windows user in the default ticket location, `%TEMP%`, or in the location specified by the environment variable, `$MAPR_TICKETFILE_LOCATION`. See [Tickets](#) and [Generating a MapR User Ticket](#) for more information.

You can either copy a user ticket that was generated on the cluster into the default location (`%TEMP%`), or you can run the `mapr login` command to generate the ticket on the Windows client.

If you copy a user ticket that was generated on the cluster, you must copy the `mapr-clusters.conf` file to the client machine. Copy the file from `/opt/mapr/conf/mapr-clusters.conf` to `C:/opt/mapr/conf/mapr-clusters.conf` on the client machine. Verify that the cluster to which the client is connecting is listed as the first entry in the `mapr-clusters.conf` file. Also, if the cluster is secure, verify that `secure=true` for the cluster entry in the file.

NOTE: The ODBC user must be the same as the Windows user that created the ticket.

Example

If you want to connect to Drill as the `mapr` user, you must create a ticket for the `mapr` user, as shown:

```
$ maprlogin password -user mapr
[Password for user 'mapr' at cluster 'Cluster1':]
```

The credentials for the `mapr` user in `Cluster1` are written to `/tmp/maprticket_1000`.

Next, place the ticket in the `%TEMP%` directory on the Windows client. For example, the default location for a Windows 10 user named Tabetha Stephens is shown:

```
'C:\Users\TABETH~1\AppData\Local\Temp\maprticket_Tabetha Stephens'
```

To override this location, set the `"MAPR_TICKETFILE_LOCATION"` global variable for the Windows user.

NOTE: Using the `MAPR_TICKETFILE_LOCATION` is recommended because the `%TEMP%` directory differs between Windows versions. You may also want to set the `MAPR_TICKETFILE_LOCATION` per user on the operating system to prevent all users from using the same user ticket on the client.

Driver Limitations

When using MapR-SASL with JDBC or ODBC drivers, there is no way to specify the target cluster name as part of the connection parameters. MapR-SASL reads the first entry in the `/opt/mapr/conf/mapr-clusters.conf` file and assumes it is the target cluster name.

For example, if the `mapr-clusters.conf` file has an entry for `'cluster1'` followed by an entry for `'cluster2'` and you want to connect to a node in `'cluster2'`, authentication fails. As a workaround, manually switch the order of entries in the `mapr-clusters.conf` file.

Driver Issues

The following errors can occur in RHEL 8, Rocky Linux 8, CentOS, and CentOS 8 due to an incompatibility between the bundled `libcrypto.so` ODBC driver library and the `libk5crypto.so` system library:

- `SQLDriverConnect = [iODBC][Driver Manager]/lib64/libk5crypto.so.3: \nundefined symbol: EVP_KDF_ctrl, version OPENSSL_1_1_1b (0) SQLSTATE=00000`
- `[unixODBC][Driver Manager]Can't open lib '/opt/mapr/drill/lib/64/libdrillodbc_sb64.so':\nfile not found`

Use either of the following methods to resolve the issue:

- Remove the bundled crypto library from the ODBC driver RPATH:

```
rm /opt/mapr/drill/lib/64/ThirdParty/libcrypto.so.1.1
```

- Make the dynamic linker load the system version of the crypto library with a higher priority than the bundled ODBC library. How this is done depends on the version of the dynamic linker.

How to Connect to Drill from Tableau on Windows

Provides instructions for using the Drill ODBC driver to connect Tableau on a Windows PC to Drill on an HPE Data Fabric node.

The instructions in this document were created using the following environment:

- PC running Windows 10 (64-bit system)
- Secure HPE Data Fabric 7.0.0 node (non-FIPS compliant)
- Drill 1.16.1.400 (EEP 8.1.0) installed on the HPE Data Fabric node
- Tableau version 2021.4.3 installed on the Windows PC

This document walks you through the steps required to:

- Download, install, and configure JDK 11
- Install the Data Fabric 7.0.0 client on a Windows 64-bit computer (Required to access Drill on the HPE Data Fabric) node
- Download and install the Drill ODBC driver (v1.3.22.1055) and configure the DSN
- Connect to Tableau (version 2021.4.3)
- Run a couple of queries to test the Tableau connection to Drill

Download and Install JDK 11

Complete the steps in the following sections to download and install JDK 11. Once you have it installed, set `JAVA_HOME`.

Download JDK 11

Downloading JDK requires an Oracle account. You can create an account before completing the steps listed in this section, or you can follow the steps listed, create your account in step 4 and then repeat steps 1 - 4 again, but instead of creating an account in step 4, entering your credentials.

To download JDK 11:

1. Go to <https://www.oracle.com/java/technologies/downloads/#java11>.
2. Scroll down to the **Java SE Development Kit 11.0.14** section and select the **Windows** tab.
3. Click **jdk-11.0.14_windows-x64_bin.exe** to download.
4. Accept the license agreement and click the download button. An Oracle account log in window appears. Enter your Oracle account credentials or click Create Account. If you enter your credentials and click Sign in... the download begins. If you create an account, complete steps 1 - 4 again to get the download after you create your account.

Install JDK 11

Click the downloaded `jdk-11.0.14_windows-x64_bin.exe` file. An installation wizard walks you through the installation process. Once installation completes, set the `JAVA_HOME` environment variable.

Set JAVA_HOME

To set `JAVA_HOME`:

1. In Windows, go to **View advanced system settings**. The System Properties window appears.
2. Select the **Advanced** tab.
3. Click **Environment Variables**.
4. Click **New**. The New System Variable window opens.
5. Enter `JAVA_HOME` as the variable name.
6. Enter `C:\PROGRA~1\Java\jdk-11.0.14` as the Variable value. If your JDK version is different, replace `jdk-11.0.14` with your version. Currently, Data Fabric 7.0.0 supports JDK 11.
7. In the System Variables section, select **Path** and then click **Edit**.
8. Verify that `%JAVA_HOME%\bin` is listed. If it is not listed, add it.
9. Click **OK** on each system screen until they all close. To verify that JDK was installed, open the Windows command prompt and run:

```
C:\Users\myname> java -version

//The system should return the following:
java version "11.0.14" 2022-01-18 LTS
Java(TM) SE Runtime Environment 18.9 (build 11.0.14+8-LTS-263)
Java HotSpot(TM) 64-Bit Server VM 18.9 (build 11.0.14+8-LTS-263, mixed mode)
```

Install the HPE Data Fabric Client on Windows

The HPE Data Fabric client is required to connect to the HPE Data Fabric cluster node running Drill. Note that when you download the client, the client package name is `mapr-client`.

To install the Data Fabric client on your Windows PC, download the client package for Windows and then complete the installation and configuration steps.

1. Create an `\opt\mapr` directory on your `c:` drive. You can do this using Windows Explorer, or you can open the Windows command prompt and type the following in the prompt:

```
mkdir c:\opt\mapr
```

2. Add the MAPR_HOME environment variable:

- a. In Windows, go to **View advanced system settings**. The System Properties window appears.
- b. Select the **Advanced** tab.
- c. Click **Environment Variables**.
- d. Click **New**. The New System Variable window opens.
- e. Enter MAPR_HOME as the variable name.
- f. Enter MAPR_HOME=C:\opt\mapr as the variable value.
- g. Click **OK**.
- h. In the System Variables section, double-click the **Path** variable. The Edit Environment Variable window opens.
- i. Verify that the following variables appear in the list:

```
%JAVA_HOME%\bin
%MAPR_HOME%\bin
```

- j. Click **New** and add %MAPR_HOME%\hadoop\hadoop-2.7.6\bin. You should now see the following environment variables in the list:

```
%JAVA_HOME%\bin
%MAPR_HOME%\bin
%MAPR_HOME%\hadoop\hadoop-2.7.6\bin
```

- k. Click **OK** on all screens to exit the environment variables windows.

3. Download the mapr-client package:

- a. Go to https://package.ezmeral.hpe.com/releases/v7.0.0/windows/<package_name>.
- b. Click on the mapr-client-7.0.0.0 Windows client package to download it.
- c. Right-click on the downloaded file and select **Extract All...**. Extract all to the C:\opt\mapr\ folder. Once extracted, you should see several files and folders listed in C:\opt\mapr, as shown in the following image:

4. If your Windows command prompt is open, close it and reopen it.
5. Go to the C:/opt/mapr directory by running the following command:

```
cd /opt/mapr
```

6. Run the configuration script. These instructions assume that the cluster you will be connecting to is secure. To run the configuration script, run the following command in the Windows command prompt:

```
server\configure.bat -N <cluster_name> -c -secure -C  
<node-ip-address>:7222
```

**NOTE:**

- -N specifies the cluster name.

TIP: If you do not know the cluster name, you can use Putty or a similar tool to access the node in the cluster that you want to connect the client to and get the cluster name from the `mapr-clusters.conf` file. When you access the node, go to `/opt/mapr/conf` and then cat the `mapr-clusters.conf` file, for example:

```
cd /opt/mapr/conf
cat mapr-clusters.conf

//You will see something like the following example returned
where myCluster is the cluster name:
myCluster secure=true 10.10.10.279:7222
```

- -c (lowercase) specifies a client configuration.
 - -secure indicates connecting to a secure cluster.
 - -C (uppercase) specifies the CLDB node(s).
 - 7222 is the default port for the CLDB node.
7. Copy the `ssl_truststore` and `ssl-client.xml` files from the `/opt/mapr/conf` directory on the cluster node to the `C:\opt\mapr\conf` directory on the Windows client. Using a tool like WinSCP is useful for this.
 8. On the Windows PC, run the following command to create a ticket:

NOTE: When you connect to Drill, you will authenticate to Drill with the username and password that you use in this step.

```
maprlogin password -user <DataFabricUserName>
```

This command creates a ticket for `<DataFabricUserName>`, usually found in:

```
C:\Users\<WindowsUserName>\AppData\Local\Temp\maprticket_<WindowsUserName>
```

9. In Windows, create a new environment variable named `MAPR_TICKETFILE_LOCATION` and set the variable value to `C:\Users\<WindowsUserName>\AppData\Local\Temp\maprticket_<WindowsUserName>`.
10. From the Windows command prompt, run a hadoop command to validate that the client is connected to the cluster node:
 - a. Go to the `hadoop-2.7.6` directory:

```
cd /opt/mapr/hadoop/hadoop-2.7.6
```

- b. Run the following hadoop command:

```
hadoop fs -ls /
```

//Note that the / indicates a directory path.

The command should return results similar to the following:

```
Found 5 items
drwxr-xr-x - uid_5000 gid_5000 4 2022-02-07 06:22 /apps
drwxr-xr-x - uid_5000 gid_5000 0 2022-02-07 06:10 /opt
drwxrwxrwx - uid_5000 gid_5000 0 2022-02-07 06:08 /tmp
drwxr-xr-x - uid_5000 gid_5000 1 2022-02-07 06:11 /user
drwxr-xr-x - uid_5000 gid_5000 2 2022-02-07 06:11 /var
```

Download the Drill ODBC Driver

To download the Drill ODBC driver:

1. Go to https://package.ezmeral.hpe.com/tools/MapR-ODBC/MapR_Drill/MapRDrill_odbc_v1.3.22.1055/.
2. Click MapRDrill 1.3 64-bit.msi to download the Windows 64-bit driver.
3. Click the downloaded file and follow the setup wizard to install the driver.
4. If you received a license file through email, copy the license file into the \lib sub-folder of the installation folder. You must have administrator privileges to change the contents of this folder.

Configure the DSN

To create a Data Source Name on Windows:

1. In Windows, go to **ODBC Data Sources**. The ODBC Data Source Administrator (64-bit) window opens.
2. In the ODBC Data Source Administrator, click the **Drivers** tab and then scroll down to verify that the **MapR Drill ODBC Driver** appears in the list of ODBC drivers installed on your system.
3. click the **System DSN** tab.
4. Click **Add**.
5. In the Create New Data Source dialog box, select **MapR Drill ODBC Driver** and then click **Finish**. The Drill ODBC Driver DSN Setup dialog box opens.
6. In the Data Source Name field, type a name for your DSN.
7. To connect to the Drill node, select **Direct to Drillbit** and then type the IP address or host name of the Drill server in the field beside the Direct to Drillbit option and the port on which the Drill server is listening. The port is typically 31010, for example: 10.10.10.279:31010.
8. In the Authentication Type drop-down, select **MapRSASL**.
9. To test the connection, click **Test**. A successful connection returns a success message. If the connection fails, verify that the settings in the MapR Drill ODBC Driver DSN Setup dialog box are correct.
10. Click **OK** to exit the windows.

Connect Tableau to the Drill ODBC Driver (DSN)

Note that version 2021.4.3 of Tableau was used to create these instructions.

To connect Tableau to the Drill ODBC driver (DSN):

1. Open Tableau.
2. Select **Connect To Server > More > Other Database (ODBC)**. The Other Database (ODBC) window opens.
3. In the DSN drop-down, select the DSN you created (when you completed the steps in the *Configure the DSN* section).
4. Click **Connect**.
5. Enter your credentials to authenticate and then click **Sign in....** Use the same credentials you used when you created a ticket for the mapr-client.
6. To verify that Tableau is connected to the Drill node, run a couple of test queries:
 - a. Double-click **New Custom SQL**.
 - b. In the Edit Custom SQL box, enter the following query and then click **Preview Results...**:

```
SELECT * FROM sys.drillbits
```

The query should return results similar to the following:

View Data: Custom SQL Query+

1 row

current	hostname	state	version	control_port	data_port	http_port	user_port
True	m2-mapreng-vm...	ONLINE	1.16.1.400-eep...	31,011	31,012	8,047	31,010

- c. Close the View Data: Custom SQL Query + box.
- d. In the Edit Custom SQL box, enter the following query and then click **Preview Results...**:

```
SELECT * FROM cp.`employee.json` LIMIT 3
```

This query runs against a sample file (`employee.json`) included in Drill's classpath. The query should return the following results:

View Data: Custom SQL Query+

3 rows

birth_date	education_level	first_name	full_name	gender	hire_date	last_name	management_role	marital_status	position_title	department_id	employee_id	position_id	salary	store_id	supervisor_id
1961-09-26	Graduate Degree	Shen	Shen Nowner	F	1994-12-01 00:...	Nowner	Senior Managem...	S	President	1	1	1	80,000.00	0	0
1915-07-03	Graduate Degree	Derrick	Derrick Whelphy	M	1994-12-01 00:...	Whelphy	Senior Managem...	M	VP Country Man...	1	2	2	40,000.00	0	1
1969-06-20	Graduate Degree	Michael	Michael Spence	M	1998-01-01 00:...	Spence	Senior Managem...	S	VP Country Man...	1	4	2	40,000.00	0	1

Drill Configuration Files

The Drill installation includes configuration files with start-up options that you can modify prior to starting Drill.

The configuration files reside in a **HOCON** configuration file format, which is a hybrid between a properties file and a JSON file. The files have a nested relationship and a hierarchical structure, where one file overrides another. You can locate the files in the `/opt/mapr/drill/drill-<version>/conf` directory.

The configuration files are listed below in their hierarchical order. The `drill-distrib.conf` file overrides the `drill-module.conf` file, and the `drill-override.conf` file overrides the `drill-distrib.conf` file.

- `drill-override.conf`

- drill-distrib.conf
- drill-module.conf

Environment variables are also overridden in the same way, in the order listed below:

- drill-env.sh (or explicitly defined in environment)
- distrib-env.sh
- drill-config.sh

The following table lists the configuration files with their descriptions:

File Name	Description	Default Configuration with Secure Installation
drill-distrib.conf	Contains distribution-specific configurations for Drill. Automatically updated by configure.sh when you configure the cluster.	<ul style="list-style-type: none"> • Enables authentication, impersonation, and encryption with HPE Data Fabric-SASL as the default mechanism. • Enables TLS for the HTTPS channel.  NOTE: By default, HTTPS uses the SSL certificate provided by the cluster installation; however, an administrator can specify a certificate in a keystore. <ul style="list-style-type: none"> • Enables the inbound impersonation policy for administrators to impersonate any other user.
distrib-env.sh	Contains distribution-specific defaults for various environment variables.	<ul style="list-style-type: none"> • Enables authentication between the Drillbits and ZooKeeper. • Configures the location of the default security configuration file, mapr.login.conf, used by Drill.
drill-env.sh	The drill-env.sh file contains the cluster administrator-specific environment variables that can differ from the defaults. You can modify this file to override the default values of system properties defined in the distrib-env.sh file or to define a new system property. For example, you can configure the amount of heap and direct memory allocated to Drill. See Configuring Drill Memory on page 4732.	Empty upon installation.
drill-override.conf	Use the drill-override.conf file to override the default values obtained from drill-module.conf and drill-distrib.conf. A cluster administrator can update this file to configure a Drillbit as required (different from default installation)	When you first install Drill, drill-override.conf contains ZooKeeper and Drillbit configuration information; however, after you run configure.sh -R, the entries are removed and the file does not contain any configurations.

Mask Sensitive Data in Query Logs and Profiles

Starting in Drill 1.20.2 (EEP 9.0.0 installed on Core 7.1.0), you can define a set of rules in a JSON file to mask sensitive data in Drill query logs and query profiles.

Masking Data in Query Logs

Drill includes the following Logback encoder and layout classes that enable you to configure Drill logs such that data in the final message is masked:

- `org.apache.drill.logback.MaskingPatternEncoder`
- `org.apache.drill.logback.MaskingPatternLayout`

The Drill encoder and layout provide the same functions as the following encoder and layout:

- `ch.qos.logback.classic.encoder.PatternLayoutEncoder`
- `ch.qos.logback.classic.PatternLayout`

The following examples demonstrate how to configure the Drill masking pattern encoder and layout in the `/opt/mapr/drill/drill-<version>/conf/logback.xml` file:

Masking Pattern Encoder Example

```
<configuration>
  <appender name="STDOUT"
    class="ch.qos.logback.core.ConsoleAppender">
    <encoder
      class="org.apache.drill.logback.MaskingPatternEncoder">
        <rulesConfig>$
{pathToJsonConfig}</rulesConfig>
        <pattern>%d{HH:mm:ss.SSS}
[%thread] %-5level %logger{36} -
%msg%n</pattern>
      </encoder>
    </appender>

  <root>
    <level value="error" />
    <appender-ref ref="STDOUT" />
  </root>
</configuration>
```

Masking Pattern Layout Example

```
<configuration>
  <appender name="STDOUT"
    class="ch.qos.logback.core.ConsoleAppender">
    <encoder
      class="ch.qos.logback.core.encoder.LayoutWrappingEncoder">
        <layout
          class="org.apache.drill.logback.MaskingPatternLayout">
            <rulesConfig>$
{pathToJsonConfig}</rulesConfig>
            <pattern>%d{HH:mm:ss.SSS}
[%thread] %-5level %logger{36} -
%msg%n</pattern>
          </layout>
        </encoder>
      </appender>
```

```

</appender>

<root>
  <level value="error" />
  <appender-ref ref="STDOUT" />
</root>
</configuration>

```

Both examples include the `rulesConfig` parameter. The `rulesConfig` parameter is where you include the path to a JSON file that defines the masking rules. Enter the absolute path to the JSON file; do not use a relative path.

For information about how to define masking rules in a JSON file, see [Configuring Masking Rules in a JSON File](#) on page 4862.

Masking Data in Query Profiles

You can define rules that mask the following information in query profiles:

- Query plan text
- Queries
- Errors
- Verbose errors

To mask data in query profiles, define the masking rules in a JSON file and then set the `drill.exec.query_profile.masking_rules.config_path` parameter in the `/opt/mapr/drill/drill-<version>/conf/drill-override.conf` or `/opt/mapr/drill/drill-<version>/conf/drill-distrib.conf` file to point to the JSON file.

For information about how to define masking rules in a JSON file, see [Configuring Masking Rules in a JSON File](#) on page 4862. For more information about Drill configuration files, see [Drill Configuration Files](#) on page 4859.

Configuring Masking Rules in a JSON File

The JSON file that defines the masking rules must include an array of objects with the following fields:

- `search`
- `replace`
- `description`

Use these fields to define the rules, as shown in the following examples:

```

[
  {
    "search": "([\\w\\d]+\\.)(com)",
    "replace": "secret.domain.com",
    "description": "Mask domain names"
  },
  {
    "search": "MagicCompany",
    "replace": "TopSecretCompany",
    "description": "Mask company name"
  }
]

```

The following table describes each of the fields that define the masking rules:

Field	Required	Description	Default
search	Yes	Defines the string or regex pattern to mask. If entering a regex pattern, use the correct escaping . Drill does not apply the rule when this field is empty, null, or omitted.	-
replace	No	Defines the string that you want to mask the search string or regex pattern with. If you want to remove the search string or regex pattern, use "" to leave the space empty.	""
description	No	An optional field used to describe the search and replace rules. The description is not returned in the logs or query profiles.	Empty

Monitoring Drill Metrics

You can monitor Drill metrics and logs using the Kibana and Grafana interfaces that are available through [Data Fabric Monitoring](#). The [Kibana](#) interface is a log monitoring tool. The [Grafana](#) interface is a metrics monitoring tool where you can view system-level metrics for Drill.

Drill uses JMX ([Java Management Extensions](#)) to monitor queries at runtime. JMX provides the architecture to dynamically manage and monitor applications. JMX collects Drill system-level metrics that you can access through Grafana or through the Metrics page in the [Drill Web Console](#).

You must install a specific set of services on cluster nodes to use the Kibana and Grafana monitoring tools. You can install the services using the [Data Fabric installer](#), or you can [install these services manually](#). If you install the monitoring services in a cluster running Drill, you must restart Drill in order for Drill to communicate with JMX. However, if you install Drill after the monitoring services are installed, you must run the `configure.sh` command and restart the Drillbit service in order for the monitoring services to recognize that a new application is running in the cluster.

The following table lists the predefined Drill system-level metrics that you can view in Grafana:

Metric	Description
mapr.drill allocator_root_used	The amount of memory used by the internal memory allocator. Measured in bytes.
mapr.drill queries_running	The number of queries running for which the Drillbit is the foreman.
mapr.drill queries_completed	The number of completed, cancelled, or failed queries for which the Drillbit was the foreman.
mapr.drill fragments_running	The number of query fragments currently running in the Drillbit.
mapr.drill allocator_root_peak	The peak amount of memory used by the internal memory allocator. Measured in bytes.
mapr.drill heap_used	The amount of heap memory used by the JVM. Measured in bytes.
mapr.drill non_heap_used	The amount of non-heap memory used by the JVM. Measured in bytes.
mapr.drill count	The number of live daemon and non-daemon threads.
mapr.drill fd_usage	The ratio of used file descriptors to total file descriptors.
mapr.drill runnable_count	The number of threads executing in the JVM. This metric is useful for debugging Drill issues.
mapr.drill waiting_count	The number of threads waiting to be executed. This may occur when a thread waits on another thread to perform an action before proceeding. This metric is useful for debugging Drill issues.

mapr.drill.blocked_count	The number of blocked threads waiting for a monitor lock. This metric is useful for debugging Drill issues.
--------------------------	---

Optimizing Queries with Indexes

HPE Data Fabric Database provides a highly scalable key-value database platform on which you can run SQL queries using Drill. As a part of the 6.0 release, HPE Data Fabric Database natively supports indexes on secondary fields in JSON tables.

NOTE: HPE Data Fabric Database does not support indexes on binary tables.

An index is a special table that stores a subset of document fields from a JSON table. The primary field in a JSON table is the `_id` field (unique key field). By default, HPE Data Fabric Database sorts the JSON table by the `_id` field. All other fields in the JSON table are secondary fields. You can create indexes on the secondary fields in a JSON table to eliminate full tables scans and significantly improve query performance. See [HPE Data Fabric Database as a Document Database](#) and [Secondary Index Concepts](#) for more information.

Benefits of Indexes

Well-designed indexes can optimize access to data stored in HPE Data Fabric Database JSON tables and improve performance for high read operations, fast integrated analytics, and complex operational analytics. See [Secondary Indexes](#) for more information about the benefits of indexes.

Types of Queries that Benefit from Indexes

Indexes primarily benefit queries with filters in the WHERE clause and queries with an ORDER BY clause for sorting, as described in the following table:

Query Type	Description
Equality	Equality queries contain equality conditions, such as <code>a=1</code> and can also include IN. See Equality Queries .
Range	Range queries contain range conditions, such as <code><=</code> , <code>>=</code> , and the LIKE pattern matching condition. See Range Queries . NOTE: The LIKE operator only works on fields that have varchar data types. To use the LIKE operator in queries, use the CAST function to explicitly cast fields to varchar. To use indexes for such queries, create indexes on the cast expressions, as explained in Using Casts in Secondary Indexes .
ORDER BY	ORDER BY queries specify a sort order. If the ordering and sorting of the index key list match the ordering specified in a query, the optimizer in Drill does not have to sort the data after the index scan. See ORDER BY Queries .
Multi-index	Multi-index queries contain conditions on multiple fields. Drill can scan multiple indexes and use the intersection of the matching documents to optimize these queries. Multi-index queries are an alternative to using composite key indexes . See Multi-Index Queries .

Drill can create index plans for queries with and without filters in the WHERE clause. For example, Drill can create an index plan for an ORDER BY query that does not have filters.

Drill 1.12 and later also supports the following types of queries without filters :

- GROUP BY

- JOIN
- DISTINCT

See [Index Planning in Drill](#) for more information.

Types of Indexes Supported by HPE Data Fabric Database

HPE Data Fabric Database supports several types of indexes on JSON tables including simple, composite, hashed, covering, and indexes with the CAST function.

NOTE: HPE Data Fabric Database enforces certain [restrictions](#) on indexes, such as a limit of 32 KB on the collective size of all indexed keys for each index. See [Restrictions on Secondary Indexes](#) for a full list of restrictions and [Data Types Supported for Secondary Indexes](#).

The following table lists the supported index types with brief descriptions and links to topics that provide more information:

Index Type	Description
Simple	Simple indexes are indexes with a single indexed field (or key). See Simple Indexes .
Composite	Composite indexes are indexes that have more than one indexed field (or key). See Composite Indexes .
Hashed	Hashed indexes are indexes that distribute keys across logical partitions to avoid the creation of hot spots when HPE Data Fabric Database updates the index with new keys from the JSON table. See Hashed Indexes .
Covering	A covering index is an index that allows HPE Data Fabric Database to process a query using only the secondary indexes. HPE Data Fabric Database does not have to read data in the JSON table. See Covering Indexes on page 770.
Indexes with the CAST function	Indexes with the CAST function convert the indexed field to the data type specified by the CAST function and store the results. See Using Casts in Secondary Indexes .

Steps Required to Use Indexes

To use the index functionality with Drill, complete the following steps:

1. Install the latest version of the required Data Fabric software on the cluster. See [Preparing Clusters for Querying using Secondary Indexes on JSON Tables](#) and [Installing Drill](#).
2. Evaluate your queries and design indexes that support the queries. See [Understanding the Secondary Index Workflow](#) and [Designing Secondary Indexes](#).
3. Create indexes on JSON tables in HPE Data Fabric Database. See [Adding Secondary Indexes on JSON Tables](#) and [Managing Secondary Indexes](#).

NOTE: The user that creates indexes on a JSON table must have created the table or have the `indexperm` permission in addition to `readAce` on the volume and `lookupdir` on directories in the table path. If you do not have these permissions, consult with your system administrator.

4. Issue queries.
5. Verify that Drill uses the available indexes. See [Determining Index Use](#) and [Troubleshooting Indexes](#).

Additional Information

- To see how Drill selects a query plan, see [Selection and Execution of Secondary Indexes](#).
- To learn about the index planning and execution configuration options available in Drill, see [Index Planning and Execution Configuration Options](#).
- For information about index architecture, see [Implementation of Secondary Indexes](#).

Index Planning in Drill

Index planning reduces the I/O operation costs associated with full table scans. If an index is available, Drill can use the index to improve query performance.

Drill can use indexes to create query plans for queries that filter on indexed fields or fields included in an index. Fields in COUNT, COUNT DISTINCT, JOIN, GROUP BY, and ORDER BY also determine index use. Drill can create index-based query plans for queries with and without filters (WHERE clause).

NOTE: In Drill 1.11 and earlier, if a query does not have a filter, the query must have an ORDER BY clause.

Drill can create index plans for queries with an ORDER BY clause whether or not the query contains a filter, as shown in the following example:

```
SELECT L_LINENUMBER FROM lineitem ORDER BY L_LINENUMBER;
```

NOTE: In this example, L_LINENUMBER is an indexed field in the index selected for the query plan.

In Drill 1.12 and later, Drill can also create index-based query plans for the following types of queries when they do not have filters (WHERE clause):

- **GROUP BY** queries, as shown in the following example where L_COMMITDate is an indexed field in the index selected for the query plan:

```
SELECT L_COMMITDate FROM lineitem GROUP BY L_COMMITDate;
```

- **JOIN** queries, as shown in the following example where L_ORDERKEY and O_ORDERKEY are indexed fields and L_LINESTATUS is an included field in the index selected for the query plan:

```
SELECT L.L_LINESTATUS FROM lineitem L, orders O WHERE  
L.L_ORDERKEY=O.O_ORDERKEY;
```

NOTE: If the planner picks two indexes, one for lineitem and one for orders, a sort merge join is used instead of a hash join.

- Queries with **DISTINCT** projections, as shown in the following examples where L_LINENUMBER is an indexed field in the index selected for the query plan:

```
SELECT DISTINCT L_LINENUMBER FROM lineitem;  
SELECT COUNT(DISTINCT L_LINENUMBER) FROM lineitem;
```

Drill can use indexes for queries that GROUP BY or ORDER BY the leading fields in an index. Drill does not use indexes for queries that GROUP BY or ORDER BY the trailing or included fields in an index.

When a query contains GROUP BY and ORDER BY operations on the leading indexed column, Drill can use the sort order of the index to create index-based query plans that use streaming aggregates and merge joins to improve query performance.

You can run the [EXPLAIN PLAN FOR](#) command with a query to see the query plan that Drill creates. See [Covering and Non-Covering Queries](#) for more information about index planning in Drill.

Index Planning and Execution Configuration Options

The 1.11 release of Drill introduces options that affect how Drill uses indexes when planning and executing queries. You can set the query planning and execution options, at the system or session level, using the ALTER SYSTEM|SESSION SET commands, as shown:

```
ALTER SYSTEM SET `planner.enable_index_planning` = true
ALTER SESSION SET `planner.enable_index_planning` = false
```

Options set at the session level only apply to queries that you run during the current Drill connection.

Options set at the system level affect the entire system and persist between restarts. Session level settings override system level settings. Typically, you set the options at the session level unless you want the setting to persist across all sessions.

The following table lists the index planning and execution options that you can enable, disable, or modify:

NOTE: The planning option names are prefaced by planner, for example `planner.enable_index_planning`. The execution options are prefaced by exec, for example `exec.query.rowkeyjoin_batchsize`.

Option	Description	Default Value	Possible Values
<code>planner.enable_index_planning</code>	Enables or disables index planning	true	true false
<code>planner.index_force_sort_noncovering</code>	Forces Drill to sort for non-covering indexes. If the query has an ORDER-BY on index columns and a non-covering index is chosen, by default Drill leverages the sortedness of the index columns and does not sort. Fast changing primary table data may produce a partial sort. This option forces a sort within Drill. NOTE: (Drill 1.11 only) You must enable this option for Drill to return the results of a non-covering query in sorted order.	false	true false
<code>planner.enable_rowkeyjoin_conversion</code>	Introduced in Drill 1.13. Drill can push down the rowkey filter to HPE Data Fabric Database during runtime. For a query to qualify for runtime filter pushdown, the join condition must filter on a rowkey. A rowkey is the value of the <code>_id</code> field in a JSON document, for example: <pre>SELECT t.mscIdentities FROM dfs.root.`/user/mapr/MixTable` t WHERE t.row_key IN (SELECT max(convert_fromutf8(i.KeyA.ENTRY_KEY)) FROM dfs.root.`/user/mapr/TableIMSI` i WHERE i.row_key='460021050005636')</pre> Drill evaluates the results of the subquery at runtime. The subquery yields a list of rowkeys from the TableIMSI table. Drill pushes down the list of rowkeys to HPE Data Fabric Database. HPE Data Fabric Database uses the rowkeys to locate the corresponding documents in the MixTable table and sends the results to Drill. NOTE: Currently, Drill does not support runtime filters for queries with equality conditions. The query planner in Drill converts an equality condition to a left join. As a workaround, use the IN operator instead of the equality (=) operator for queries in which you want Drill to push down the rowkey filter to HPE Data Fabric Database. Drill does not perform runtime filter pushdown for queries that filter on rowkeys in small fact tables when the rowcount is generated from the right side of the join.	true	true false

planner.rowkeyjoin_conversion_selectivity_threshold	Introduced in Drill 1.13. Sets the selectivity (as a percentage) under which Drill uses a rowkey join for eligible queries.	0.01	Range : 0.0-1.0
planner.rowkeyjoin_conversion_using_hashjoin	Introduced in Drill 1.13. When enabled, Drill uses the hash join operator instead of a rowkey join.	false	true false
planner.index.covering_selectivity_threshold	For covering indexes, this option specifies the filter selectivity that corresponds to the leading prefix of the index below which the index is considered for planning. For example, for the filter 'a > 10 AND b < 20' if an index has indexed fields (a, b, c) and the combined selectivity of the above condition is less than the threshold, the index is considered for the query plan.	0.75	0 - 1.0
planner.index.noncovering_selectivity_threshold	For non-covering indexes, this option specifies the filter selectivity that corresponds to the leading prefix of the index below which the index is considered for planning.	0.025	0 - 1.0
planner.index.max_chosen_indexes_per_table	The maximum number of "chosen" indexes for a table after index costing and ranking.	5	0 - 100
planner.index.rowkeyjoin_cost_factor	The cost factor that provides some control over the I/O cost for non-covering indexes when the rowkey join back to the primary table causes random I/O from the primary table.	0.1	0 - max_double
planner.enable_statistics	Enable or disable statistics for the filter conditions on indexed columns.	true	true false
exec.query.rowkeyjoin_batchsize	For batch GET operations, this option specifies the batch size in terms of the number of rowkeys. Used for non-covering index plans when doing joins back to primary table.	128	0 - Long. MAX_VALUE
exec.query.progress.update	Enable or disable updating transient query state in ZooKeeper. Disable this option for short running operational queries. When disabled, you do not see the query state , such as STARTING and RUNNING in the Drill Web Console.	true	true false
exec.udf.use_dynamic	Enable or disable using dynamic UDFs for the queries. Disable this option for operational queries. When disabled, you cannot use dynamic UDFs for queries.	true	true false
exec.query_profile.save	Enable or disable saving query profiles for the queries. Disable this option for operational queries. When disabled, Drill does not save query profiles and they are not available for analysis or debugging.	true	true false
planner.use_simple_optimizer	Enable or disable using simple optimizer for queries. Simple optimizer applies fewer rules to reduce planning time and is meant to be used only for simple operational queries that use limit, sort, and filter. This optimizer applies rules for leveraging secondary indexes when index planning is enabled. Enable this option for operational queries.	false	true false

Index Planning and Execution Options for Operational Queries

The following table lists the index planning and execution options for operational queries that you can enable, disable, or modify:

Option	Description	Default Value	Possible Values
--------	-------------	---------------	-----------------

exec.query.progress.update	Enable or disable updating transient query state in ZooKeeper. Disable this option for short running operational queries. When disabled, you do not see the query state, such as STARTING and RUNNING in the Drill Web Console.	true	true false
exec.udf.use_dynamic	Enable or disable using dynamic UDFs for the queries. Disable this option for operational queries. When disabled, you cannot use dynamic UDFs for queries.	true	true false
exec.query_profile.save	Enable or disable saving query profiles for the queries. Disable this option for operational queries. When disabled, Drill does not save query profiles and they are not available for analysis or debugging.	true	true false
planner.use_simple_optimizer	Enable or disable using simple optimizer for queries. Simple optimizer applies fewer rules to reduce planning time and is meant to be used only for simple operational queries that use limit, sort, and filter. This optimizer applies rules for leveraging secondary indexes when index planning is enabled. Enable this option for operational queries.	false	true false

Covering and Non-Covering Queries

Drill uses a cost-based approach to determine an optimal query plan. When queries are eligible for index planning, the queries are either covering or non-covering.

For covering queries, only the index is needed to process the query. Drill creates an index-based query plan that includes an index scan. Covering queries avoid the overhead of fetching data from the primary table.

For non-covering queries, the index only contains a subset of the data required to process the query. Drill creates a query plan that includes an index scan and a join back to the primary table. In some scenarios, a full table scan is more cost efficient than an index scan and Drill will not create an index plan.

NOTE: (Drill 1.11 only) You must enable the `planner.index.force_sort_noncovering` option for Drill to return the results of a non-covering query in sorted order. See [Index Planning and Execution Configuration Options](#)

Indexes for covering and non-covering queries can contain indexed fields, or a combination of indexed and included fields. HPE Data Fabric Database stores included fields in the index. Each field added to the index increases the storage requirement for the index. As the storage size increases, the cost of reading the index also increases. Likewise, for the cost of adding and updating documents. Consider the impact on storage and updates when adding included fields to an index.

- For information about how Drill selects a query plan, see [Selection and Execution of Secondary Indexes](#).
- For information about the types of queries that qualify for index-based plans, see [Queries that Benefit from Secondary Indexes](#).
- For index concepts, see [Secondary Index Concepts](#).

Covering and Non-Covering Query Examples

A query can be covering or non-covering based on the fields referenced in the query and the fields on which an index is created and/or includes.

The following query examples use an index, *l_comp_1*, created on a table, *lineitem*.

The *l_comp_1* index was created using the `maprcli table index add` command, as shown:

```
maprcli table index add -path /drill/testdata/tpch/sf1/
maprdb/json/range/lineitem -index l_comp_1 -indexedfields
L_LINENUMBER,L_ORDERKEY -includedfields L_LINESTATUS,L_QUANTITY
```

Covering Query Example

The following query references the *L_LINESTATUS*, *L_QUANTITY*, *L_LINENUMBER*, and *L_ORDERKEY* fields in the *lineitem* table:

```
SELECT L_LINESTATUS, L_QUANTITY FROM lineitem WHERE L_LINENUMBER = 1 AND
L_ORDERKEY BETWEEN 40 AND 75;
```

Because the *l_comp_1* index includes all fields referenced in the query, Drill creates a query plan that uses the index only.

Running the [EXPLAIN PLAN FOR](#) command with the query shows that Drill created a query plan that only uses the index to process the query:

```
EXPLAIN PLAN FOR SELECT L_LINESTATUS, L_QUANTITY FROM lineitem WHERE
L_LINENUMBER = 1 AND L_ORDERKEY BETWEEN 40 AND 75;

00-00      Screen
00-01      Project(L_LINESTATUS=[0], L_QUANTITY=[1])
00-02      Scan(table=[[si, tpch_sf1_maprdb_range,
lineitem]], groupscan=[JsonTableGroupScan [ScanSpec=JsonScanSpec
[tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/json/range/lineitem,
condition=((L_LINENUMBER = {"$numberLong":1}) and (L_ORDERKEY
>= {"$numberLong":40})) and (L_ORDERKEY <= {"$numberLong":75}))],
indexName=l_comp_1], columns=[`L_LINESTATUS`, `L_QUANTITY`]]])
```

Reading the query plan, you can see that the plan includes an index scan, as indicated by *groupscan=[JsonTableGroupScan* and *indexName*. Drill and HPE Data Fabric Database can process this query using only the index.

Non-Covering Query Example

The following query references the *L_RETURNFLAG*, *L_LINESTATUS*, *L_QUANTITY*, *L_LINENUMBER*, and *L_ORDERKEY* fields in the *lineitem* table:

```
SELECT L_RETURNFLAG, L_LINESTATUS, L_QUANTITY FROM lineitem WHERE
L_LINENUMBER = 1 AND L_ORDERKEY BETWEEN 40 AND 75;
```

Because the *l_comp_1* index does not include the *L_RETURNFLAG* field, Drill creates a query plan that uses the index, but also includes a join on the primary table.

Running the EXPLAIN PLAN FOR command with the query shows that Drill includes an index scan and a table scan:

```
EXPLAIN PLAN FOR SELECT L_RETURNFLAG, L_LINESTATUS, L_QUANTITY FROM
lineitem WHERE L_LINENUMBER = 1 AND L_ORDERKEY BETWEEN 40 AND 75;

00-00      Screen
00-01      Project(L_RETURNFLAG=[0], L_LINESTATUS=[1], L_QUANTITY=[2])
00-02      Project(L_RETURNFLAG=[2], L_LINESTATUS=[3], L_QUANTITY=[4])
00-03      Project(L_LINENUMBER=[0], L_ORDERKEY=[1],
L_RETURNFLAG=[2], L_LINESTATUS=[3], L_QUANTITY=[4])
00-04      RowKeyJoin(condition=[=($5, $6)], joinType=[inner])
00-06      Scan(table=[[si, tpch_sf1_maprdb_range,
lineitem]], groupscan=[RestrictedJsonTableGroupScan [ScanSpec=JsonScanSpec
[tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/json/range/lineitem,
condition=((L_LINENUMBER = {"$numberLong":1}) and (L_ORDERKEY
>= {"$numberLong":40})) and (L_ORDERKEY <= {"$numberLong":75}))],
columns=[`L_LINENUMBER`, `L_ORDERKEY`, `L_RETURNFLAG`, `L_LINESTATUS`,
`L_QUANTITY`, `_id`], rowcount=60012.150000000001]])
00-05      Scan(table=[[si, tpch_sf1_maprdb_range,
lineitem]], groupscan=[JsonTableGroupScan [ScanSpec=JsonScanSpec
[tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/json/range/lineitem,
condition=((L_LINENUMBER = {"$numberLong":1}) and (L_ORDERKEY
>= {"$numberLong":40})) and (L_ORDERKEY <= {"$numberLong":75}))],
indexName=l_comp_1], columns=[`_id`]])
```

Reading the query plan, you can see that the plan includes an index scan, as indicated by the *groupscan=[JsonTableGroupScan* and *indexName*, and also a scan on the primary table, as indicated by the *groupscan=[RestrictedJsonTableGroupScan* and the *RowKeyJoin*. To process this query, Drill and HPE Data Fabric Database can use the index, but HPE Data Fabric Database must also use the rowkey to perform a join on the primary table to fetch data in the L_RETURNFLAG field.

If this query ran on a regular basis, you could remove the *l_comp_1* index and create a new index that includes all fields referenced in the query, including the L_RETURNFLAG field, to improve query performance. However, running a query only once or a few times may not justify the overhead of removing the old index and creating a new index.

Non-Hashed and Hashed Indexes

You can create non-hashed and hashed indexes for queries on JSON tables in HPE Data Fabric Database.

Non-hashed indexes support conditional queries with an ORDER BY clause because HPE Data Fabric Database sorts the data in non-hashed indexes. When processing ORDER BY queries, Drill does not have to perform sort operations on the data.

Hashed indexes support the same conditional queries as non-hashed indexes, but they do not have a guaranteed sort order. Hashed indexes enable HPE Data Fabric Database to evenly distribute new writes on an index across logical partitions to avoid hot spotting. Drill must perform a sort for ORDER BY queries that use hashed indexes. Sorting the data can increase the CPU costs and negatively impact performance. See [Hashed Indexes](#) for additional information.

If you notice performance issues with ORDER BY queries that use hashed indexes, review the query plans to see if the plans include sort and merge operations. If this is the case, create non-hashed indexes to support the queries and achieve the best performance.

Examples of Hashed and Non-Hashed Index Plans for an ORDER BY Query

The examples here show the difference between a hashed and non-hashed index plan for the following query on the lineitem table that contains the [ORDER BY](#) clause:

```
SELECT L_LINESTATUS, L_QUANTITY FROM lineitem WHERE L_LINENUMBER = 1 AND
L_ORDERKEY BETWEEN 40 AND 75 ORDER BY L_LINENUMBER;
```

Hashed Index Plan Example

A hashed index, `L_hash_comp_1`, was created using the `maprccli table index add` command on a table, `lineitem`, as shown:

```
maprccli table index add -path /drill/testdata/tpch/sf1/
maprdb/json/hash/lineitem -index L_hash_comp_1 -indexedfields
L_LINENUMBER,L_ORDERKEY -includedfields L_LINESTATUS,L_QUANTITY -hashed true
```

Running the example query with the [EXPLAIN PLAN FOR](#) command shows that Drill produces an index plan with sort and merge operations to process the query when using the hashed index, as follows:

```
EXPLAIN PLAN FOR SELECT L_LINESTATUS, L_QUANTITY FROM lineitem WHERE
L_LINENUMBER = 1 AND L_ORDERKEY BETWEEN 40 AND 75 ORDER BY L_LINENUMBER;

00-00    Screen
00-01      Project(L_LINESTATUS=[0], L_QUANTITY=[1])
00-02      SingleMergeExchange(sort0=[2])
01-01        SelectionVectorRemover
01-02        Sort(sort0=[2], dir0=[ASC])
01-03          Project(L_LINESTATUS=[2], L_QUANTITY=[3],
L_LINENUMBER=[0])
01-04          Scan(table=[[si, tpch_sf1_maprdb_hash,
lineitem]], groupscan=[JsonTableGroupScan [ScanSpec=JsonScanSpec
[tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/json/hash/lineitem,
condition=((L_LINENUMBER = {"$numberLong":1}) and (L_ORDERKEY
>= {"$numberLong":40})) and (L_ORDERKEY <= {"$numberLong":75})),
indexName=L_hash_comp_1, columns=[`L_LINENUMBER`, `L_ORDERKEY`,
`L_LINESTATUS`, `L_QUANTITY`]]])
```

Reading the query plan, you can see that Drill uses the hashed index in the plan, as indicated by `indexName=L_hash_comp_1`. To process the query, HPE Data Fabric Database can use the index, but Drill must sort and merge the data, as indicated by the `Sort` and `SingleMergeExchange` operations in the query plan.

Using the hashed index plan for this ORDER BY query requires additional processing and negatively impacts performance.

Non-Hashed Index Plan Example

A non-hashed index, `L_comp_1`, was created using the `maprccli table index add` command on a table, `lineitem`, as shown:

```
maprccli table index add -path /drill/testdata/tpch/sf1/
maprdb/json/range/lineitem -index L_comp_1 -indexedfields
L_LINENUMBER,L_ORDERKEY -includedfields L_LINESTATUS,L_QUANTITY
```

Running the example query with the [EXPLAIN PLAN FOR](#) command shows that Drill produces an index plan without the additional sort and merge operations when using the non-hashed index to process the query, as follows:

```
EXPLAIN PLAN FOR SELECT L_LINESTATUS, L_QUANTITY FROM lineitem WHERE
L_LINENUMBER = 1 AND L_ORDERKEY BETWEEN 40 AND 75 ORDER BY L_LINENUMBER;

00-00    Screen
00-01      Project(L_LINESTATUS=[0], L_QUANTITY=[1])
00-02      Project(L_LINESTATUS=[2], L_QUANTITY=[3], L_LINENUMBER=[0])
00-03      Scan(table=[[si, tpch_sf1_maprdb_range,
lineitem]], groupscan=[JsonTableGroupScan [ScanSpec=JsonScanSpec
[tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/json/range/lineitem,
condition=((L_LINENUMBER = {"$numberLong":1}) and (L_ORDERKEY
>= {"$numberLong":40})) and (L_ORDERKEY <= {"$numberLong":75})),
```

```
indexName=l_comp_1], columns=[`L_LINENUMBER`, `L_ORDERKEY`, `L_LINESTATUS`,
`L_QUANTITY`]]])
```

Reading the query plan, you can see that Drill uses the non-hashed index plan, as indicated by *indexName=l_comp_1*. To process the query, HPE Data Fabric Database uses the index and Drill does not have to perform sort and merge operations on the data, as indicated by the absence of the Sort and SingleMergeExchange operations in the query plan. HPE Data Fabric Database sorted the data in the index when the index was created.

Writing Drill Queries that Leverage Indexes on Array Fields

Starting in EEP 6.0, the query planner in Drill can leverage indexes created on Data Fabric Database JSON document fields with array data types, such as "NUMBERS": [1, 2, 3, 4, 5] and "ADDRESSES": [{"CITY" : "SAN JOSE"}, {"CITY" : "PALO ALTO"}].

See [JSON Document Data Types](#) and [Data Types and Secondary Index Fields](#) for definitions and detailed examples.

If you want the query planner in Drill to leverage an index created on a field with an array data type, you must write the Drill query such that it includes specific SQL syntax, as shown in bold in the following example:

```
SELECT NAME, PHONE
FROM CUSTOMERS
WHERE _id IN ( SELECT _id
                FROM ( SELECT _id, FLATTEN(ADDRESSES) as f
                    FROM CUSTOMERS) as t
                WHERE t.f.CITY = 'SAN JOSE' and t.f.STATE = 'CA')
;
```

The specific SQL syntax indicates (to the query planner in Drill) that the query is eligible for an index-based query plan.

The [FLATTEN function](#) separates elements in an array into individual records in a table. For example, if an array consists of five elements, FLATTEN separates each element into a single row, creating a table with five rows.

The IN operator prevents Drill from returning duplicate rows. For example, when an array is flattened into a table, duplicate values may exist for a particular _id (rowkey). Using IN prevents Drill from returning rows with duplicate values.

Example

Suppose a JSON primary table named CUSTOMERS exists in HPE Data Fabric Database with the following data:

```
{ "_id": "001",
  "NAME": "ALICE",
  "PHONE": "408-555-1212",
  "ADDRESSES": [{"CITY" : "SAN JOSE" , "ZIPCODE" : 95124, "STATE" :
"CA", "UNITS" : [{"UNIT_NO":555, "FLOOR": 5}, {"UNIT_NO":777, "FLOOR":
7}]}], {"CITY" : "PALO ALTO", "ZIPCODE" : 94020, "STATE" : "CA",
"UNITS" : [{"UNIT_NO":555, "FLOOR": 5}, {"UNIT_NO":777, "FLOOR": 7}]}],
{"CITY" : "SANTA CLARA", "ZIPCODE" : 95050, "STATE" : "CA", "UNITS" :
[{"UNIT_NO":555, "FLOOR": 5}, {"UNIT_NO":777, "FLOOR": 7}]}],
  "QTY": [11, 25, 16, 2, 10, 39, 5, 8, 7, 11]
}
{ "_id": "002",
  "NAME": "BOB",
  "PHONE": "408-555-1313",
  "ADDRESSES": [{"CITY" : "SAN JOSE" , "ZIPCODE" : 95132, "STATE" :
"CA", "UNITS" : [{"UNIT_NO":838, "FLOOR": 8}, {"UNIT_NO":888, "FLOOR":
8}]}], {"CITY" : "SAN JOSE", "ZIPCODE" : 95127, "STATE" : "CA", "UNITS" :
```

```
[{"UNIT_NO":555, "FLOOR": 5}, {"UNIT_NO":777, "FLOOR": 7}]], {"CITY" :
"SAN RAMON", "ZIPCODE" : 94582, "STATE" : "CA", "UNITS" : [{"UNIT_NO":123,
"FLOOR": 1}, {"UNIT_NO":124, "FLOOR": 1}]]},
"QTY": [2, 8, 1, 4, 3, 10, 2, 23]
}
{ "_id": "003",
"NAME": "CHRIS",
"PHONE": "408-555-1414",
"ADDRESSES": [{"CITY" : "MOUNTAIN VIEW", "ZIPCODE" : 94043, "STATE" :
"CA", "UNITS" : [{"UNIT_NO":922, "FLOOR": 9}, {"UNIT_NO":958, "FLOOR":
9}]], {"CITY" : "PALO ALTO", "ZIPCODE" : 94020, "STATE" : "CA", "UNITS" :
[{"UNIT_NO":666, "FLOOR": 6}, {"UNIT_NO":728, "FLOOR": 7}]], {"CITY" :
"SUNNYVALE", "ZIPCODE" : 94086, "STATE" : "CA", "UNITS" : [{"UNIT_NO":226,
"FLOOR": 2}, {"UNIT_NO":333, "FLOOR": 3}]]},
"QTY": [56, 19, 45, 25, 4, 77, 110, 3, 2, 1]
}
```

 **NOTE:** The QTY field is an array. The ADDRESSES field is an array of maps.

The following query on the CUSTOMERS table returns the result of flattening the “ADDRESSES” array field into a column aliased as “f” where each element in the array is flattened into individual rows:

 **NOTE:** In the results, notice that Bob has two addresses where the “CITY” is “SAN JOSE”. Later in this example, you will see that using the IN operator prevents the query from returning duplicate rows.

```
SELECT NAME, PHONE, f FROM (SELECT NAME, PHONE, FLATTEN(ADDRESSES) AS f
FROM CUSTOMERS);
```

```
+-----+-----+-----+

{"FLOOR":7, "UNIT_NO":777}], "ZIPCODE":95127}
+-----+-----+-----+

```

Suppose a composite index exists on ADDRESSES[].CITY and ADDRESSES[].STATE with "NAME" as an included field. For the query planner to use the index, you must write the query using the specific SQL syntax that indicates that the query is eligible for an index-based query plan, as shown:

```

SELECT NAME, PHONE
FROM CUSTOMERS
WHERE _id IN ( SELECT _id
FROM ( SELECT _id, FLATTEN(ADDRESSES) as f
FROM CUSTOMERS) as t
WHERE t.f.CITY = 'SAN JOSE' and t.f.STATE = 'CA');

```

//Issuing this query against the data in the CUSTOMERS table returns the following results:

```

+-----+-----+-----+
| NAME | PHONE |
+-----+-----+-----+
| ALICE | 408-555-1212 |
| BOB | 408-555-1313 |
+-----+-----+-----+

```

 **NOTE:** Although Bob has two addresses where the "CITY" is "SAN JOSE", the query returns only one result. The IN operator prevents the query from returning duplicate rows.

The following list summarizes key points about this query:

- The innermost subquery projects on the `_id` field (rowkey) and includes the `FLATTEN` function to separate the array elements in the "ADDRESSES" field. The field "ADDRESSES" is flattened into a table aliased as "t", in a column aliased as "f".
- The query uses the `IN` operator to ensure that the results returned contain unique values only; no duplicates. `DISTINCT` on the subquery to the right of `IN` is implicit. The SQL query pattern indicates to the query planner that the query is eligible for an index-based query plan.
- The query projects on column "NAME" and "PHONE". "PHONE" requires a join back to the primary table on the `_id` field (rowkey) because it is not included in the composite index.
- The query planner recognizes that `t.f.CITY` references `t.ADDRESSES[].CITY` and `t.f.STATE` references `t.ADDRESSES[].STATE` and creates an index-based query plan.
- The index table in HPE Data Fabric Database is already flattened for the array field, "ADDRESSES". Flatten is not evaluated in Drill. Drill pushes the filter conditions on the array field into HPE Data Fabric Database.

Filter Conditions on Various Types of Array Fields

The following table shows examples of filter conditions on various types of array fields and includes the HPE Data Fabric Database notation for the array field with the filter condition, as well as the SQL syntax for writing queries against the array fields.

 **NOTE:** The queries in the table are written against the CUSTOMERS data used in the previous example.

Filter condition on ...	Example using HPE Data Fabric Database notation (not SQL notation)	SQL																																
Array of scalar values	QTY[] < 10	<pre>SELECT NAME, PHONE FROM CUSTOMERS WHERE _id IN (SELECT _id FROM (SELECT _id, FLATTEN(Q FROM CUSTOMERS) as t WHERE t.f<10);</pre> <p>This query returns the following results:</p> <table><tr><td>+</td><td>-----+</td><td>-----+</td><td>+</td></tr><tr><td> </td><td>NAME</td><td> </td><td>PHONE</td><td> </td></tr><tr><td>+</td><td>-----+</td><td>-----+</td><td>+</td></tr><tr><td> </td><td>ALICE</td><td> </td><td>408-555-1212</td><td> </td></tr><tr><td> </td><td>BOB</td><td> </td><td>408-555-1313</td><td> </td></tr><tr><td> </td><td>CHRIS</td><td> </td><td>408-555-1414</td><td> </td></tr><tr><td>+</td><td>-----+</td><td>-----+</td><td>+</td></tr></table>	+	-----+	-----+	+		NAME		PHONE		+	-----+	-----+	+		ALICE		408-555-1212			BOB		408-555-1313			CHRIS		408-555-1414		+	-----+	-----+	+

Performance Considerations

When writing queries that leverage indexes on array fields, consider the following points about performance:

- Query patterns that match those described previously in this document are pushed down to HPE Data Fabric Database. Drill does not evaluate the filter conditions, which adds considerable performance benefits even when the query planner does not select an index-based query plan.

- Deduplication on the `_id` is an extra operation (compared to regular, non-complex, indexes) that requires the overhead of hash aggregation.
- Try to avoid array columns in included fields within an index table, as they add a significant amount of storage overhead. However, this may result in the query planner selecting non-covering plans.
- Indexes with deeply nested array elements, such as `a[] . b[] . c[] . . . x . y`, can add to the HPE Data Fabric Database storage overhead and can potentially make Drill queries longer and more complex.

Limitations

Drill queries that leverage indexes on array fields have the following limitations:

- Only queries with patterns similar to those described previously in this document are eligible for index planning, assuming that the index is defined on an array field.
- The following conditions do not produce a covering index plan:
 - Pushdown conditions on indexed fields and included fields on same array element. For example, if an index has indexed fields `a[] . b` and included fields `a[] . c`, `elementAND(a[], b > 10, c > 20)` does not produce a covering index plan.
 - Pushdown conditions on scalar indexed fields and included fields containing an array element. For example, an index with indexed field `m` and included fields `a[] . b`, `m = 10 AND a[] . b > 20` does not produce a covering index plan.
- For included array fields, the element must be provided without the `[]` for the query planner to pick covering plans. For example, `a` and not `a[]`. Note that HPE Data Fabric Database considers both `a` and `a[]` syntaxes as equivalent for included fields.
- Index planning is disabled for queries with multi-level flattens and intermediate filters that reference multi-level flattens. A filter can reference the root level flatten, but not the intermediate flattens.

Determining Index Use

Evaluate the query plan to analyze query performance and determine if Drill uses indexes. You can view query plans in the Drill Web Console or through the command line using the `EXPLAIN` command. You can also disable the indexing option in Drill and compare an index-based plan to a full table scan plan.

Drill leverages indexes during the physical planning phase of the query. Drill estimates the cost of an index-based plan and a plan that includes a full table scan. See [Selection and Execution of Secondary Indexes](#) for information about how Drill selects a query plan. In cases where Drill does not select the index-based plan and instead selects a full table scan plan, you may want to remove the indexes to free up storage space and eliminate the overhead of the indexes.

The following example shows you how to determine if Drill selected an index-based plan for a query through the query profile in the Drill Web Console and the `EXPLAIN PLAN FOR` output.

Example

The subsequent sections assume that an index exists on a table named "lineitem." The index, `I_single_c_5`, is a single field index created on the `L_QUANTITY` field. The index also covers the `L_SUPPKEY`, `L_DISCOUNT`, `L_SHIPDate`, and `L_SHIPMODE` fields. If a query contains fields covered by the index, the query is a covering query. If a query contains fields not covered by the index, the query is non-covering and requires a lookup back into the primary table to retrieve data.

The following list summarizes the assumptions:

- **Table name:** `lineitem`
- **Index name:** `I_single_c_5`

- **Indexed field:** L_QUANTITY
- **Included fields:** L_SUPPKEY, L_DISCOUNT, L_SHIPDate, L_SHIPMODE

Query Profile

View the query plan on the **Profiles** tab in the Drill Web Console. See [Starting the Web Console](#). Select the query you want to evaluate and then select the **Physical Plan** tab. You can see the physical plan that Drill used to execute the query.

The following image shows the physical plan that Drill used to execute this simple equality query:

```
SELECT L_SHIPDate FROM lineitem WHERE L_QUANTITY = 5;
```

Query and Planning

Query Physical Plan Visualized Plan Edit Query

```
00-00 Screen : rowType = RecordType(ANY L_SHIPDate): rowcount = 10.0, cumulative cost = {609.0440673828125 rows, 1247.088134765625 cpu, 64.0 io, 0.0 network, 0.0 memory}, id = 24576
00-01 Project(L_SHIPDate=[0]) : rowType = RecordType(ANY L_SHIPDate): rowcount = 10.0, cumulative cost = {608.0440673828125 rows, 1246.088134765625 cpu, 64.0 io, 0.0 network, 0.0 memory}, id = 24575
00-02 SelectionVectorRemover : rowType = RecordType(ANY L_SHIPDate): rowcount = 10.0, cumulative cost = {608.0440673828125 rows, 1246.088134765625 cpu, 64.0 io, 0.0 network, 0.0 memory}, id = 24574
00-03 Limit(fetch=[10]) : rowType = RecordType(ANY L_SHIPDate): rowcount = 10.0, cumulative cost = {598.0440673828125 rows, 1236.088134765625 cpu, 64.0 io, 0.0 network, 0.0 memory}, id = 24573
00-04 Limit(fetch=[10]) : rowType = RecordType(ANY L_SHIPDate): rowcount = 10.0, cumulative cost = {588.0440673828125 rows, 1196.088134765625 cpu, 64.0 io, 0.0 network, 0.0 memory}, id = 24572
00-05 Project(L_SHIPDate=[1]) : rowType = RecordType(ANY L_SHIPDate): rowcount = 578.0440673828125, cumulative cost = {578.0440673828125 rows, 1156.088134765625 cpu, 64.0 io, 0.0 network, 0.0 memory}, id = 24571
00-06 Scan(groupscan=[JsonTableGroupScan [ScanSpec=JsonScanSpec [tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/json/lineitem, condition=(L_QUANTITY = {"$numberLong":5}), indexName=l_single_c_5, columns=[L_QUA
```

Query Profile

STATE: COMPLETED

FOREMAN: sid#11

TOTAL FRAGMENTS: 1

DURATION: 0.523 sec

PLANNING: 0.502 sec

QUEUED: Not Available

EXECUTION: 0.021 sec

In the plan, you can see that Drill scanned the index, l_single_c_5, instead of the primary table. The query was completely covered by the index because the index contains all fields referenced in the query and the query filtered on the indexed field.

EXPLAIN PLAN

Alternatively, you can issue the [EXPLAIN](#) command to see how Drill executes a query. To see the chosen physical execution plan for a query without running the query, issue the [EXPLAIN PLAN FOR](#) command. This command shows you if Drill plans to use the index when executing the query.

The following image shows the physical plan that Drill plans to use to execute this simple equality query:

```
EXPLAIN PLAN FOR SELECT L_SHIPDate FROM lineitem WHERE L_QUANTITY = 5 LIMIT 10;
+-----+-----+
| text | json |
+-----+-----+
| 00-00 Screen
00-01 Project(L_SHIPDate=[0])
00-02 SelectionVectorRemover
00-03 Limit(fetch=[10])
00-04 Limit(fetch=[10])
00-05 Project(L_SHIPDate=[1])
00-06 Scan(groupscan=[JsonTableGroupScan
[ScanSpec=JsonScanSpec [tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/
json/lineitem, condition=(L_QUANTITY = {"$numberLong":5}),
indexName=l_single_c_5], columns=[L_QUANTITY`, `L_SHIPDate`]]])
```

In the plan, you can see that Drill plans to use the index, `l_single_c_5`, instead of performing a full table scan. The query is completely covered by the index because the index contains all fields referenced in the query and the query filters on the indexed field.

Compare Plans

If you want to compare an index-based plan against a plan with a full table scan, disable the `planner.enable_index_planning` option in Drill, and run the `EXPLAIN PLAN FOR` command for the query. Running this command with the `planner.enable_index_planning` option disabled forces Drill to generate a plan that includes a full table scan. You can compare the full table scan plan against the index-based plan to compare the costs and resource consumption of each plan.

You can see in the following query, with the indexing feature turned on, Drill generated a plan using the index:

```
EXPLAIN PLAN FOR SELECT L_SHIPDate FROM lineitem WHERE L_QUANTITY = 5 LIMIT
10;
+-----+-----+
| text | json |
+-----+-----+
| 00-00      Screen
00-01      Project(L_SHIPDate=[0])
00-02      SelectionVectorRemover
00-03      Limit(fetch=[10])
00-04      Limit(fetch=[10])
00-05      Project(L_SHIPDate=[1])
00-06      Scan(groupscan=[JsonTableGroupScan
[ScanSpec=JsonScanSpec [tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/
json/lineitem, condition=(L_QUANTITY = {"$numberLong":5}),
indexName=l_single_c_5], columns=[`L_QUANTITY`, `L_SHIPDate`]]])
```

If you turn the option off, as shown:

```
ALTER SESSION SET planner.enable_index_planning = false
```

You can run the `EXPLAIN PLAN FOR` command again to see the plan with a full table scan included:

```
EXPLAIN PLAN FOR SELECT L_SHIPDate FROM lineitem WHERE L_QUANTITY = 5 LIMIT
10;
+-----+-----+
| text | json |
+-----+-----+
| 00-00      Screen
00-01      Project(L_SHIPDate=[0])
00-02      SelectionVectorRemover
00-03      Limit(fetch=[10])
00-04      UnionExchange
01-01      SelectionVectorRemover
01-02      Limit(fetch=[10])
01-03      Project(L_SHIPDate=[1])
01-04      Scan(groupscan=[JsonTableGroupScan
[ScanSpec=JsonScanSpec [tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/
json/lineitem, condition=(L_QUANTITY = {"$numberLong":5})],
columns=[`L_QUANTITY`, `L_SHIPDate`]]])
|
```

NOTE: To see the cost of each plan, go to the Drill Web Console and view the query profile for each `EXPLAIN PLAN FOR` command that you issue through the command line.

Drill Table Function

Explains Apache Drill's table functions (table-valued functions - TVFs).

Apache Drill supports table functions, also known as table-valued functions (TVFs). Functions return a table. You can use functions anywhere that you can use a table. Table functions behave similarly to views, but can take parameters.

Syntax

To invoke a table function, you must wrap it with the special `TABLE ( )` construct. This wrapper signals that the function returns a table rather than a scalar value:

```
table(table_function_name())
```

This construct is case-insensitive.

Drill table functions

Currently, Drill supports two types of table functions.

- Schema table function
- Format plugin table function

These functions are called using the target table name, but they define different parameters.

The function arguments are passed using the parameter names and the `=>` syntax:

```
table_name(parameter_name => some_value)
```

CAUTION: Function parameter names are case-sensitive.

Schema table function

A schema table function allows you to define a schema for an individual query. You can specify a path to the schema or provide the schema directly in the query. This is useful when the table's schema, which normally resides in the table's root folder, is located elsewhere, or when you want to reference an alternate schema or define the schema inline.

The schema table function works with tables from any data storage, but schema provisioning is [supported only for text files](#).

Starting with DEP version 10.0.0, schema provisioning is also supported for JSON MapR-DB tables. However, the schema is used only as a hint to resolve ambiguous column types, such as columns that contain only null values. Schema provisioning for JSON MapRDB tables is not a replacement for the CAST function. If you have a column stored as STRING and you want it to be INT – use the CAST function: [Data Type Conversion - Apache Drill](#).

The schema table function has one parameter: `schema`.

For more details about the schema provisioning feature and the schema table function syntax, see [Schema provisioning using a table function](#).

Parameters

- `schema` - accepts a string value of two kinds: `path` and `inline`.

The `path` value is used to specify a path to the table schema:

```
table_name(schema => 'path=`/path/to/the/schema`')
```

For example:

```
SELECT *
FROM TABLE(dfs.tmp.`myTable.csv`(schema => 'path=`/tmp/schemas/
myTableSchema`'))
```

The inline value is used to provide a schema directly in the query:

```
table_name(schema => 'inline=(column_name data_type [nullability] [format]
[default] [properties {prop='val', ...}]))')
```

For example:

```
SELECT *
FROM TABLE(dfs.tmp.`text_table`(
  schema => 'inline=(col1 date properties {`drill.format` =
`yyyy-MM-dd`})
  properties {`drill.strict` = `false`}'))
```

Format plugin table function

The format plugin table function allows you to override the format options from the file system storage plugin or replace the table's detected format with your own.

The format specified here takes precedence over the format automatically detected by Drill. If the defined format matches the format detected by Drill, the storage format options from the storage plugin are used as defaults and overridden by any parameters specified in the table function.

Parameters

- **type - required.** The file system table format. Valid values are the names of Drill format plugins. The values are case-sensitive and include: delta, spss, logregex, syslog, parquet, sequencefile, pcap, xml, iceberg, json, ltsv, text, maprdb, avro, image, sas, pcapng, streams, httpd, excel, pdf, shp, hdf5, msaccess.
- **dynamic parameters - optional.** Parameters that correspond to the Drill format plugin configuration variables, excluding extensions (which do not apply in this context).
- **schema - optional.** The value corresponds to the value for the same option in the schema table function.

Examples

Set extractHeader option for a csv file:

```
SELECT *
FROM TABLE(dfs.tmp.`users.csv`(type => 'text', extractHeader => true))
```

Set fieldDelimiter, extractHeader, and schema for a csv file:

```
SELECT *
FROM TABLE(dfs.tmp.`cars.csvh-test`(
  type => 'text',
  fieldDelimiter => ',',
  extractHeader => true,
  schema => 'inline=(col1 date)'))
```

Use `allTextMode` for a json file:

```
SELECT *
FROM TABLE(dfs.tmp.`students`(type => 'json', allTextMode => true))
```

Dynamic parameters

This is a list of parameters for common formats.

CAUTION: The default value will be used if the parameter wasn't set either in the storage plugin or the format plugin table function.

Table

Parameter name	Default value	Description
<code>lineDelimiter</code>	<code>\n</code>	A string used as a line delimiter in the text file.
<code>fieldDelimiter</code>	<code>,</code>	A character used as a field delimiter in the text file.
<code>quote</code>	<code>"</code>	Defines the character used to enclose text fields that may contain delimiters, line breaks, or other special characters. For example, when quote is <code>"</code> , a field value such as <code>"New York, NY"</code> is treated as a single column value even though it contains a comma.
<code>escape</code>	<code>"</code>	Specifies the character used to escape a quotation mark inside a quoted field. For example, with escape set to <code>"</code> , the value <code>"He said ""Hello"""</code> will be parsed as <code>He said "Hello"</code> .
<code>comment</code>	<code>#</code>	Identifies the character that marks the beginning of a comment line. Any line starting with this character is ignored during parsing. For example, if comment is <code>#</code> , then a line beginning with <code>#</code> is treated as a comment.
<code>skipFirstLine</code>	<code>false</code>	A Boolean value that indicates whether the first line in the text file should be omitted.
<code>extractHeader</code>	<code>false</code>	A Boolean value that indicates whether the first valid record parsed from the text file should be considered as the row containing the names of each column.

Table

Parameter name	Default value	Description
<code>allTextMode</code>	The value defined in <code>store.json.all_text_mode</code> . Default value is <code>false</code> .	A Boolean option that forces all fields in JSON files to be read as <code>VARCHAR</code> . This helps prevent schema change errors when field types vary between records.
<code>readNumbersAsDouble</code>	The value defined in <code>store.json.read_numbers_as_double</code> . Default value is <code>false</code> .	A Boolean value. If <code>true</code> , all numeric values are read as <code>DOUBLE</code> , regardless of whether they include a decimal point.
<code>skipMalformedJSONRecords</code>	The value defined in <code>store.json.reader.skip_invalid_records</code> . Default value is <code>false</code> .	A Boolean value that enables the JSON reader to skip malformed or invalid records in JSON files. When set to <code>true</code> , Drill ignores these records and continues processing the remaining data, rather than terminating the query.

Table (Continued)

Parameter name	Default value	Description
escapeAnyChar	The value defined in <code>store.json.reader.allow_escape_any_char</code> . Default value is <code>false</code> .	A Boolean value that enables the JSON record reader to escape any character when processing JSON data.
nanInf	The value defined in <code>store.json.reader.allow_nan_inf</code> . Default value is <code>true</code> .	A Boolean value that enables the JSON record reader to interpret NaN and Infinity tokens in JSON data as numeric values.

Table

Parameter name	Default value	Description
allTextMode	<code>false</code>	A Boolean option that forces all fields in the MapR-DB table to be read as VARCHAR. This helps prevent schema change errors when field types vary between records.
enablePushdown	<code>true</code>	Enables query pushdown to the MapR-DB engine. When set to <code>true</code> , Drill delegates supported filters and projections directly to MapR-DB for improved performance.
ignoreSchemaChange	<code>false</code>	Allows queries to continue even when schema changes are detected in MapR-DB tables. When enabled, Drill ignores schema inconsistencies instead of failing the query.
readAllNumbersAsDouble	<code>false</code>	A Boolean value. If set to <code>true</code> , all numeric values are read as DOUBLE, regardless of whether they include a decimal point.
disableCountOptimization	<code>false</code>	Disables the optimization that uses table metadata to compute <code>COUNT(*)</code> queries more efficiently. When set to <code>true</code> , Drill performs a full scan instead of using the optimization.
readTimestampWithZoneOffset	<code>false</code>	When set to <code>true</code> , Drill converts timestamp values from UTC to the local time zone.
nonExistentFieldSupport	<code>true</code>	Enables support for queries that reference fields not present in all documents. When set to <code>true</code> , Drill treats missing fields in MapR-DB records as NULL.
index	-	A string value that specifies a hint for the secondary index table to use when executing queries on MapR-DB. If not set, Drill automatically evaluates available indexes, computes their costs, and selects the most efficient one.

Schema provisioning using a table function

Schema provisioning defines explicit schemas so that Apache Drill reliably interprets text/JSON/MapR-DB JSON data.

You can define a schema for text files and JSON MapR-DB tables. The schema can be provided in two ways:

1. Placed in the root directory of the text table. For more information, see <https://drill.apache.org/docs/create-or-replace-schema/>.
2. Supplied to individual queries using a [table function](#).

This topic describes the second approach, in which the schema is provided through a table function.

Use cases

In Apache Drill, users can query different storage and data formats. Some formats have a schema (parquet), some formats have an inferred schema (json), and for some formats, data is read as varchar only (csv). For the latter case, the user has to use casts to indicate which format is actually stored in the file, although there are some cases where casts cannot help and the query will fail. Even if casts do help, at some point the user might want to avoid repeating the same casts in every query (casting an HBase column to a Double, casting a CSV column to a double, etc). Providing the schema up front helps to resolve these issues.

Following are the major error cases of incorrect schema inference and schema change exception.

Incorrect schema inference

This example assumes that there is a json with two records:

```
{a: 10} {a: 10.1}
```

Apache Drill assumes that the column type is **BigInt** and fails with the following exception:

Error: INTERNAL_ERROR ERROR: You tried to write a Float8 type when you are using a ValueWriter of type NullableBigIntWriterImpl.

Because casts are not pushed down into the scan, adding casts also does not help and the same error is returned:

```
SELECT cast(a AS DOUBLE) FROM file.json
```

The same schema change issues will occur if the column has a mix of data types that do not belong to the same group, for example, integer, decimal, varchar. There is currently an option to help the user query such data by treating all data as varchar, but it is only applicable for json format.

Schema evolution

This example assumes that there are two json files, both of which have the same column but different numeric types.

```
myDir /
      | - File 1: {a: 10}
      | - File 2: {a: 10.1}
```

If a user queries either file individually, the query succeeds; however, when querying the files together, a SchemaChangeException may occur on blocking operators.

```
SELECT a, count() FROM myDir GROUP BY a
```

*UNSUPPORTED_OPERATION ERROR: Schema changes not supported in External Sort.
Please enable Union type.*

*Previous schema BatchSchema [fields=[[`a` (BIGINT:OPTIONAL)], [`\$f1` (INT:REQUIRED)]],
selectionVector=NONE]*

*Incoming schema BatchSchema [fields=[[`a` (FLOAT8:OPTIONAL)], [`\$f1` (INT:REQUIRED)]],
selectionVector=NONE]*

This can be resolved by adding casts in the query:

```
SELECT cast(a AS DOUBLE), count() FROM myDir GROUP BY 1
```

Syntax

The schema can be provided using the Drill table function with the schema parameter. You can define the schema in a file and specify the path to that file in the table function.

For details on how to create a schema file, see <https://drill.apache.org/docs/create-or-replace-schema/>.
Syntax:

```
table(<table_name>(schema => 'path=`<path to the schema>`'))
```

For example:

```
select * from table(dfs.tmp.`text_table`(schema => 'path=`/tmp/my_schema`'))
```

Or the schema can be defined inline, directly within the query:

```
<table_name>(schema => 'inline=(<column-name> <type> [NOT NULL]
[default <value>] [properties {<col-prop>=<value>, ...}], ...) properties
{<schema-prop>=<value>, ...}'))
```

For example:

```
inline=(
  `user name` VARCHAR NOT NULL default `unknown`,
  `credit card number` VARCHAR properties {`drill.blank-as`=`null`,
  `drill.special`=`true`}
) properties {`drill.special`=`true`}
```

The general syntax for an inline schema is as follows:

```
inline=(<Column Definition>, ...) <Schema properties>
```

The inline schema is recognized based on the following ANLR grammar: <https://github.com/apache/drill/blob/master/exec/vector/src/main/antlr4/org/apache/drill/exec/record/metadata/schema/parser/SchemaParser.g4>

Column Definition

The column definition follows this structure:

```
<column-name> <type> [NOT NULL] [default <value>] [properties
{<key>=<value>, ...}]
```

Column Name required

The name of the column. It must be enclosed in backticks if it contains spaces or special characters. For example:

```
`user name`
email
```

Column Type required

Specifies the data type of the column (case-insensitive). Data types can be primitive and complex. Apache Drill [supports most of the primitive data types](#). Parentheses should be used to provide type length, precision, and scale. Indicating the length for a varchar is optional.

Table

SQL Data Type	Description	Example
UINT1	Unsigned 1-byte integer	255
UINT2	Unsigned 2-byte integer	65535
UINT4	Unsigned 4-byte integer	4294967295
UINT8	Unsigned 8-byte integer	18446744073709551615
TINYINT	1-byte signed integer	127
SMALLINT	2-byte signed integer	32767
INT INTEGER	4-byte signed integer in the range -2,147,483,648 to 2,147,483,647	2147483646
BIGINT	8-byte signed integer in the range -9,223,372,036,854,775,808 to 9,223,372,036,854,775,807	9223372036854775807
BINARY(p) VARBINARY(p)	Variable-length byte string p – precision	B@e6d9eb7
BOOLEAN	True or false	true
DATE	Years, months, and days in YYYY-MM-DD format since 4713 BC	2015-12-30
DEC(p,s) DECIMAL(p,s) NUMERIC(p,s)	38-digit precision number. p – precision s – scale	DECIMAL(6,2) is 1234.56, 4 digits before and 2 digits after the decimal point
FLOAT	4-byte floating point number	0.456
DOUBLE	8-byte floating point number, precision-scalable	0.456
INTERVAL	A day-time or year-month interval	'1 10:20:30.123' (day-time) or '1-2' year to month (year-month)
SMALLINT	2-byte signed integer in the range -32,768 to 32,767	32000
TIME	24-hour based time before or after January 1, 2001 in hours, minutes, seconds format: HH:mm:ss	22:55:55.23
TIMESTAMP	JDBC timestamp in year, month, date hour, minute, second, and optional milliseconds format: yyyy-MM-dd HH:mm:ss.SSS	2015-12-30 22:55:55.23
CHAR(length) CHARACTER(length) CHARACTER VARYING(length) VARCHAR(length)	UTF8-encoded variable-length string. The default limit is 1 character. The maximum character limit is 2,147,483,647.	CHAR(30) casts data to a 30-character string maximum.

Table (Continued)

SQL Data Type	Description	Example
LATE DYNAMIC	An internal data type that may appear in schemas but is not intended for direct use by end users.	-

When specifying complex types in a schema, the diamond (<>) syntax must be used.

Table

SQL Data Type	Description	Example
ARRAY	An array is a repeated list of values. Each element can be a scalar type, such as a VARCHAR or INTEGER, or a complex type, such as a MAP or another ARRAY.	ARRAY<INT> ARRAY<VARCHAR> ARRAY<ARRAY<INT>> ARRAY<STRUCT<s1 INT not null, s2 INT>>
STRUCT	A set of named values, each with its own data type. It is similar to an object, where each field can contain a scalar or complex value. Each field within a STRUCT can hold a simple or a complex type.	STRUCT<s1 INT, s2 INT> STRUCT<s1 INT not null, s2 VARCHAR(10)> stSTRUCT<s1 INT, ARRAY<INT>> STRUCT<s1 INT not null, s2 STRUCT<ss1 INT, ss2 INT>>
UNION	An internal data type that may appear in schemas but is not intended for direct use by end users.	-
MAP	An internal data type that may appear in schemas but is not intended for direct use by end users.	-

Nullability optional

The keyword NOT NULL indicates that the column cannot contain null values. If this keyword is not specified, the column is considered nullable by default.

Column properties optional

There are two built-in column properties: FORMAT and DEFAULT, which are defined using the corresponding case-insensitive keywords. The value for each property must be enclosed in single quotes. Both keywords are optional; however, when used together, their declaration order is strict. The FORMAT keyword must appear before DEFAULT, and both must be specified after the column definition. Examples:

```
col DATE NOT NULL FORMAT `yyyy-MM-dd`
col DATE NOT NULL DEFAULT `2019-01-01`
col DATE NOT NULL FORMAT `yyyy-MM-dd` DEFAULT `2019-01-01`
```

Other properties can be indicated after PROPERTIES clause:

```
col DATE NOT NULL FORMAT `yyyy-MM-dd` DEFAULT `2019-01-01` PROPERTIES
{`drill.blank-as` = `null`}
```

There is no limitation in the parser regarding which column types `FORMAT`, `DEFAULT`, and `PROPERTIES` can be defined. If the reader implementation is able to use any of them, they will be utilized; otherwise, they will be ignored.

Table

Property name	Description	Example
FORMAT drill.format	Specifies the date/time format pattern (Joda Time syntax) used to convert string values to date/time types. Recommended for accurate parsing of date/time columns. If not set, Drill uses ISO date/time formats by default (e.g., yyyy-MM-dd 'T' HH:mm:ssZZ for timestamps). Format can be indicated using two ways: via <code>FORMAT</code> keyword (before <code>DEFAULT</code> keyword) or in the column properties section.	start_date format `yyyy-MM-dd` start_date date properties {`drill.format` = `yyyy-MM-dd`}
DEFAULT drill.default	Specifies a custom default value for non-nullable (required) columns that are missing in the data. Drill uses this value instead of the natural default (e.g., 0 for numbers). Has no effect for nullable columns. Can be set using the <code>DEFAULT</code> keyword or in the column's properties.	id int not null default '-1' id int not null properties {`drill.default` = '-1'}
drill.special	Indicates whether to project the column in a wildcard (*) query. Special columns may be excluded from projection. Certain "special" columns may be available only when explicitly requested. Default false	col VARCHAR PROPERTIES {`drill.special` = `true`}
drill.blank-as	Indicates how to handle blanks. The value should be either <code>null</code> or <code>0</code> . <code>0</code> – convert blanks for numeric fields to 0. For non-numeric fields, convert to null (for nullable) or the default value (for non-nullable). <code>null</code> – convert blanks to null values (if the column is nullable), or fill with the default value (non-nullable). This is not intended for direct use by end users.	-

Schema properties optional

Schema properties are defined in an inline schema using the `PROPERTIES` clause, which appears after the column definition list enclosed in parentheses. The syntax is identical to the Column properties syntax. For example:

```
(col VARCHAR PROPERTIES {`drill.blank-as` = `null`}) PROPERTIES
{`drill.strict` = `true`}
```

Table

Property name	Description	Example
drill.strict	<p>If true, Drill enforces a strict schema: any columns in the data but not defined in the schema are ignored, and queries for such columns return NULL.</p> <p>If false, Drill includes extra columns found in the data after the schema-defined columns.</p> <p>Default false</p>	(col VARCHAR PROPERTIES {drill.blank-as = null}) PROPERTIES {drill.strict = true}

Schema provisioning for MapR-DB JSON tables

Starting with DEP10.0.0, Drill supports schema provisioning for MapR-DB JSON tables. Unlike text and standard JSON formats, the Drill MapR-DB JSON reader uses the provided schema **only** when a column's type is ambiguous – for example, if all values in the first batch are missing or null. All other columns and schema properties are ignored.

Drill Limitations

Provides information about Drill limitations and solutions where applicable.

Max Drill Query Size Depends on ZooKeeper jute.maxbuffer Value

Issue

Drill cannot run a query that exceeds the ZooKeeper `jute.maxbuffer` value of 1 MB.

Solution

For the ZooKeeper `jute.maxbuffer` property, follow the recommendations in the ZooKeeper documentation.

CAUTION: The `jute.maxbuffer` property is marked as an unsafe option. Do not change it to a higher value to run larger queries. For additional details about why this property is unsafe, see the Apache Zookeeper documentation: <https://zookeeper.apache.org/doc/r3.6.2/zookeeperAdmin.html>

The following error indicates that the query is too large. To resolve this error, rewrite the query to fit within the `jute.maxbuffer` limit:

```
Query execution error. Details:
EXECUTION_ERROR ERROR: Failed to
persist query info. Query length is
too big.
```

In Drill EEP version 8.1.0 and earlier and EEP version 9.1.1 and earlier, the following type of error may also indicate that the query is too large:

```
Query execution
error. Details: SYSTEM
ERROR: ConnectionLossException:
KeeperErrorCode =
ConnectionLoss for /drill/running/
1bb44a40-c715-7b38-c310-05de39dfb3e7
```

In Drill EEP version 8.1.1, this error could indicate that the `jute.maxbuffer` value set for the Drillbit does not correspond with the ZooKeeper `jute.maxbuffer` value.

To change the value of `jute.maxbuffer` in Drill, add the `-Djute.maxbuffer` Java property to `DRILL_JAVA_OPTS` in `<drill_home>/conf/drill-env.sh`, as shown in the following example:

```
export
DRILL_JAVA_OPTS="$DRILL_JAVA_OPTS -Djute.maxbuffer=9000000
```

If you change the `jute.maxbuffer` value, you must update the system property on all servers (ZooKeeper nodes) and clients (Drillbit nodes) to have the same value. Failure to change the value on all servers and clients can result in further errors.

Working with subqueries

- The SELECT list in a scalar subquery can only contain one item/column.
- Correlated subqueries should return exactly one row.
- The WHERE clause of a subquery should not refer to more than one column of the table in the outer query.

Queries on JSON Files and Tables in HPE Data Fabric Return an OutOfMemoryException

An architectural limitation in Apache Drill can cause an overconsumption of memory when Drill queries files or tables with a certain JSON structure, resulting in an `OutOfMemoryException`.

Drill may return an `OutOfMemoryException` for queries that run against JSON files stored in HPE Data Fabric Database and HPE Data Fabric File Store that have many key-value pairs if the queries include the key-value pairs.

For example, the following JSON files could cause Drill to return an `OutOfMemoryException` when queries that include the key-value pairs run against the files:

JSON file with objects that have many key-value pairs

```
{
  "context" : {
    "1": "a",
    "2": "b",
    "3": "c",
    ... // many key-value pairs;
    not showing 9996 of them
    "10000": "d"
  }
}
{
  "context" : {
    "10001": "b"
    ... //many key-value pairs;
    not showing 19998 of them
    "30000": "z"
  }
}
{
```

```

    "context" : {
      "3": "c"
    }
  }
  {
    "context" : {
      "3": "c"
    }
  }
  {
    "context" : {
      "5": "e"
    }
  }
}

```

JSON file with thousands of objects, each having a unique key

```

{
  "context" : {
    "1": "a"
  }
}
{
  "context" : {
    "2": "b"
  }
}
{
  "context" : {
    "3": "c"
  }
}
{
  "context" : {
    "4": "d"
  }
}
{
  "context" : {
    "5": "e"
  }
}
}

```

In this scenario, if a JSON file contains thousands of objects with unique keys (in 30,000+ documents), the following query would cause an `OutOfMemoryException`:

```

SELECT context FROM
maprfs.`folderWithJSONDocuments`;

```

Issue Cause

Drill was designed to run queries against massive amounts of data. To successfully run such queries, Drill has a columnar execution engine that works with vectors. Drill creates a separate vector for each unique key and then allocates memory to each vector. Each vector stores about 1,024 values, which varies slightly depending on the data type of the value.

In the following illustration, each key has a VARCHAR value and Drill creates a `NullableVarCharVector` for each unique key:

JSON

```

{
  "context" : {
    "50122" : "5012",
    "50911" : "5115",
    "46122" : "4612",
    ...
    "11078" : "1390"
  }
}

```

Drill allocates 40960 bytes of direct memory to each `NullableVarCharVector`. You can see how Drill fills each vector with 7 bytes (2 bytes for a single CHAR string, like "a" and 5 bytes for internally used values).

In cases where Drill is querying thousands upon thousands of JSON files, this works well. However, in cases where Drill queries a single file, a memory issue occurs because each key-value pair in the JSON file may consume more than 1000x more memory than is required for the corresponding value. Each vector unnecessarily holds memory for several values, resulting in failed queries due to a memory shortage.

Refer to [Value Vectors](#) for more information about vectors in Drill.

Issue Resolution

To resolve or prevent this issue, change the format of the key-value pairs in the JSON file from an object to an array of objects, as shown in the following example:

```

{
  "context" : [
    {
      "key": "1",
      "value": "a"
    },
    {

```

```

    "key": "2",
    "value": "b"
  },
  {
    "key": "3",
    "value": "c"
  },
  ...,
  {
    "key": "100000",
    "value": "z"
  }
]
}

```

When a JSON file has an array of objects, Drill only creates two NullableVarCharVectors – one for the "key" and one for the "value". With this structure, only two vectors need to hold memory.

In the following illustration, you can see how Drill fills two vectors with many values versus filling thousands of vectors with only a few values:

Unequal JOIN Support

By default, unequal joins are disabled in Drill because Drill does not have optimized JOIN operators to process these types of queries. An unequal join contains a condition with an inequality comparison between columns. An unequal join uses operators, such as $<>$, $<$, $>$, $<=$, or $>=$ to establish the relationship between the joined columns. For example:

```

SELECT *
FROM table1
JOIN table2
ON table1.column_name <= table2.column_name;

```

By default, if you run a query with an unequal join, the query fails and Drill returns the following error:

```
Error: UNSUPPORTED_OPERATION ERROR: This query cannot be planned possibly
due to either a cartesian join or an inequality join.
If a cartesian or inequality join is used intentionally, set the option
'planner.enable_nljoin_for_scalar_only' to false and try again.
```

Although Drill does not have optimized JOIN operators, Drill can process these types of queries in a non-efficient way using a nested loop join operator. To enable this, set the `planner.enable_nljoin_for_scalar_only` option to false. Drill can then execute LEFT and INNER joins; however, RIGHT joins will still fail with the error message shown.

Even when `planner.enable_nljoin_for_scalar_only` is disabled, Drill may still return an `UNSUPPORTED_OPERATION ERROR` for LEFT joins due to the join optimizations in Drill. If Drill detects that the right input is larger than the left, Drill optimizes the join such that the left and right inputs are flipped and the LEFT join type will be changed to RIGHT. If the query contains non-equi joins, after such optimizations, the query will fail because the nested loop join operator does not allow RIGHT joins.

Using the following query as an example:

```
SELECT *
FROM table1
LEFT JOIN table2
ON table1.column_name <= table2.column_name;
```

If `table1` is smaller than `table2` or even empty, Drill applies a join optimization on the query and the query fails with the following error:

```
Error: UNSUPPORTED_OPERATION ERROR: This query cannot be planned possibly
due to either a cartesian join or an inequality join.
If a cartesian or inequality join is used intentionally, set the option
'planner.enable_nljoin_for_scalar_only' to false and try again.
```

The same optimization can make a RIGHT join executable when the left input is smaller than the right. In this case, the left and right inputs will be flipped and the RIGHT join type will be changed to LEFT. The nested loop operator supports LEFT joins. This is how Drill executes a query with a RIGHT join and no errors.

To avoid non-equi join errors, disable the join optimization by setting the `planner.enable_join_optimization` option to false.

IMPORTANT: Join optimizations improve query performance. If you disable the `planner.enable_join_optimization` option, it disables optimizations for all join types. If you need to disable this option for non-equi joins, only disable the `planner.enable_join_optimization` option at the session level using the ALTER SESSION SET command or through the Drill Web UI.

Vulnerability Reports

Provides vulnerability information in relation to Drill.

CVE-2022-42889

This vulnerability *does not* impact Drill. The `commons-text` in Drill is only used for the following `StringDistanceFunctions` that involve classes from a [similarity](#) package:

- `cosine_distance`
- `fuzzy_score`

- `hamming_distance`
- `jaccard_distance`
- `jaro_distance`
- `levenshtein_distance`
- `longest_common_substring_distance`

Drill *does not* use `StringSubstitutor`, which is what produces the vulnerability.

Apache Flink

Apache Flink is a framework and distributed processing engine for stateful computations over unbounded and bounded data streams.

This Section contains the information about the implementation of Apache Flink from Data Fabric Ecosystem Pack.

Installing Flink

You can download and install, Flink from the DEP repository.

See [Installing Flink](#) on page 294 for more information.

Configuring Flink

Describes how to configure Flink.

Flink Overview

The default configuration directory is in:

```
/opt/mapr/flink/flink-<version>/conf
```

This path can be changed with `FLINK_CONF_DIR` environment variable.

See the following Apache Flink documentation on configuring Flink:

- [Configuration](#) for details on configuration directory in general, and the main configuration file is `config.yaml`.
- [How to use logging](#) for details on different logging files.

Default Configuration

Data Fabric Ecosystem Pack applies the default configuration on top of Apache Flink default configuration, for example:

- TLS/SSL is enabled by default. See [Security in Flink](#) on page 4903 for details.

Using MapR-FS as a checkpoint storage

Flink on Data Fabric supports storing checkpoint data in MapR-FS. You can specify a `maprfs://` URL in `execution.checkpointing.dir` as follows:

```
execution:
  checkpointing:
    dir: maprfs:///user/<username>/flink/checkpoints
```

Integrating Flink with ZooKeeper for High Availability

Flink on Data Fabric supports integration with ZooKeeper for high availability. You can specify a Data Fabric's ZooKeeper quorum in `high-availability.zookeeper.quorum` as well as a `maprfs://` URL in `high-availability.storageDir` as follows:

```
high-availability:
  storageDir: maprfs:///user/mapruser1/flink/ha
  zookeeper:
    quorum: <host name>:5181
```

Configuring Flink for use with Kerberos

To run Flink with Kerberos on DEP, you must add `-Dhadoop.login=hybrid` to the `env.java.opts.all` setting in `config.yaml`, configure the `security.kerberos.login` section with the correct keytab, principal, and JAAS contexts, restart or start a Flink YARN session in detached mode, confirm in the logs that Kerberos authentication has succeeded, and then verify that your jobs are producing data correctly by consuming from Kerberos-protected Kafka topics with Kerberos-enabled clients.

1. Modify the Flink `config.yaml` file to add `-Dhadoop.login=hybrid` to `env.java.opts.all`:

```
env:
  java:
    opts:
      all: --add-exports=java.base/sun.net.util=ALL-UNNAMED
          --add-exports=java.rmi/sun.rmi.registry=ALL-UNNAMED
          --add-exports=jdk.compiler/
com.sun.tools.javac.api=ALL-UNNAMED
          --add-exports=jdk.compiler/
com.sun.tools.javac.file=ALL-UNNAMED
          --add-exports=jdk.compiler/
com.sun.tools.javac.parser=ALL-UNNAMED
          --add-exports=jdk.compiler/
com.sun.tools.javac.tree=ALL-UNNAMED
          --add-exports=jdk.compiler/
com.sun.tools.javac.util=ALL-UNNAMED
          --add-exports=java.security.jgss/
sun.security.krb5=ALL-UNNAMED
          --add-opens=java.base/java.lang=ALL-UNNAMED
          --add-opens=java.base/java.net=ALL-UNNAMED
          --add-opens=java.base/java.io=ALL-UNNAMED
          --add-opens=java.base/java.nio=ALL-UNNAMED
          --add-opens=java.base/sun.nio.ch=ALL-UNNAMED
          --add-opens=java.base/java.lang.reflect=ALL-UNNAMED
          --add-opens=java.base/java.text=ALL-UNNAMED
          --add-opens=java.base/java.time=ALL-UNNAMED
          --add-opens=java.base/java.util=ALL-UNNAMED
          --add-opens=java.base/java.util.concurrent=ALL-UNNAMED
          --add-opens=java.base/java.util.concurrent.atomic=ALL-UNNAMED
          --add-opens=java.base/java.util.concurrent.locks=ALL-UNNAMED
          -Dhadoop.login=hybrid
```

2. In the same `config.yaml` file, uncomment and modify the Kerberos properties as appropriate for your environment:

```
security:
  kerberos:
    login:
      use-ticket-cache: true
```

```
# keytab: /home/mapruser1/mapruser1.keytab
principal: mapruser1/node1.cluster.com@NODE1
# The configuration below defines which JAAS login contexts
contexts: Client,KafkaClient
```

- `use-ticket-cache`:
 - `true` to use the existing Kerberos ticket cache (if available).
- `keytab`: Path to the keytab file for the service/user that will run Flink.
- `principal`: Kerberos principal associated with the keytab.
- `contexts`: JAAS login contexts that should use this configuration. In this example, both generic `Client` and `KafkaClient` contexts are enabled.

Starting and Stopping a Flink Cluster

Describes how to start and stop a Flink cluster.

Deployment Modes

Only YARN is supported as a resource manager for Flink, in DEP 10.0.0. Flink on YARN supports both session and application modes of deployment. For more information, see the following Apache Flink documentation pages:

- [Deployment Modes](#)
- [Deployment Modes Supported by Flink on YARN](#).

IMPORTANT: The DEP-Flink CLI and Apache-Flink CLI are similar, and the commands are same for both CLIs. The only difference is that all commands start with the `/opt/mapr/flink/flink-<version>/bin/` prefix in DEP-Flink CLI.

IMPORTANT: You can see the Flink documentation page: [Command-Line Interface](#) for the latest information. The following commands for starting/stopping a Flink cluster are shown as an example.

Starting a Flink Cluster

Session mode

Use the `yarn-session.sh` script, and start the Flink cluster with the following command:

```
/opt/mapr/flink/flink-<version>/bin/yarn-session.sh --detached
```

Application mode

In application mode, use the following command for both starting a cluster, and submitting a job:

```
/opt/mapr/flink/flink-<version>/bin/flink run -t yarn-application <job_jar>
```

**NOTE:**

- With Application mode, you can configure `yarn.classpath.include-user-jar` to `DISABLED` to avoid the error similar to:

```
org.apache.flink.api.common.functions.InvalidTypesException: The
types of the interface
    <class> could not be inferred. Support for synthetic
interfaces, lambdas, and generic or raw
    types is limited at this point
```

for example, you can add the following to `config.yaml` file to avoid the preceding error:

```
yarn:
  classpath:
    include-user-jar: DISABLED
```

- Also, if you use any Schema Registry client libraries, ensure that you exclude all `org.apache.zookeeper:*` dependencies. for example:

```
<dependency>
  <groupId>io.confluent</groupId>
  <artifactId>kafka-avro-serializer</artifactId>
  <version>${schema.registry.version}</version>
  <exclusions>
    <exclusion>
      <groupId>org.apache.zookeeper</groupId>
      <artifactId>zookeeper</artifactId>
    </exclusion>
  </exclusions>
</dependency>
```

Stopping a Flink cluster Session Mode

To gracefully stop a cluster, you must have the YARN application ID of the cluster. See the YARN application list or search in Flink logs to find the ID.

Once you have the YARN application ID, use the following command to stop the cluster:

```
echo "stop" | /opt/mapr/flink/flink-<version>/bin/yarn-session.sh -id
<application_id>
```

**NOTE:**

- The user who started the Flink cluster can only stop the cluster gracefully.
- Cluster administrator can end the YARN application directly. However, if you end the application, some uncleaned resources may remain.

Application Mode

1. To stop a Flink cluster in application mode, you need to end all jobs running on the cluster. To end a particular job, you must have both YARN application id and the Job ID. The Job ID is printed in console upon submitting a job. Alternatively, you can also find the Job ID by listing all the running jobs on the cluster as follows:

```
/opt/mapr/flink/flink-<version>/bin/flink list -t
yarn-application -Dyarn.application.id=<application_id>
```

2. Using Flink CLI, you can cancel (ending without saving point) a job, as shown in the following example:

```
/opt/mapr/flink/flink-<version>/bin/flink cancel -t
yarn-application -Dyarn.application.id=<application_id> <job_id>
```

Configuring mapR ticket expiration time

Any long-running YARN job may fail due to ticket expiration. Before submitting a YARN job that runs for a longer period, consider configuring the expiration time.

You can configure the timing in either of the following ways:

- Globally (for all YARN jobs in a cluster), specify the `yarn.mapr.ticket.expiration` value in `yarn-site.xml` (default value, one week). Or
- Alternatively, you can increase the expiration time of a specific YARN job (default value, two weeks), as follows:

1. Generate a ticket and specify the duration:

```
maprlogin password -duration <duration>
```

2. Submit a YARN job (start the Flink cluster).
3. (Optional) Remove the generated ticket: `maprlogin logout`

NOTE: YARN chooses the maximum expiration time between the two values from the generated tickets.

Building a Flink Job with Maven

Describes how to build a Flink job with Maven.

Overview

Currently, only DataStream API is supported for Flink on Data Fabric Ecosystem Pack.

The application development process in DEP Flink differs from Apache Flink only in using DEP specific Maven dependencies instead of Apache specific maven dependencies.

For more information on how to write Flink jobs, see the following Apache Flink documentation:

- [Project Configuration](#)
- [DataStream API](#)

The following sections describe the differences in the Project Configuration between Flink on Data Fabric and Apache Flink.

DF Streams integration

To enable DF Streams integration in `flink-connector-kafka`, use the applicable version of the dependency in your project. Following is an example for DEP10.0.0 version:

```
<dependency>
  <groupId>org.apache.flink</groupId>
  <artifactId>flink-connector-kafka</artifactId>
  <version><4.0.0.0-dep-1000></version>
</dependency>
```

DEP Schema Registry integration

If you use Schema Registry client-libraries (for example, Avro serializer), you must switch to a DEP specific version. The following is an example for DEP10.0.0 version:

```
<dependency>
  <groupId>io.confluent</groupId>
  <artifactId>kafka-avro-serializer</artifactId>
  <version>7.6.0.400-dep-1000</version>
  <exclusions>
    <!-- We want to take ZooKeeper from cluster, otherwise it
might cause NoSuchMethodError -->
    <exclusion>
      <groupId>org.apache.zookeeper</groupId>
      <artifactId>zookeeper</artifactId>
    </exclusion>
  </exclusions>
</dependency>
```

Submitting a Flink Job

Describes about how to submit a Flink job.

IMPORTANT: The DEP-CLI and Flink-CLI works same, and the commands are same too. The only difference is that all commands in DEP-CLI start with the `/opt/mapr/flink/flink-<version>/bin/` prefix.

IMPORTANT: You can see the Flink documentation page: [Command-Line Interface](#) for the latest information. Following commands for starting/stopping a Flink cluster are shown as an example.

Session mode

To submit a job in session mode, run the following command:

```
/opt/mapr/flink/flink-<version>/bin/flink run -d <job_jar>
```

Application mode

In application mode, use the following command for both starting a cluster, and submitting a job:

```
/opt/mapr/flink/flink-<version>/bin/flink run -t yarn-application
  <job_jar>
```

**NOTE:**

- With Application mode, you might want to configure [yarn.classpath.include-user-jar](#) to DISABLED to avoid the error similar to:

```
org.apache.flink.api.common.functions.InvalidTypesException: The
types of the interface
    <class> could not be inferred. Support for synthetic
interfaces, lambdas, and generic or raw
    types is limited at this point
```

for example, you can add the following to config.yaml file to avoid the preceding error:

```
yarn:
  classpath:
    include-user-jar: DISABLED
```

- Also, if you use any Schema Registry client libraries, ensure that you exclude all `org.apache.zookeeper:*` dependencies. for example:

```
<dependency>
  <groupId>io.confluent</groupId>
  <artifactId>kafka-avro-serializer</artifactId>
  <version>${schema.registry.version}</version>
  <exclusions>
    <exclusion>
      <groupId>org.apache.zookeeper</groupId>
      <artifactId>zookeeper</artifactId>
    </exclusion>
  </exclusions>
</dependency>
```

Security in Flink

Describes about the Security in Flink.

TLS/SSL

DEP Flink generates self-signed certificates and enables TLS/SSL automatically, .

The TLS introduces some known warnings. See [Flink 2.0.0.0 - 2510 \(DEP 10.0.0\) Release Notes](#) on page 7881 for more information.

For more information on how to apply your custom TLS/SSL configuration, see [SSL Setup](#) page of Apache Flink documentation.

Authentication

IMPORTANT: Apache Flink also recommends having external authentication proxy, see [External / REST Connectivity](#) page for more information.

Once the TLS handshake happens between a client and a Job Manager, no further client authentication happens in Flink. However, to secure the Flink cluster, do the following:

1. Isolate the Flink deployment on network layer (for example, with firewall).
2. Enable mutual TLS authentication and only allow trusted clients to connect.

Impersonation or Multi-tenancy

Impersonation or Multi-tenancy is not supported. The user is expected to run the Flink cluster job with the respective mapr ticket file.

NOTE: It is recommended to make a copy of the conf directory from the Flink distribution and modify the settings on a per-user basis. You can specify a different configuration directory location by defining the FLINK_CONF_DIR environment variable. See [Configuration](#) page for more information.

Flink SQL Client and Iceberg Integration Demo

This reference provides key commands and configurations for sourcing and sinking data between Data Fabric Streams and Iceberg tables managed by DEP Polaris, by using the Flink SQL client.

Overview

This reference covers a basic integration scenario for Data Fabric Streams and Iceberg tables by using DEP Polaris. For additional information, see:

- [Apache Flink: Table API & SQL](#)
- [Apache Iceberg: Flink integration](#)
- [Apache Polaris](#) on page 5375

Preparation

The following sections describe the preparation for the demo for sourcing and sinking data between Data Fabric Streams and Iceberg tables.

Data Fabric Streams topic creation

Create the stream and the necessary topics:

```
maprcli stream create -path /user/mapruser1/s
maprcli stream topic create -path /user/mapruser1/s -topic input_employees
maprcli stream topic create -path /user/mapruser1/s -topic
output_employees
```

Produce a sample record to the input topic:

```
echo '0,Alice,0'
| /opt/mapr/kafka/kafka-3.6.1/bin/kafka-console-producer.sh --topic /user/
mapruser1/s:input_employees
```

Flink configuration

Pass the AWS_REGION environment variable to both Job Manager and Task Managers:

```
containerized:
  master:
    env:
      AWS_REGION: "us-east-1"
  taskmanager:
    env:
      AWS_REGION: "us-east-1"
```

Enable checkpoints for Iceberg writes. For the demo purposes, you can set a short checkpoint interval to see results faster:

```
execution.checkpointing.interval: 10s
execution.checkpointing.dir: maprfs:///path/to/checkpoints/dir
```

Downloading libraries

Create a directory for extra libraries:

```
mkdir ~/user-libs
```

You would require the following JAR files for the demo:

- **flink-csv:** To work with CSV records
- **flink-sql-connector-kafka:** To source and sink data from and to Data Fabric Streams
- **iceberg-flink-runtime:** Already included in the mapr-flink package

Download the missing jars to the directory:

```
wget -P ~/user-libs \
https://repository.mapr.com/maven/org/apache/flink/
flink-sql-connector-kafka/4.0.0.0-dep-1000/
flink-sql-connector-kafka-4.0.0.0-dep-1000.jar \
https://repository.mapr.com/maven/org/apache/flink/flink-csv/
2.0.0.0-dep-1010/flink-csv-2.0.0.0-dep-1010.jar
```

The following sections in the given sequence demonstrate the sourcing and sinking of data between Data Fabric Streams and Iceberg tables, by using Flink SQL client and Polaris catalog.

Starting a Flink cluster

This demo assumes a running Flink cluster. If you don't have a Flink cluster, start a YARN session cluster:

```
/opt/mapr/flink/flink-2.0.0/bin/yarn-session.sh --detached
```

Starting the SQL client

Start the Flink SQL client and provide it with the downloaded libraries:

```
/opt/mapr/flink/flink-2.0.0/bin/sql-client.sh -l "file://${HOME}/
user-libs"
```

Optional: Set the result mode to tableau:

```
SET 'sql-client.execution.result-mode' = 'tableau';
```

Creating the Polaris catalog

Create a Polaris catalog:

```
CREATE CATALOG polaris WITH (
  'type' = 'iceberg',
  'catalog-type' = 'rest',
  'uri' = 'https://<polaris_host>:<polaris_port>/api/catalog',
  'credential' = '<polaris_client_id>:<polaris_client_secret>',
  'warehouse' = 's3_catalog',
```

```
'header.X-Iceberg-Access-Delegation' = 'vended-credentials',
'rest.auth.type' = 'oauth2',
'scope' = 'PRINCIPAL_ROLE:ALL'
);
```

Defining tables

Let us create the following 3 tables:

Source table to consume records from a Data Fabric Streams topic:

```
CREATE TABLE kafka_input_employees (
  id INT,
  name VARCHAR,
  department_id INT
) WITH (
  'connector' = 'kafka',
  'format' = 'csv',
  'topic' = '/user/mapruser1/s:input_employees',
  'properties.bootstrap.servers' = 'fake:9092',
  'properties.group.id' = 'group1',
  'scan.startup.mode' = 'earliest-offset'
);
```

A sink table to produce records to another Data Fabric Streams topic:

```
CREATE TABLE kafka_output_employees (
  id INT,
  name VARCHAR,
  department_id INT
) WITH (
  'connector' = 'kafka',
  'format' = 'csv',
  'topic' = '/user/mapruser1/s:output_employees',
  'properties.bootstrap.servers' = 'fake:9092'
);
```

A table representing an Iceberg table for both sourcing and sinking:

```
CREATE TABLE polaris.demospace.employees (
  id INT,
  name VARCHAR,
  department_id INT
);
```

Reading from a Data Fabric Streams topic

Query the source table to view records from the Data Fabric Streams topic:

```
SELECT * FROM kafka_input_employees;
```

This is a continuous query that runs in the foreground, until you press ^C.

Following is the sample result of the query:

```
+-----+-----+-----+-----+
| op |          id |          name | department_id |
+-----+-----+-----+-----+
| +I |          0 |        Alice |          0 |
```

Piping data from Data Fabric Streams to Iceberg

To pipe data from a DF Streams topic into an Iceberg table, use the `INSERT INTO ... SELECT FROM` query:

```
INSERT INTO polaris.demospace.employees
  SELECT * FROM kafka_input_employees;
```

This is a continuous query and it will go in background and run infinitely until stopped explicitly.

Reading from an Iceberg table

To verify the result, query the Iceberg table:

```
SELECT * FROM polaris.demospace.employees;
```

Following is the result:

```
+-----+-----+-----+-----+
| op |          id |          name | department_id |
+-----+-----+-----+-----+
| +I |          0 |        Alice |          0 |
+-----+-----+-----+-----+
```

If you have DEP Spark integrated with the same DEP Polaris instance, you should also be able to query the table there:

```
spark.sql("SELECT * FROM spark_demo.demospace.employees").show()
```

Following is the sample result:

```
+---+-----+-----+
| id| name|department_id|
+---+-----+-----+
|  0|Alice|          0|
+---+-----+-----+
```

Dumping data from Iceberg to Data Fabric Streams

Insert data from the Iceberg table into the Data Fabric Streams topic:

```
INSERT INTO kafka_output_employees
  SELECT * FROM polaris.demospace.employees;
```

Consuming the output topic

To verify the load, consume from the output topic:

```
/opt/mapr/kafka/kafka-3.6.1/bin/
kafka-console-consumer.sh --from-beginning --topic /user/mapruser1/
s:output_employees
```

The query output or result would be as follows:

```
0,Alice,0
```

Hadoop

Starting from release 6.2.0, Hadoop (YARN) is decoupled from the core platform and exists as an ecosystem component as part of EEP. This is an essential requirement to support multi-tenant computer clusters for the HPE Data Fabric. For more information about YARN, see [YARN](#) on page 5532.

HBase

Apache HBase™ is the Hadoop database, a distributed, scalable, big data store. You can use Apache HBase when you need random, realtime read-write access to your Big Data. This section describes how to use HBase with the HPE Data Fabric, but does not duplicate Apache documentation.

The goal of Apache HBase is to host very large tables – billions of rows with millions of columns – atop clusters of commodity hardware. Apache HBase is an open-source, distributed, versioned, column-oriented store modeled after Google's Bigtable: A Distributed Storage System for Structured Data by Chang et al. Just as Bigtable leverages the distributed data storage provided by the Google File System, Apache HBase provides Bigtable-like capabilities on top of Hadoop and Hadoop-compatible filesystems, such as the file system.

Installing Apache HBase on a Data Fabric cluster involves storing all HBase components in a single volume mapped to directory /hbase in the cluster. Tables are stored in a flat namespace, not grouped logically with related files. Because all Apache HBase data resides in one volume, only one set of storage policies can be applied to the entire Apache HBase datastore. Mirrors and snapshots of the HBase volume do not provide functional replication of the datastore. Despite this limitation, mirrors can be used to back up HLogs and HFiles in order to provide a recovery point for Apache HBase data.

This section documents how to work with HBase on the HPE Data Fabric. You can refer also to documentation available from the [Apache HBase project](#).

NOTE: The HPE Data Fabric Database provides native storage for table data, compatible with the HBase API. For new applications, consider using HPE Data Fabric Database binary tables for increased performance, more versatile table operations, and easier cluster administration.

Configuring HBase

Configure MapR-SASL Security (Authentication and Encryption) for HBase

This section describes the manual method for configuring security in HBase.

Starting with EEP 6.3.0, HBase services are secured by default with MapR-SASL. After installing HBase, you configure it by running the \$MAPR_HOME/server/configure.sh script with the -R option. There are two methods to configure HBase to be secure by default:

- Automatic Method
- Manual Method

Automatic Method

If you installed HBase by using the MapR Installer, the MapR Installer configures HBase daemons during installation. Additional configuration is not required.

Manual Method

After a new manual installation, to generate a valid default ecosystem configuration, run:

```
$MAPR_HOME/server/configure.sh -R
```

Four HBase services require configuration:

- HBase Master
- HBase RegionServer
- HBase Thrift
- HBase REST

Each service can be configured for authentication and encryption, as shown later on this page:

HBase Master and RegionServer

The Master and RegionServer services require the same configuration for security.

Authentication

To enable MapR-SASL authentication, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.security.authentication</name>
  <value>maprsasl</value>
</property>
```

Encryption

To enable MapR-SASL encryption, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.rpc.protection</name>
  <value>privacy</value>
</property>
```

Possible values for the `hbase.rpc.protection` property are:

- authentication (auth)
- integrity (auth-int)
- privacy (auth-conf)

The best practice is to spell out the values (authentication/integrity/privacy). The abbreviated values (in parentheses) can work, but using them is not recommended. Encryption is enabled only for the highest level of security (privacy).

HBase Thrift

It is possible to configure the HBase Thrift service to work over sockets or over the HTTP protocol. For authentication purposes, configuration is the same for both cases. For encryption, configuration is different for each case. Note that starting with the EEP6.3.0 property, `hbase.thrift.security.authentication` is no longer used to configure HBase Thrift for authentication.

Authentication

HBase Thrift relies on the same property used for Master and RegionServer. To enable authentication, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.security.authentication</name>
```

```
<value>maprsasl</value>
</property>
```

Encryption for Thrift over Sockets

To enable encryption with MapR-SASL for Thrift over sockets, make sure that the `hbase.regionserver.thrift.http` property is set to `false` and the following property is present in the `hbase-site.xml` file:

```
<property>
  <name>hbase.thrift.security.qop</name>
  <value>auth-conf</value>
</property>
```

Possible values for `hbase.thrift.security.qop` are:

- `auth`
- `auth-int`
- `auth-conf`

Encryption is enabled only for the highest level of security (`auth-conf`).

Encryption for Thrift over HTTP

To enable Thrift to work over the HTTP protocol, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.regionserver.thrift.http</name>
  <value>true</value>
</property>
```

To enable Thrift over HTTP encryption through SSL, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.thrift.ssl.enabled</name>
  <value>true</value>
</property>
```

HBase REST

Authentication

To enable HBase REST authentication, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.rest.authentication.type</name>

  <value>org.apache.hadoop.security.authentication.server.MultiMechsAuthenticat
  ionHandler</value>
</property>
```

With the `MultiMechsAuthenticationHandler`, MapR-SASL, Kerberos, and PAM authentication headers are supported. A custom `AuthenticationHandler` could be implemented and specified with the full class name in this property.

Encryption

To enable HBase REST SSL encryption, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.rest.ssl.enabled</name>
  <value>true</value>
</property>
```

HBase Services Web UIs

Web UIs are available for each HBase service. The Web UIs run simultaneously with the service and within the same process. Security for these UIs must be configured too.

Authentication

To enable HBase Web UI authentication, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.security.authentication</name>
  <value>maprsasl</value>
</property>
```

Authentication is implemented through the `MultiMechsAuthenticationHandler` and therefore supports MapR-SASL, Kerberos, and PAM authentication headers.

Encryption

To enable HBase Web UI SSL encryption, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.ssl.enabled</name>
  <value>true</value>
</property>
```

Configure HBase to use Kerberos

HBase supports MapR-SASL and Kerberos security, and can run securely independently of the security status of your HPE Data Fabric cluster.

Procedure

To configure HBase to use Kerberos, perform the following steps:

1. Install the `mapr-hbase-master` and `mapr-hbase-regionserver` packages on the cluster.
2. On all HBase nodes, perform the following steps:
 - a) Install the `krb5` packages and configure the Kerberos client as per the configuration for your environment.
 - b) Set up the HBase Kerberos principal `mapr/<fqdn>@<realm>`. Each node requires a unique keytab file and Kerberos identity.
 - c) Create an `hbase.keytab` file with the HBase Kerberos principal with the [same process](#) used to generate the CLDB keytab.
 - d) Copy the `hbase.keytab` file to the `/opt/mapr/conf` directory.
 - e) Use the `chown` command to change the keytab file's ownership to `mapr:mapr`.
 - f) Use the `chmod` command to set the file's permissions to `600`.

- g) Update the `hbase-site.xml` file by adding the following section:

```
<property>
  <name>hbase.security.authentication</name>
  <value>kerberos</value>
</property>
<property>
  <name>hbase.security.authorization</name>
  <value>true</value>
</property>
<property>
  <name>hbase.regionserver.kerberos.principal</name>
  <value>mapr/_HOST@<KERBEROS_REALM></value>
</property>
<property>
  <name>hbase.master.kerberos.principal</name>
  <value>mapr/_HOST@<KERBEROS_REALM></value>
</property>
```

- h) On a HPE Data Fabric cluster with security features enabled, replace the `{SIMPLE_LOGIN_OPTS}` value of the `MAPR_HBASE_SERVER_OPTS` property with `{KERBEROS_LOGIN_OPTS}` and the value of the `MAPR_HBASE_CLIENT_OPTS` property with `{HYBRID_LOGIN_OPTS}`. Also remove the `-Dzookeeper.sasl.client=false` option from the definition of `MAPR_HBASE_CLIENT_OPTS`.

These properties are located in the `/opt/mapr/conf/env.sh` file.

- i) On a HPE Data Fabric cluster with security features disabled, replace the `{SIMPLE_LOGIN_OPTS}` value of the `MAPR_HBASE_SERVER_OPTS` and `MAPR_HBASE_CLIENT_OPTS` properties in the `/opt/mapr/conf/env.sh` file with `{KERBEROS_LOGIN_OPTS}`.

3. On all HBase regionserver nodes, update the `hbase-site.xml` file by adding the following section:

```
<property>
  <name>hbase.regionserver.keytab.file</name>
  <value>/opt/mapr/conf/hbase.keytab</value>
</property>
<property>
  <name>hbase.coprocessor.region.classes</name>
  <value>org.apache.hadoop.hbase.security.token.TokenProvider,org.apache.hadoop.hbase.security.access.AccessController</value>
</property>
```

4. On the HBase master node, update the `hbase-site.xml` file by adding the following section:

```
<property>
  <name>hbase.master.keytab.file</name>
  <value>/opt/mapr/conf/hbase.keytab</value>
</property>
<property>
  <name>hbase.coprocessor.master.classes</name>
  <value>org.apache.hadoop.hbase.security.access.AccessController</value>
</property>
```

5. Restart the HBase master and regionserver nodes.

Enable Impersonation for HBase

About this task

HBase can be configured to offer impersonation, with or without Kerberos. This means that users can send commands to HBase through Hue without losing the fact that they will be run under their own credentials, instead of the hue user.

For instructions, see [Enable Impersonation for HBase Thrift1 Gateway](#).

Configure HBase ACLs

HBase supports Access Control Lists (ACLs) to limit the privileges of users on the system. Before you can use ACLs, you need to perform the steps to enable ACLs.

HBase ACLs support the following privileges:

- Read
- Write
- Execute
- Create tables
- Administrator

The possible scopes are:

- Superuser
- Global
- Namespace
- Table
- ColumnFamily
- Cell

For information about each scope, see [Understanding Access Levels](#).

Once you enable the use of ACLs, you can grant and remove privileges from users by using the grant and revoke commands from the HBase shell. The following example grants user jfoo read privileges from column family cf1 of table mytable:

```
hbase(main):001:0> grant 'jfoo' 'R' 'mytable','cf1'
```

This example removes user kbar's administrative privileges on the cluster:

```
hbase(main):001:0> revoke 'kbar' 'A'
```

Enable HBase Access Control

The following steps explain how to enable HBase ACLs.

Procedure

1. On the HBase Region Server, edit the `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml` file, and add the following section:

```
<property>
  <name>hbase.coprocessor.region.classes</name>

  <value>org.apache.hadoop.hbase.security.token.TokenProvider,org.apache.ha
doop.hbase.security.access.AccessController</value>
</property>
<property>
  <name>hbase.superuser</name>
  <value><admin1>,<admin2>,<group1>,...</value> <!-- group names are
prefixed with '@' -->
</property>
```

2. On the HBase Master, edit the `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml` file, and add the following section:

```
<property>
  <name>hbase.coprocessor.master.classes</name>
  <value>org.apache.hadoop.hbase.security.access.AccessController</
value>
</property>
<property>
  <name>hbase.superuser</name>
  <value><admin1>,<admin2>,<group1>,...</value> <!-- group names are
prefixed with '@' -->
</property>
```

3. Restart HBase on every node.

Set Up Compression with HBase

Using compression with HBase reduces the number of bytes transmitted over the network and stored on disk. These benefits often outweigh the performance cost of compressing the data on every write and uncompressing it on every read.

GZip Compression

GZip compression is included with most Linux distributions and works natively with HBase. To use GZip compression, specify it in the per-column family compression flag while creating tables in HBase shell. For example:

```
create 'mytable', {NAME=>'colfam', COMPRESSION=>'gz'}
```

LZ4 Compression

The LZ4 algorithm gives a slightly worse compression ratio than the LZO algorithm – which in turn is worse than algorithms like DEFLATE. However, compression speeds are similar to LZO and several times faster than DEFLATE, while decompression speeds can be significantly higher than LZO. Here is an example of configuring LZ4 compression:

```
create 'mytable1', {NAME=>'colfam', COMPRESSION=>'lz4'}
```

Snappy Compression

The Snappy compression algorithm is optimized for speed over compression. Snappy compression is included in the core Data Fabric installation, and no additional configuration is required.

Configure the Default Database for HBase Clients

For HBase version 1.1 and later, a default database configuration determines whether clients connect to HBase tables or HPE Data Fabric Database tables. You can change the default setting for all HBase clients, or you can set the database for a particular job. This setting is ignored for HBase 0.98.12 client connections.

Set the Default Database using `configure.sh`

About this task

`configure.sh` automatically sets the default database for a node based on the presence of the following `mapr` packages:

- `mapr-hbase-master`
- `mapr-hbase-regionserver`

`configure.sh` also provides a parameter that you can use to set the default database. To explicitly set the default database to either `maprdb` or `hbase`, run `configure.sh` with the `-defaultdb` parameter. For example:

```
configure.sh -R -defaultdb maprdb
```

The following table describes the effect of various `configure.sh` commands on the default database setting:

Table

If ...	And you run <code>configure.sh</code> with the following <code>-defaultdb</code> parameter ...		
	No <code>-defaultdb</code> parameter specified	<code>-defaultdb hbase</code>	<code>-defaultdb maprdb</code>
<code>hbasemaster</code> or <code>hbaseregionserver</code> is installed on a node	The default database is set to <code>hbase</code> .	The default database is set to <code>hbase</code>	The default database is set to <code>hbase</code> , and the <code>maprdb</code> setting is ignored.
<code>hbasemaster</code> and <code>hbaseregionserver</code> are NOT installed on a node	The default database is set to <code>maprdb</code> .	The default database is set to <code>hbase</code> . However, this configuration does not work because HBase is not running.	The default database is set to <code>maprdb</code> .

For more information about `configure.sh`, see [configure.sh](#) on page 3186.

Set the Default Database using `hbase-site.xml`

About this task

You can configure the `mapr.hbase.default.db` property in the `hbase-site.xml` to override the default database that is set for the cluster:

Procedure

1. In the `hbase-site.xml`, edit the default value of `mapr.hbase.default.db`, and set it to either `hbase` or `maprdb`.

For example:

```
<property>
  <name>mapr.hbase.default.db</name>
  <value>hbase</value>
</property>
```

2. Copy the property to the `hbase-site.xml` on each node that runs HBase, including any HBase client nodes.

Set the Database Type in the Job Configuration

Procedure

To set the database type in the job configuration you can add the following code:

- To connect to HPE Data Fabric Database tables:

```
Configuration conf = HBaseConfiguration.create();
conf.set("mapr.hbase.default.db", "maprdb");
Connection connection = ConnectionFactory.createConnection(conf);
Table table = connection.getTable(<TABLE_NAME>);
```

- To connect to HBase tables:

```
Configuration conf = HBaseConfiguration.create();
conf.set("mapr.hbase.default.db", "hbase");
Connection connection = ConnectionFactory.createConnection(conf);
Table table = connection.getTable(<TABLE_NAME>);
```

HBase Configuration Properties

This section describes and shows examples of the configuration properties used in the `hbase-site.xml` file.

Basic Properties**Hbase.rootdir**

Description: Specifies where the HBase data is stored. If not specified, by default HBase uses the `/tmp/` local folder. It is possible to use the local file system or a remote file system instance.

Example:

```
<property>
  <name>hbase.rootdir</name>
  <value>maprfs:///hbase</value>
</property>
```

HBase.cluster.distributed

Description: The mode the cluster will be in. Possible values are `false` for standalone mode and `true` for distributed mode. If `false`, startup runs all HBase and ZooKeeper daemons together in the one JVM.

Default: `false`.

Example:

```
<property>
  <name>hbase.cluster.distributed</
name>
  <value>true</value>
</property>
```

Hbase.zookeeper.quorum

Description: Comma-separated list of servers in the ZooKeeper ensemble. For example, host1.mydomain.com, host2.mydomain.com, host3.mydomain.com. By default this property is set to localhost for local and pseudo-distributed modes of operation. For a fully-distributed setup, this property should be set to a full list of ZooKeeper ensemble servers. If HBASE_MANAGES_ZK is set in hbase-env.sh, this is the list of servers that HBase will start or stop ZooKeeper on as part of cluster start or stop. Client-side, we will take this list of ensemble members and put it together with the hbase.zookeeper.property.clientPort config. and pass it into the Zookeeper constructor as the connectString parameter. Port could be specified together with hosts. In this case, the hbase.zookeeper.property.clientPort configuration is useless.

Example:

```
<property>
  <name>hbase.zookeeper.quorum</
name>
  <value>node11.cluster.com:5181</
value>
</property>
```

Dfs.support.append

Description: Specifies whether DFS allows appends to files.

Example:

```
<property>
  <name>dfs.support.append</name>
  <value>true</value>
</property>
```

Hbase.fsutil.maprfs.impl

Description: Specifies the FSUtil class (the utility methods for interacting with the underlying file system) used in HBase.

Example:

```
<property>
  <name>hbase.fsutil.maprfs.impl</
name>

  <value>org.apache.hadoop.hbase.util.FS
MapRUtils</value>
</property>
```

Hbase.regionserver.handler.count

Description: Sets the count of RPC Listener instances spun up on RegionServers. The same property is used by the Master for a count of master handlers. Too many handlers can be counter-productive. Make it a multiple of the CPU count. If mostly read-only, handlers count close to CPU count does well. Start with twice the CPU count and tune from there.
Default: 30.

Example:

```
<property>
  <name>hbase.regionserver.handler.count
</name>
  <value>30</value>
</property>
```

Fs.mapr.threads

Description: Controls currency in the HPE Data Fabric Database client.

Example:

```
<property>
  <name>fs.mapr.threads</name>
  <value>64</value>
</property>
```

Mapr.hbase.default.db

Description: Specifies whether to use HBase or the HPE Data Fabric Database client. Possible values are hbase and maprdb.

Example:

```
<property>
  <name>mapr.hbase.default.db</name>
  <value>hbase</value>
</property>
```

Security Properties

To support authorization, four properties must be enabled:

- hbase.security.authorization
- hbase.security.exec.permission.checks
- hbase.coprocessor.master.classes
- hbase.coprocessor.region.classes

If any one of them is missing, authorization will not be fully supported.

Hbase.security.authorizaation

Description: Specifies whether authorization is enabled or not.

Example:

```
<property>
  <name>hbase.security.authorization</
```

Hbase.security.exec.permission.checks

```
name>
  <value>true</value>
</property>
```

Description: Without this option, all users continue to have access to execute endpoint coprocessors. This option is not enabled when you enable HBase Secure Authorization for backward compatibility.

Example:

```
<property>

<name>hbase.security.exec.permission.c
hecks</name>
  <value>true</value>
</property>
```

hbase.coprocessor.master.classes

Description: A comma-separated list of coprocessors that are loaded by the master (MasterObserver coprocessors). The AccessController has to be active to support authorization.

Example:

```
<property>

<name>hbase.coprocessor.master.classes
</name>

<value>org.apache.hadoop.hbase.securit
y.access.
  AccessController</value>
</property>
```

Hbase.coprocessor.region.classes

Description: A comma-separated list of RegionObserver and Endpoint coprocessors. TokenProvider and AccessController must be active to support authorization.

Example:

```
<property>

<name>hbase.coprocessor.region.classes
</name>

<value>org.apache.hadoop.hbase.securit
y.token.TokenProvider.

org.apache.hadoop.hbase.security.acces
s.AccessController</value>
</property>
```

Authentication and Encryption Properties**hbase.security.authentication**

Description: Defines whether to use SASL mechanisms in HBase to authenticate RPC connections from clients to HBase Master and RegionServer. Also defines whether to support

authentication for HBaseThrift. Specifying `maprsasl` enables authentication for HBaseThrift over http.

Example:

```
<property>
  <name>hbase.security.authentication</name>
  <value>maprsasl</value>
</property>
```

hbase.security.token.authentication.method

Description: Enables [SCRAM](#) as a token authentication method. For FIPS-enabled nodes, running `/opt/mapr/server/configure.sh` automatically adds this property to `hbase-site.xml`. In clusters with a mix of FIPS and non-FIPS nodes, you must manually add this property to non-FIPS nodes.

Example:

```
<property>
  <name>hbase.security.token.authentication.method</name>
  <value>SCRAM-SHA-256</value>
</property>
```

hbase.rpc.protection

Description: Enables or disables transport security encryption. To support encryption, the `auth-conf` (privacy) value must be specified. Possible values are:

- `auth` or `authentication`
- `auth-int` or `integrity`
- `auth-conf` or `privacy`

Example:

```
<property>
  <name>hbase.rpc.protection</name>
  <value>auth-conf</value>
</property>
```

hbase.ssl.enabled

Description: Enables or disables SSL encryption for HBase WebUIs.

Example:

```
<property>
  <name>hbase.ssl.enabled</name>
  <value>true</value>
</property>
```

hbase.thrift.ssl.enabled

Description: Enables or disables SSL encryption for HBaseThrift. Works only for HBaseThrift over http (the `hbase.regionserver.thrift.http` property must be set to `true`).

Hbase.thrift.security.qop*Example:*

```
<property>
  <name>hbase.thrift.ssl.enabled</name>
  <value>true</value>
</property>
```

Description: Enables or disables transport security encryption for HBaseThrift. Use the auth-conf value to support encryption. This property works only for HBaseThrift over sockets (the hbase.regionserver.thrift.http property must be set to false). Possible values are:

- auth
- auth-int
- auth-conf

Example:

```
<property>
  <name>hbase.thrift.security.qop</name>
  <value>auth-conf</value>
</property>
```

hbase.rest.authentication.type

Description: Defines the AuthenticationHandler to use during user-to-HBaseRest authentication. The MultiMechsAuthenticationHandler supports PAM, MapR SASL, and Kerberos authentication. If this property is not specified, authentication for HBaseRest is disabled.

Example:

```
<property>

<name>hbase.rest.authentication.type</name>

<value>org.apache.hadoop.security.authentication.server.
    MultiMechsAuthenticationHandler</value>
</property>
```

hbase.rest.ssl.enabled

Description: Enables or disables SSL encryption (from client to server and vice versa) for the HBaseRest service.

Example:

```
<property>
  <name>hbase.rest.ssl.enabled</name>
  <value>true</value>
</property>
```

Impersonation Properties

hbase.thrift.support.proxyuser

Description: Enables or disables impersonation for HBaseThrift. Works only for thrift over http (the `hbase.regionserver.thrift.http` property must be set to true).

Example:

```
<property>
<name>hbase.thrift.support.proxyuser</name>
  <value>true</value>
</property>
```

hbase.rest.support.proxyuser

Description: Enables or disables impersonation for HBaseRest.

Example:

```
<property>
<name>hbase.rest.support.proxyuser</name>
  <value>true</value>
</property>
```

hbase.regionserver.thrift.http

Description: Defines whether to use HBaseThrift over http (if true is specified) or over sockets. Used to support impersonation for thrift over http.

Example:

```
<property>
<name>hbase.regionserver.thrift.http</name>
  <value>true</value>
</property>
```

Using HBase

This section includes the following topics about working with HBase:

Getting Started in HBase

About this task

In this section, we'll create an HBase table on the cluster, enter some data, query the table, then clean up the data and exit.

HBase tables are organized by column, rather than by row. Furthermore, the columns are organized in groups called *column families*. When creating an HBase table, you must define the column families before inserting any data. Column families should not be changed often, nor should there be too many of them,

so it is important to think carefully about what column families will be useful for your particular data. Each column family, however, can contain a very large number of columns. Columns are named using the format family:qualifier.

Unlike columns in a relational database, which reserve empty space for columns with no values, HBase columns simply don't exist for rows where they have no values. This not only saves space, but means that different rows need not have the same columns; you can use whatever columns you need for your data on a per-row basis.

Procedure

1. Start the HBase shell by typing the following command:

```
hbase shell
```

2. Create a table called weblog with one column family named stats:

```
create 'weblog', 'stats'
```

3. Verify the table creation by listing everything:

```
list
```

4. Add a test value to the daily column in the stats column family for row 1:

```
put 'weblog', 'row1', 'stats:daily', 'test-daily-value'
```

5. Add a test value to the weekly column in the stats column family for row 1:

```
put 'weblog', 'row1', 'stats:weekly', 'test-weekly-value'
```

6. Add a test value to the weekly column in the stats column family for row 2:

```
put 'weblog', 'row2', 'stats:weekly', 'test-weekly-value'
```

7. Type scan 'weblog' to display the contents of the table. Sample output:

```
ROW                COLUMN+CELL
 row1              column=stats:daily, timestamp=1321296699190,
 value=test-daily-value
 row1              column=stats:weekly, timestamp=1321296715892,
 value=test-weekly-value
 row2              column=stats:weekly, timestamp=1321296787444,
 value=test-weekly-value
2 row(s) in 0.0440 seconds
```

8. Type get 'weblog', 'row1' to display the contents of row 1. Sample output:

```
COLUMN            CELL
 stats:daily      timestamp=1321296699190, value=test-daily-value
 stats:weekly     timestamp=1321296715892, value=test-weekly-value
2 row(s) in 0.0330 seconds
```

9. Type `disable 'weblog'` to disable the table.
10. Type `drop 'weblog'` to drop the table and delete all data.
11. Type `exit` to exit the HBase shell.

Running MapReduce Jobs with HBase

About this task

To run MapReduce applications with data stored in HBase, use a command such as the following to export table data to the HPE Data Fabric file system:

```
$ hadoop jar /opt/mapr/hbase/hbase-1.1.13/lib/
hbase-server-1.1.13.0-mapr-1912.jar export t1 /user/mapr/t1
```

or

```
$ hbase org.apache.hadoop.hbase.mapreduce.Export t1 /user/mapr/t4
```

The result is the same because of the tools included in the `hbase-server.jar` file:

```
$ hadoop fs -ls /user/mapr/t1/
Found 2 items
-rwxr-xr-x    3 mapr mapr          0 2019-11-11 15:00 /user/mapr/t1/_SUCCESS
-rw-r--r--    3 mapr mapr      249 2019-11-11 15:00 /user/mapr/t1/
part-m-000000
$ hadoop fs -ls /user/mapr/t4/
Found 2 items
-rwxr-xr-x    3 mapr mapr          0 2019-11-11 15:09 /user/mapr/t4/_SUCCESS
-rw-r--r--    3 mapr mapr      249 2019-11-11 15:09 /user/mapr/t4/
part-m-000000
$
```

Following is an example of the full output:

```
$ hadoop jar /opt/mapr/hbase/hbase-1.1.13/lib/
hbase-server-1.1.13.0-mapr-1912.jar export t1 /user/mapr/t1

The following table shows the tools included in the hbase-server.jar:

Name ¹	Class ²	Description
rowcounter	RowCounter	Count rows in HBase table
CellCounter	CellCounter	Count cells in HBase table
export	Export	Write table data to HPE Data Fabric file system
import	Import	Import data written by Export
importtsv	ImportTsv	Import data in TSV format
completebulkload	LoadIncrementalHFiles	Complete a bulk data load
copytable	CopyTable	Export a table from local cluster to peer cluster
verifyrep	VerifyReplication	Compare the data from tables in two different clusters  NOTE: This function does not work for incrementColumnValues cells since the timestamp is changed after being appended to the log.
WALPlayer	WALPlayer	Replay WAL files
exportsnapshot	ExportSnapshot	Export the specific snapshot to a given file system

¹ Class is used for `hbase.org.apache.hadoop.hbase.mapreduce.<class>...`

² Name is used for `hadoop jar /opt/mapr/hbase/hbase-1.1.13/lib/hbase-server-1.1.13.0-mapr-1912.jar <name>...`

Using the libhbase Library

libhbase is a JNI-based, thread-safe C library that implements a native HBase client. You can use libhbase to build applications that access HBase.

This page contains the following topics:

- Installing libhbase
- Upgrading libhbase
- Building applications with libhbase
- Configuring the application environment
- Running a libhbase performance test

For examples that show how to use the APIs, see the [sample source file](#).

Installing libhbase

Install libhbase on the nodes from which you will build and run the application.

Complete the following steps to install libhbase from a repository:

1. Configure the repository to point to <http://package.ezmeral.hpe.com/releases/MEP/MEP-6.3.0/>.

IMPORTANT: To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see [Using the HPE Data Fabric Token-Authenticated Internet Repository](#) on page 153.

2. Based on your operating system, run one of the following commands to install the package:

- On Red Hat /Centos: `yum install mapr-libhbase`
- On SLES: `zypper install mapr-libhbase`
- On Ubuntu: `apt-get install mapr-libhbase`

Once the installation completes, the libhbase installation includes the following directories under `/opt/mapr/libhbase/libhbase-<version>`:

```
/
+---bin/
+---conf/
+---include/
|   +---hbase/
+---lib/
|   +---native/
+---src
    +---examples/
    |   +---async/
    +---test/
        +---native/
        +---common/
```

NOTE: The `include` folder contains the headers required to build applications. The `lib/native` directory contains shared libraries.

Upgrading libhbase

To upgrade to a more recent version of libhbase:

1. Install the new version.
2. Re-configure the application environment to refer to the new libraries.

Building Applications with libhbase

libhbase should be installed on each node that builds the application.

Note the following items when you build applications with libhbase:

- The headers required to build applications are located under `/opt/mapr/libhbase/libhbase-<version>/include`.
- libhbase shared library is located in the following directory: `/opt/mapr/libhbase/libhbase-<version>/lib/native`.
- Since libhbase uses JNI, you must also link your application against libjvm. In general, the libjvm library is located within the JDK/JRE installation directory.

For example, the following command builds the `hello_hbase` application with the `hello_hbase.c` source code:

```
gcc -o hello_hbase hello_hbase.c -I/opt/mapr/
libhbase/libhbase-0.98.7/include -L/opt/mapr/libhbase/libhbase-0.98.7/lib/
native -lhbase -L/usr/lib/jvm/java-7-sun/jre/lib/amd64/server -ljvm
```

Configuring the Application Environment

Complete the following steps to configure the node from which you run the application:

- Verify that libhbase is installed on the node.
- Verify that both the libhbase and libjvm shared libraries are in the application's library search path. The libhbase shared library is located under `/opt/mapr/libhbase/libhbase-<version>/lib/native`. In general, the libjvm library is located within the JDK/JRE installation directory.
- Specify any JARs required by the application with one of the following environment variables: `CLASSPATH` or `HBASE_LIB_DIR`.
- Specify custom JVM options, such as `-Xmx`, using the environment variable `LIBHBASE_OPTS`.

Running a libhbase Performance Test

libhbase 0.98.7 includes a performance test that supports sequential/random gets and puts. In libhbase 0.98.9, the performance test utility also includes support for Zipfian, support for uniform random key generation, and it test for scans. You can run the test using this [shell script](#).

HBase Client and HPE Data Fabric Database Binary Tables

HPE Data Fabric 6.0.x and 6.1 provide Apache HBase-compatible APIs and client interfaces but do not support HBase as an ecosystem component. HPE Data Fabric Database [binary tables](#) provide native storage for table data and include high performance and availability, versatile table operations, and streamlined cluster administration. The following APIs and tools are available for HPE Data Fabric Database binary tables:

HBase Client

- After installing the HBase Client, you can use HBase Shell commands to manipulate HPE Data Fabric Database binary tables on a remote machine. See [Installing HBase on a Client Node](#) on page 299 and [HPE Data Fabric Database HBase Shell \(Binary Tables\)](#) on page 7441.
- HPE Data Fabric Database supports binary tables through the `libMapRClient` (a library of C APIs) and Apache HBase Java APIs. See [Developing Applications for Binary Tables](#) on page 3648.

HBase REST Gateway

- The HBase REST Gateway allows users to manipulate HPE Data Fabric Database binary tables through the HBase REST API. See [Installing the HBase REST Gateway](#) on page 301.

HBase Thrift Gateway

- The HBase Thrift Gateway allows users to manipulate HPE Data Fabric Database binary tables through the HBase Thrift API. See [Installing the HBase Thrift Gateway](#) on page 301.

Using the HBase Thrift Gateway

HBase Thrift Gateway includes an API and a service that accepts Thrift requests to connect to HPE Data Fabric Database and HBase tables. The HBase Thrift Gateway is installed as a service that is managed by Warden. Installing `mapr-hbasethrift` adds the `warden.hbasethrift.conf` file to the `/opt/mapr/conf/conf.d` directory.

NOTE: MapR-SASL authentication, encryption, and impersonation for HBase Thrift Gateway are enabled by default on secure clusters.

Starting the HBase Thrift Service

About this task

To start the HBase thrift service, enter the following command with the name of the host where `hbasethrift` is running:

```
maprcli node services -name hbasethrift -action start -nodes <node_hostname>
```

Configure Kerberos for HBase Thrift Gateway

About this task

Procedure

1. Add the following to the `hbase-site.xml` file for every Thrift gateway:

```
<property>
  <name>hbase.thrift.keytab.file</name>
  <value>$KEYTAB</value>
</property>
<property>
  <name>hbase.thrift.kerberos.principal</name>
  <value>$USER/_HOST@HADOOP.LOCALDOMAIN</value>
  <!-- This may need to be HTTP/_HOST@<REALM> and _HOST may not work.
You may have to put the concrete full hostname. -->
</property>
<property>
  <name>hbase.thrift.security.qop</name>
  <value>auth-conf</value>
</property>
<!-- Add these if you need to configure a different DNS interface from
the default -->
<property>
  <name>hbase.thrift.dns.interface</name>
  <value>default</value>
</property>
<property>
  <name>hbase.thrift.dns.nameserver</name>
  <value>default</value>
</property>
```

Substitute the appropriate credential and keytab for `$USER` and `$KEYTAB` respectively.

2. If you are running HBase Thrift in HTTP mode, you must add additional properties to the `hbase-site.xml` to enable HTTP connections through Kerberos. This is required if you enabled the following property in the `hbase-site.xml`:

```
<property>
  <name>hbase.regionserver.thrift.http</name>
  <value>true</value>
</property>
```

Add the following properties to enable HTTP connections through Kerberos:

```
<property>
  <name>hbase.thrift.spnego.principal</name>
  <value>HTTP/_HOST@HADOOP.LOCALDOMAIN</value>
</property>
<property>
  <name>hbase.thrift.spnego.keytab.file</name>
  <value>$KEYTAB</value>
</property>
```

3. To use HPE Data Fabric Database tables without the full path, add the following property to the `core-site.xml` file:

```
<property>
  <name>hbase.table.namespace.mappings</name>
  <value>*:/</value>
</property>
```

Add this property **ONLY** if you are working with HPE Data Fabric Database tables. Working with HBase tables is not possible when this property is present. For more information, see [Considerations for Upgrading to HBase 1.1.13](#) on page 502. For more information about mapping tables, see [Mapping to HBase Table Namespaces](#) on page 423.

Results

The Thrift gateway authenticates with HBase using the supplied credential. No authentication is performed by the Thrift gateway itself. All client access via the Thrift gateway uses the Thrift gateway's credential and has its privilege.

Enable Impersonation for HBase Thrift Gateway

About this task

To configure the Thrift gateway to authenticate to HBase on the client's behalf, and to access HBase using a proxy user:

Procedure

1. To allow proxy users, add the following to the `hbase-site.xml` file for every HBase node:

```
<property>
  <name>hadoop.proxyuser.$USER.groups</name>
  <value>$GROUPS</value>
</property>
<property>
  <name>hadoop.proxyuser.$USER.hosts</name>
  <value>$GROUPS</value>
</property>
```

2. To enable the doAs feature, add the following to the `hbase-site.xml` file for every Thrift gateway:

```
<property>
  <name>hbase.regionserver.thrift.http</name>
  <value>true</value>
</property>
<property>
  <name>hbase.thrift.support.proxyuser</name>
  <value>true</value>
</property>
```

3. Restart the Thrift gateway processes for the changes to take effect. If a node is running Thrift, the output of the `jps` command will list a `ThriftServer` process.

- To restart Thrift on a node, use the following `maprccli` command:

```
maprccli node services -name hbasethrift -action restart -nodes
<node_hostname>
```

Using the HBase REST Gateway

HBase REST Gateway includes an API and a service that accepts REST requests to connect to HPE Data Fabric Database and HBase tables. Starting in version 0.98.9, the HBase REST Gateway is installed as a service that is managed by Warden. When `mapr-hbase-rest` is installed, the `warden.hbase-rest.conf` file is added to the `/opt/mapr/conf/conf.d` directory.

NOTE: PAM authentication, encryption, and impersonation for HBase REST are enabled by default on secure clusters.

Starting the HBase REST Service

About this task

To start the HBase REST service, enter the following command with the name of the host where `hbaserest` is running:

```
maprccli node services -name hbaserest -action start -nodes <node_hostname>
```

Configure Kerberos for HBase REST Gateway

About this task

Procedure

1. Add the following to the `hbase-site.xml` file for every REST Gateway:

```
<property>
  <name>hbase.rest.keytab.file</name>
  <value>$KEYTAB</value>
</property>
<property>
  <name>hbase.rest.kerberos.principal</name>
  <value>$USER/_HOST@HADOOP.LOCALDOMAIN</value>
</property>
```

Substitute the appropriate credential and keytab for `$USER` and `$KEYTAB` respectively.

The REST Gateway will authenticate with HBase using the supplied credential.

2. To enable REST Gateway Kerberos authentication for client access, add the following to the `hbase-site.xml` file for every REST Gateway:

```
<property>
  <name>hbase.rest.authentication.type</name>
  <value>kerberos</value>
</property>
<property>
  <name>hbase.rest.authentication.kerberos.principal</name>
  <value>HTTP/_HOST@HADOOP.LOCALDOMAIN</value>
</property>
<property>
  <name>hbase.rest.authentication.kerberos.keytab</name>
  <value>$KEYTAB</value>
</property>
<!-- Add these if you need to configure a different DNS interface from
the default -->
<property>
  <name>hbase.rest.dns.interface</name>
  <value>default</value>
</property>
<property>
  <name>hbase.rest.dns.nameserver</name>
  <value>default</value>
</property>
```

Substitute the keytab for HTTP for \$KEYTAB.

Enable Impersonation for HBase REST Gateway

About this task

To enable HBase REST Gateway impersonation, configure all HBase servers to allow proxy users, then configure every REST Gateway to enable impersonation.

Procedure

- To enable REST Gateway impersonation, add the following to the `hbase-site.xml` file for every REST gateway:

```
<property>
  <name>hbase.rest.support.proxyuser</name>
  <value>true</value>
</property>
```

HBase REST Gateway and HBase Thrift Gateway Secured By Default to Use SSL

Starting in EEP 6.0.0, HBase REST and HBase Thrift use SSL by default on secured clusters.

1. On a secure cluster, by default, HBase REST and HBase Thrift read the `ssl-client.xml` file and configure SSL using this file.

2. To enable HBase REST and Thrift encryption, use the following properties. Note that SSL for Thrift is enabled only when the `hbase.regionserver.thrift.http` property is `true`:

Enabling HBase REST encryption

```
<property>
  <name>hbase.rest.ssl.enabled</name>
  <value>true</value>
</property>
```

Enabling HBase Thrift encryption

```
<property>
  <name>hbase.thrift.ssl.enabled</name>
  <value>true</value>
</property>
```

HCatalog

HCatalog is a table and storage management layer for Hadoop that enables users with different data processing tools — Pig, MapReduce — to more easily read and write data on the grid. HCatalog's table abstraction presents users with a relational view of data in the Hadoop distributed filesystem (HDFS) and ensures that users need not worry about where or in what format their data is stored — RCFile format, text files, SequenceFiles, or ORC files.

HCatalog supports reading and writing files in any format for which a SerDe (serializer-deserializer) can be written. By default, HCatalog supports RCFile, CSV, JSON, and SequenceFile, and ORC file formats. To use a custom format, you must provide the InputFormat, OutputFormat, and SerDe.

HCatalog is also automatically installed and upgraded along with Hive. For information about using HCatalog with Hive, see [Hive and WebHCat Integration](#) and [Hive and HCatalog Integration](#).

Hive

Apache Hive™ is a data warehouse system for Hadoop that facilitates easy data summarization, ad-hoc queries, and the analysis of large datasets stored in Hadoop-compatible file systems, such as HPE Data Fabric. Hive provides a mechanism to project structure onto this data and query the data using a SQL-like language called HiveQL. At the same time this language also allows traditional map/reduce programmers to plug in their custom mappers and reducers when it is inconvenient or inefficient to express this logic in HiveQL.

You can refer also to documentation available from the [Apache Hive project](#).

Hive components include the following:

- Hive Metastore
- HiveServer2
- HCatalog
- WebHCat
- Hive CLI
- Beeline

NOTE: If you installed Hive using the installer with the "Enable Security" check box selected, Hive is secured and no further configuration is required. However, if you installed Hive manually and wish to enable security for Hive, see [Hive Security Configuration Options](#) on page 4959 for information.

IMPORTANT: HPE strongly recommends that all deprecated Hive functions, whether they have been deprecated by the Apache community or by HPE, are not to be used in production environments. These functions are unstable and are no longer maintained.

The following examples show how these components communicate with each other and when you might want to configure security features such as authentication and encryption:

Case 1: Jobs Submitted by the Hive CLI, Embedded Metastore

In this case, all the information needed by Hive is contained within a single process, and no security is needed beyond that already provided by the JobClient's communications.

Case 2: Jobs Submitted by the Hive CLI, Remote Metastore

In this case, Hive needs to access a metastore remote to Hive's process using a Thrift interface. This communication can be left secured with Kerberos, or secured with MapR-SASL.

Case 3: Jobs Submitted by HiveServer2, Embedded Metastore

In this case, JDBC or ODBC on a user's machine sends queries to HiveServer2, which submits the queries to the driver for parsing. The communication between JDBC and HiveServer2 can be secured with username and password with SSL, MapR-SASL, or with Kerberos. Either approach offers authentication and encryption. JDBC/ODBC can also be configured to use username and password without SSL, which offers authentication *only*.

To use SSL from a client machine the `ssl_truststore` file must be copied from the cluster to the client.

Case 4: Jobs Submitted by HiveServer2, Remote Metastore

In this case, JDBC or ODBC on a user's machine sends queries to HiveServer2, which submits the queries to the driver, which runs the query and returns the results. The metastore is remote. In this case, there are two communications links to secure: the Thrift interface between the metastore client and server, and the Thrift interface between the client JDBC/ODBC and HiveServer2. The security arrangements for these links are identical to Cases 2 and 3.

Getting Started with Hive

About this task

In this tutorial, you'll create a Hive table, load data from a tab-delimited text file, and run a couple of basic queries against the table. For details on setting up HiveServer2 and starting BeeLine, see [Using JDBC or Beeline to Connect to HiveServer2](#) on page 5056.

NOTE: If you are using HiveServer2, you will use the BeeLine CLI instead of the Hive shell, as shown below.

Take a look at the source data

About this task

First, take a look at the contents of the file using the terminal:

Procedure

1. Save the following data to a text file named `sample-table.txt`:

The `sample-table.txt` table columns are delimited by tabs:

```

1320352532    1001    http://www.mapr.com/doc    http://www.mapr.com
192.168.10.1
1320352533    1002    http://www.mapr.com    http://www.example.com
192.168.10.10
1320352546    1001    http://www.mapr.com    http://www.mapr.com/doc
192.168.10.1

```

If you are working on the Data Fabric Virtual Machine, we'll be loading the file from the Virtual Machine's local filesystem (not the cluster storage layer), so save the file in the Home directory (for example, `/home/mapr`).

2. Make sure you are in the Home directory where you saved `sample-table.txt` (type `cd ~` if you are not sure).
3. Type `cat sample-table.txt` to display the following output.

Results

```
mapr@mapr-desktop:~$ cat sample-table.txt
1320352532    1001    http://www.mapr.com/doc    http://www.mapr.com
192.168.10.1
1320352533    1002    http://www.mapr.com    http://www.example.com
192.168.10.10
1320352546    1001    http://www.mapr.com    http://www.mapr.com/doc
192.168.10.1
```

Notice that the file consists of only three lines, each of which contains a row of data fields separated by the TAB character. The data in the file represents a web log.

Create a table in Hive and load the source data:

Procedure

1. Type the following command to start the Hive shell, using tab-completion to expand the `<version>`:

```
/opt/mapr/hive/hive-<version>/bin/hive
```

2. At the `hive>` prompt, type the following command to create the table:

```
CREATE TABLE web_log(viewTime INT, userid BIGINT, url STRING, referrer
STRING, ip STRING) ROW FORMAT DELIMITED FIELDS TERMINATED BY '\t';
```

3. Type the following command to load the data from `sample-table.txt` into the table:

```
LOAD DATA LOCAL INPATH '/home/mapr/sample-table.txt' INTO TABLE web_log;
```

Run basic queries against the table

Procedure

- Try the simplest query, one that displays all the data in the table:

```
SELECT web_log.* FROM web_log;
```

This query would be inadvisable with a large table, but with the small sample table it returns very quickly.

- Try a simple `SELECT` to extract only data that matches a desired string:

```
SELECT web_log.* FROM web_log WHERE web_log.url LIKE '%doc';
```

This query launches a MapReduce application to filter the data.

Configuring Hive

This section contains the following topics:

Configure Hive Directories

You can configure the following Hive directories:

- Hive Scratch Directory
- Hive Warehouse Directory
- Hive Error Logs Directory

Hive Scratch Directory

In Hive 1.0, HPE Data Fabric configures the Hive scratch directory to be `/user/<user.name>/tmp/hive/<user.name>`. In Hive 0.13, the default scratch directory is `/user/<user.name>/tmp/hive`. The hive user must have write access to the `/user` folder.

To modify this parameter, perform one of the following operations:

- Set this parameter in the `hive-site.xml`. Copy the `hive.exec.scratchdir` property elements from the `$HIVE_HOME/conf/hive-default.xml.template` file and paste them into an XML configuration element in the `$HIVE_HOME/conf/hive-site.xml` file. Then, modify the value elements for these directories in the `hive-site.xml` file.
- Set this parameter from the Hive shell. Example:

```
hive> set hive.exec.scratchdir=/myvolume/tmp
```

NOTE: You will see better performance when queries import data from a table that is in the same Data Fabric volume as Hive scratch directory.

How Hive Handles Scratch Directories on HPE Data Fabric

When a query requires Hive to query existing tables and create data for new tables, Hive uses the following workflow:

1. Create the query scratch directory `hive_<timestamp>_<randomnumber>` under the Hive scratch directory.
2. Create the following directories as subdirectories of the scratch directory:
 - a. Final query output directory. This directory's name takes the form `-ext-<number>`.
 - b. An output directory for each MapReduce application. These directories' names take the form `-mr-<number>`.
3. Hive executes the tasks, including MapReduce applications and loading data to the query output directory.
4. Hive loads the data from output directory into a table. By default, the table's directory is in the `/user/hive/warehouse` directory. You can configure this location with the `hive.metastore.warehouse.dir` parameter in `hive-site.xml`, unless the table DDL specifies a custom location. Hive renames the output directory to the table directory in order to load the output data to the table.
5. The scratch directories are automatically deleted after the query completes successfully.

HPE Data Fabric uses [Administering Volumes](#) on page 1429, which are logical units that enable you to apply policies to a set of files, directories, and sub-volumes. When the output directory and the table directory are in different volumes, this workflow involves moving data across volumes. Moving

data across volumes is slower than moving data within a volume. Therefore, HPE Data Fabric sets `hive.optimize.insert.dest.volume` to `true` to automatically create a scratch directory in the same volume as the target table.

Hive Warehouse Directory

Hive tables are stored in the Hive warehouse directory. By default, HPE Data Fabric configures the Hive warehouse directory to be `/user/hive/warehouse` under the root volume. This default is defined in the `$HIVE_HOME/conf/hive-default.xml.template` file.

To modify this parameter, perform one of the following operations:

- Set this parameter in the `hive-site.xml`. Copy the `hive.metastore.warehouse.dir` property elements from the `$HIVE_HOME/conf/hive-default.xml.template` file and paste them into an XML configuration element in the `$HIVE_HOME/conf/hive-site.xml` file. Then, modify the value elements for these directories in the `hive-site.xml` file.
- Set this parameter from the Hive shell. Example:

```
hive> set hive.metastore.warehouse.dir=/myvolume/mydirectory
```

NOTE: You will see better performance when queries move data between tables in the same volume.

Hive Error Logs Directory

The log files are stored in `/opt/mapr/hive/hive-<version>/logs/<user>` by default.

To modify the log location:

1. Configure `hive.log.dir` in `$HIVE_HOME/conf/hive-log4j.properties` file. Example:

```
hive.log.dir=<other_location>
```

2. Set the sticky bit on the new directory. Example:

```
chmod 1777 <other_location>
```

Configuring Hive Client on a Data Fabric Client Node

This topic describes how to configure the Hive client on a Data Fabric client node.

Installing Hive on a Client Node

Prerequisites

The following instructions use the package manager to download and install Hive from the DEP / EEP repository to a client node. When you install Hive on a client node, you can use the Hive shell from a machine outside the cluster.

Before you begin, verify the following prerequisites:

- The DEP / EEP repository is set up. To set up the DEP / EEP repository, see [Step 11: Install Ecosystem Components Manually](#) on page 284.
- The HPE Data Fabric client must be installed on the same node that you install the Hive client.
For HPE Data Fabric client setup instructions, see [HPE Data Fabric Client](#) on page 360.
- You must know the IP addresses or hostnames of the ZooKeeper nodes on the cluster.

About this task

Run the following commands as root or using sudo.

Procedure

1. On the client computer, install `mapr-hive` package.

CentOS or Red Hat:

```
yum install mapr-hive
```

Ubuntu

```
apt-get install mapr-hive
```

SLES

```
zypper install mapr-hive
```

2. Copy `hive-site.xml` from the cluster node to the client node (replace `hive-site.xml` after the installation is complete).
3. Finish the configuration procedure by running [configure.sh](#) on page 3186 with the `-R` flag specified.
4. Example of a connection string for a MapR-secure cluster:

```
/opt/mapr/hive/hive-3.1.3/bin/beeline -u "jdbc:hive2://  
<HS2_SERVER_CLUSTER_FQDN>:10000/default;auth=maprsasl;ssl=true"
```

Configuring MSCK REPAIR TABLE

This section guides you through configuring `MSCK REPAIR TABLE` command to compare and update the partitions in Hive Metastore and file systems.

Use the `MSCK REPAIR TABLE` command to manually update (ADD, DROP, SYNC) the partitions on Hive metastore with respect to file systems like HDFS, Amazon S3, filesystem, and others.

For example: You specify the location of filesystem when you create a Hive table. When you add or delete the partitions to or from the filesystem, the partitions in filesystem and Hive metastore becomes inconsistent.

Run `MSCK REPAIR TABLE` command to compare the partitions in filesystem and the partitions in Hive metastore and update the partitions in Hive metastore.

```
MSCK [REPAIR] TABLE <table name> [ADD/DROP/SYNC PARTITIONS];
```

Configure the Hive Metastore with the following Hive property:

Property	Default	Description
hive.msck.repair.batch.max.retries	0	Maximum number of retries for the msck repair command when adding unknown partitions. If the value is greater than zero it will retry adding unknown partitions until the maximum number of attempts is reached or batch size is reduced to 0, whichever is earlier. In each retry attempt, it will reduce the batch size by a factor of 2 until it reaches zero. If the value is set to zero it will retry until the batch size becomes zero as described above.

Configuring Database for Hive Metastore

The metadata for Hive tables and partitions are stored in the Hive Metastore. By default, the Hive Metastore stores all Hive metadata in an embedded Apache Derby database in the file system. The following sections describe how to configure other DBs for Hive Metastore.

CAUTION: Do not use `datanucleus.schema.autoCreateAll` for populating underlying databases. For more details, see [prohibited usage of datanucleus.schema.autoCreateAll property](#).

Use MySQL for the Hive Metastore

The metadata for Hive tables and partitions are stored in the Hive Metastore. By default, the Hive Metastore stores all Hive metadata in an embedded Apache Derby database in the HPE Data Fabric file system. Derby only allows one connection at a time; if you want multiple concurrent Hive sessions, you can use MySQL for the Hive Metastore.

Prerequisites

Review the following prerequisites before you begin:

- Verify that MySQL (version 5.6.17 or later) is installed on the machine that will host the Hive metastore, and also verify that you can connect to the MySQL server from the Hive machine. You can run the Hive metastore on any machine that is accessible from Hive. You can test this with the following command:

```
mysql -h <hostname> -u <user>
```

- The database administrator must create a database for the Hive metastore data, and the username specified in `javax.jdo.option.ConnectionUserName` must have permissions to access it. The database can be specified using the `ConnectionURL` parameter. The tables and schemas are created automatically when the metastore is first started.

TIP: In MapR 6.1.0 and earlier releases, the following steps can be used interchangeably for MariaDB.

About this task

Complete the following steps to configure Hive to use MySQL for the Hive Metastore:

IMPORTANT: For [MySQL 8](#), set the `javax.jdo.option.ConnectionDriverName` property to `com.mysql.cj.jdbc.Driver`. The `com.mysql.jdbc.Driver` is deprecated. The new driver class is `com.mysql.cj.jdbc.Driver`. However, the driver is automatically registered via the Service Provider Interface, so manual loading of the driver class is generally unnecessary.

Procedure

1. Update the `hive-site.xml` in the Hive configuration directory (`/opt/mapr/hive/hive-<version>/conf`) with the following contents:

```
<configuration>

  <property>
    <name>javax.jdo.option.ConnectionURL</name>
    <value>jdbc:mysql://localhost:3306/hive?
createDatabaseIfNotExist=true</value>
    <description>JDBC connect string for a JDBC metastore</description>
  </property>

  <property>
    <name>javax.jdo.option.ConnectionDriverName</name>
    <value>com.mysql.jdbc.Driver</value>
    <description>Driver class name for a JDBC metastore</description>
  </property>

  <property>
    <name>javax.jdo.option.ConnectionUserName</name>
    <value>root</value>
    <description>username to use against metastore database</description>
  </property>

  <property>
    <name>javax.jdo.option.ConnectionPassword</name>
    <value><fill in with password></value>
    <description>password to use against metastore database</description>
  </property>

  <property>
    <name>hive.metastore.uris</name>
    <value>thrift://localhost:9083</value>
  </property>

</configuration>
```

2. Run the `schematool` command as an initialization step.

```
/opt/mapr/hive/hive-<version>/bin/schematool -dbType mysql -initSchema
```

3. To connect to an existing MySQL metastore, make sure the `ConnectionURL` parameter and the `Thrift URIs` parameters in `hive-site.xml` point to the metastore's host and port.
4. To set a specific port for Thrift URIs, add the command `export METASTORE_PORT=<port>` into the file `hive-env.sh` (if `hive-env.sh` does not exist, create it in the Hive configuration directory).
Example:

```
export METASTORE_PORT=9083
```

5. Start the Hive Metastore service using one of the following commands:

If you want the Hive Metastore to be managed by Warden, the maprccli, and the Control System:

```
maprccli node services -name hivemeta -action start -nodes <space
delimited list of nodes>
```

If you want the Hive Metastore to be managed with standard hive commands:

```
/opt/mapr/hive/hive-<version>/bin/hive --service metastore --start
```

You can also use `nohup hive --service metastore` to run the Metastore in the background.

WARNING: If you have not configured a MySQL Metastore, do not run the Hive shell from an NFS mount location. If you try to do this, Hive will fail. The same problem will occur if you use the `hive-site.xml` file to configure the Metastore on an NFS mount location. Avoid both of these configurations.

Configuring a Remote MySQL Database for the Hive Metastore

About this task

After installing MySQL, perform the following steps to configure Hive Metastore on MySQL

Procedure

1. Install the MySQL connector. To install:

- **MySQL connector on a RHEL 6+ system**

On the Hive Metastore server host, install `mysql-connector-java` and symbolically link the file to the `/opt/mapr/hive/hive-<version>/lib/` directory.

```
$ sudo yum install
mysql-connector-java
$ ln -s /usr/share/
java/mysql-connector-java.jar /opt/
mapr/hive/hive-<version>/lib/
mysql-connector-java.jar
```

- **MySQL connector on a SLES system**

On the Hive Metastore server host, install `mysql-connector-java` and symbolically link the file to the `/opt/mapr/hive/hive-<version>/lib/` directory.

```
$ sudo zypper install
mysql-connector-java
$ ln -s /usr/share/
java/mysql-connector-java.jar /opt/
mapr/hive/hive-<version>/lib/
mysql-connector-java.jar
```

- **MySQL connector on a Debian/Ubuntu system**

On the Hive Metastore server host, install `mysql-connector-java` and symbolically

link the file into the /opt/mapr/hive/
hive-<version>/lib/ directory.

```
$ sudo apt-get install  
libmysql-java  
$ ln -s /usr/  
share/java/libmysql-java.jar /opt/  
mapr/hive/hive-<version>/lib/  
mysql-connector-java.jar
```

2. Create the database and an associated user. The following commands are for a Hive Metastore with hostname metastorehost to create a MySQL user with name hive and password mypassword:

```
$ mysql -u root -p  
  
mysql> CREATE DATABASE metastore;  
mysql> CREATE USER 'hive'@'metastorehost' IDENTIFIED BY 'mypassword';  
...  
mysql> REVOKE ALL PRIVILEGES, GRANT OPTION FROM 'hive'@'metastorehost';  
mysql> GRANT ALL PRIVILEGES ON metastore.* TO 'hive'@'metastorehost';  
mysql> FLUSH PRIVILEGES;  
mysql> quit;
```

- Configure the Metastore service to communicate with the MySQL database by setting the necessary properties (shown below) in the `/opt/mapr/hive/hive-<version>/conf/hive-site.xml` file. Suppose a MySQL database running on `myhost` and the user account `hive` with the password `mypassword`, set the following properties (overwriting any existing values) in the `hive-site.xml` file:

```
<property>
  <name>javax.jdo.option.ConnectionURL</name>
  <value>jdbc:mysql://myhost/metastore</value>
  <description>the URL of the MySQL database</description>
</property>

<property>
  <name>javax.jdo.option.ConnectionDriverName</name>
  <value>com.mysql.jdbc.Driver</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionUserName</name>
  <value>hive</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionPassword</name>
  <value>mypassword</value>
</property>

<property>
  <name>hive.metastore.uris</name>
  <value>thrift://<n.n.n.n>:9083</value>
  <description>IP address (or fully-qualified domain name) and port of
the metastore host</description>
</property>
```

NOTE: Though you can set the same `hive-site.xml` properties on all the hosts (client, Metastore, HiveServer), `hive.metastore.uris` is the only property that must be configured on all the hosts; the other properties are only needed on the Metastore host.

- Run `schemaTool` to create the initial DB structure.

```
/opt/mapr/hive/hive-<version>/bin/schematool -dbType mysql -initSchema
```

Configuring a Remote PostgreSQL Database for the Hive Metastore

Before you can run the Hive metastore with a remote PostgreSQL database, you must configure a JDBC driver to the remote PostgreSQL database, set up the initial database schema, and configure the PostgreSQL user account for the Hive user.

After installing PostgreSQL, perform the following steps to configure Hive Metastore on PostgreSQL.

Installing and Configuring PostgreSQL for the Hive Metastore

- Download the PostgreSQL JDBC driver.

Refer to the official [PostgreSQL JDBC Driver website](#) to download the JDBC driver and get information about the latest updates. Determine the appropriate database version and get the released drivers and JAR file.

- Run the following commands using `sudo`:

- a.** Move the JAR into the Java share directory:

```
sudo mv <postgresql-jdbc.jar> /usr/share/java/postgresql-jdbc.jar
```

- b.** Change the access mode of the JAR file to 644:

```
sudo chmod 644 /usr/share/java/postgresql-jdbc.jar
```

- c.** Create symbolic link to the /usr/lib/hive/lib/ directory, for example:

```
sudo ln -s /usr/share/java/postgresql-jdbc.jar /opt/mapr/hive/  
hive-<version>/lib/postgresql-jdbc.jar
```

- 3.** Create the Metastore database and user accounts:

```
$ sudo -u postgres psql  
  
postgres=# CREATE USER hiveuser WITH PASSWORD 'mypassword';  
postgres=# CREATE DATABASE metastore;
```

To verify the connection from the Metastore service host, run the following command:

```
psql -h myhost -U hiveuser -d metastore  
metastore=#
```

4. Configure the Metastore service to communicate with the PostgreSQL database by setting the necessary properties (shown below) in the `/opt/mapr/hive/hive-<version>/conf/hive-site.xml` file. Suppose a PostgreSQL database running on host `myhost` under the user account `hive` with the password `mypassword`, set the following configuration properties in the `hive-site.xml` file:

```
<property>
  <name>javax.jdo.option.ConnectionURL</name>
  <value>jdbc:postgresql://myhost/metastore</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionDriverName</name>
  <value>org.postgresql.Driver</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionUserName</name>
  <value>hiveuser</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionPassword</name>
  <value>mypassword</value>
</property>

<property>
  <name>hive.metastore.uris</name>
  <value>thrift://<n.n.n.n>:9083</value>
  <description>IP address (or fully-qualified domain name) and port of
the metastore host</description>
</property>
```

NOTE: Though you can use the same `hive-site.xml` properties on all the hosts (client, metastore, HiveServer), `hive.metastore.uris` is the only property that must be configured on all of the hosts; the other properties are only needed on the Metastore host.

5. Run `schemaTool` to create the initial DB structure:

```
/opt/mapr/hive/hive-<version>/bin/schematool -dbType postgres -initSchema
```

Configuring a Remote Oracle Database for the Hive Metastore

About this task

After installing Oracle, perform the following steps to configure Hive Metastore on Oracle.

Procedure

1. Install the Oracle JDBC Driver.
 - a) Download the Oracle JDBC Driver (`ojdbc6.jar`) from the Oracle [website](#).
 - b) Move the `ojdbc6.jar` file to `/opt/mapr/hive/hive-<version>/lib/` directory

2. Create the Metastore database and user account.

Connect to your Oracle database as administrator, create the user that will use the Hive Metastore, and create the Metastore schema. For example:

```
$ sqlplus "sys as sysdba"
SQL> create user hiveuser identified by mypassword;
SQL> grant connect to hiveuser;
SQL> grant all privileges to hiveuser;
SQL> CREATE DATABASE metastore
```

3. Configure the Metastore service to communicate with the Oracle database by setting the necessary properties (shown below) in the /opt/mapr/hive/hive-<version>/conf/hive-site.xml file.

Suppose an Oracle database running on myhost and the user account hiveuser with the password mypassword, set the following properties (overwriting any existing values) in the hive-site.xml file:

```
<property>
  <name>javax.jdo.option.ConnectionURL</name>
  <value>jdbc:oracle:thin:@//myhost/metastore</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionDriverName</name>
  <value>oracle.jdbc.OracleDriver</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionUserName</name>
  <value>hiveuser</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionPassword</name>
  <value>mypassword</value>
</property>

<property>
  <name>hive.metastore.uris</name>
  <value>thrift://<n.n.n.n>:9083</value>
  <description>IP address (or fully-qualified domain name) and port of
the metastore host</description>
</property>
```

NOTE: Though you can set the same hive-site.xml properties on all the hosts (client, Metastore, HiveServer), hive.metastore.uris is the only property that must be configured on all the hosts; the other properties are only needed on the Metastore host.

4. Run schemaTool to create the initial DB structure.

```
/opt/mapr/hive/hive-<version>/bin/schematool -dbType oracle -initSchema
```

Configuring an Oracle Schema

You must create schemas for Oracle databases manually.

About this task

Use schematool to view and create relational database management system (RDBMS) schemas.

See [Apache Hive documentation](#) for the detailed steps.

Configuring a Remote MS SQL SERVER Database for the Hive Metastore

About this task

After installing MS SQL, perform the following steps to configure Hive Metastore on MS SQL.

Procedure

1. Create hiveuser and Metastore schema.

```
1>CREATE DATABASE metastore;  
2>GO  
1>CREATE LOGIN <hiveuser> with password='<mypassword>;  
2>CREATE USER <hiveuser> for login <hiveuser>;  
3>GRANT <PRIVILEGES> to <hiveuser>;  
4>GO
```

2. Download JDBC Driver from [here](#), untar the file, and follow instructions in the `install.txt` file to install the driver.

3. Copy the JAR file to `/opt/mapr/hive/hive-version>/lib/` directory.

- For Java 7

```
cp ~/sqljdbc_6.0/enu/jre7/sqljdbc41.jar /opt/mapr/hive/  
hive-<version>/lib/
```

- For Java 8

```
cp ~/sqljdbc_6.0/enu/jre8/sqljdbc42.jar /opt/mapr/hive/  
hive-<version>/lib/
```

4. Configure the Metastore service to communicate with the MS SQL database by setting the necessary properties (shown below) in the `/opt/mapr/hive/hive-<version>/conf/hive-site.xml` file. Suppose an MS SQL database running on myhost and the user account hiveuser with the password mypassword, set the following properties (overwriting any existing values) in the `hive-site.xml` file:

```
<property>
  <name>javax.jdo.option.ConnectionURL</name>
  <value>jdbc:sqlserver://<SERVER_NAME>:1433;DatabaseName=metastore;</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionDriverName</name>
  <value>com.microsoft.sqlserver.jdbc.SQLServerDriver</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionUserName</name>
  <value>hiveuser</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionPassword</name>
  <value>mypassword</value>
</property>

<property>
  <name>hive.metastore.uris</name>
  <value>thrift://<n.n.n.n>:9083</value>
  <description>IP address (or fully-qualified domain name) and port of
the metastore host</description>
</property>
```

NOTE: Though you can set the same `hive-site.xml` properties on all the hosts (client, Metastore, HiveServer), `hive.metastore.uris` is the only property that must be configured on all the hosts; the other properties are only needed on the Metastore host.

5. Run `schemaTool` to create the initial DB structure.

```
/opt/mapr/hive/hive-<version>/bin/schematool -dbType mssql -initSchema
```

Configuring MariaDB for the Hive Metastore

Installing MariaDB

To install MariaDB, use the MariaDB Repository Configuration Tool. See [MariaDB Downloads](#).

Configuring Repositories

The following steps describe how to configure a repository and install the latest available stable version of MariaDB for different operating systems.

1. Configure a repository for MariaDB:

- **Red Hat / CentOS and SLES**

Copy and paste the following custom MariaDB repository entry into a file under `/etc/yum.repos.d/`. You can name the file `MariaDB.repo` or something similar:

```
# MariaDB <version> RedHat repository list
# http://downloads.mariadb.org/mariadb/repositories/
[mariadb]
name = MariaDB
baseurl = http://yum.mariadb.org/<version>/rhel7-amd64
gpgkey=https://yum.mariadb.org/RPM-GPG-KEY-MariaDB
gpgcheck=1
```

- **Ubuntu**

You can also create a custom MariaDB `sources.list` file. To do so, after importing the signing key as outlined above, copy and paste the following into a file under `/etc/apt/sources.list.d/`. You can name the file `MariaDB.list` or something similar. Or you can add it to the bottom of your `/etc/apt/sources.list` file:

```
# MariaDB <version> repository list - created 2020-04-17 08:34 UTC
# http://downloads.mariadb.org/mariadb/repositories/
deb [arch=amd64,arm64,ppc64el] http://mirror.mephi.ru/mariadb/repo/
<version>/ubuntu bionic main
deb-src http://mirror.mephi.ru/mariadb/repo/<version>/ubuntu bionic
main
```

2. After the `sources.list` file is in place, install MariaDB:

- **Red Hat / CentOS**

```
sudo yum clean all && sudo yum install mariadb-server mariadb-client
```

- **SLES**

```
sudo zypper update && sudo zypper install mariadb
```

- **Ubuntu**

```
sudo apt update && sudo apt install mariadb-server
```

3. Start the MariaDB server:

- **Red Hat / CentOS and Ubuntu**

```
sudo service mariadb start
```

- **SLES**

```
sudo systemctl start mariadb
```

4. In the command line, run the `mysql_secure_installation` shell script:

```
sudo mysql_secure_installation
Enter current password for root (enter for none): press Enter
Set root password? Y
New password: Type new root password
Re-enter new password: Confirm the password
Remove anonymous users? Y
Disallow root login remotely? Y
Remove test database and access to it? Y
Reload privilege tables now? Y
```

Configuring a JDBC Driver for MariaDB

Before you can run the Hive Metastore with a MariaDB database, you must:

- Configure a JDBC driver for the MariaDB database.
- Set up the initial database schema.
- Configure the MariaDB user account for the Hive user.

Use the following steps:

1. Install the MariaDB Connector/J manually with a `.jar` file. The MariaDB Connector/J can also be installed by manually installing a `.jar` file to a directory in your CLASSPATH. Download the MariaDB Connector/J `.jar` files from the following URL: <https://downloads.mariadb.com/Connectors/java/connector-java-2.5.4/>.
2. Copy the `.jar` files to the `/opt/mapr/hive/hive-<version>/lib/` directory:

```
cp mariadb-java-client-2.5.4-sources.jar /opt/mapr/hive/
hive-<version>/lib/
cp mariadb-java-client-2.5.4.jar /opt/mapr/hive/hive-<version>/lib/
cp mariadb-java-client-2.5.4-javadoc.jar /opt/mapr/hive/
hive-<version>/lib/
```

3. Restart Hive services:

```
maprcli node services -name hivemeta -action restart -nodes
<HMS_node_list>
maprcli node services -name hs2 -action restart -nodes <HS2_node_list>
```

4. Create the Hive Metastore database and user accounts:

```
$ mysql -u root -p <password>

MariaDB [(none)]> CREATE USER hiveuser IDENTIFIED BY PASSWORD 'password';
MariaDB [(none)]> CREATE DATABASE metastore;
MariaDB [(none)]> REVOKE ALL PRIVILEGES, GRANT OPTION FROM
'hiveuser'@'metastorehost';
MariaDB [(none)]> GRANT ALL PRIVILEGES ON metastore.* TO
'hiveuser'@'metastorehost';
MariaDB [(none)]> FLUSH PRIVILEGES;
MariaDB [(none)]> quit;
```

Configuring the Hive Metastore on MariaDB

Use these steps:

1. In the Hive configuration directory (/opt/mapr/hive/hive-<version>/conf), update the hive-site.xml file with the following properties. Beginning with EEP 7.0.0, you must use the MySQL driver with MariaDB:

```
<property>
  <description>the URL of the MariaDB database</description>
  <name>javax.jdo.option.ConnectionURL</name>
  <value>jdbc:mysql://<hostname>:3306/metastore</value>
</property>
<property>
  <name>javax.jdo.option.ConnectionDriverName</name>
  <value>com.mysql.jdbc.Driver</value>
</property>
<property>
  <name>javax.jdo.option.ConnectionUserName</name>
  <value>hiveuser</value>
</property>
<property>
  <name>javax.jdo.option.ConnectionPassword</name>
  <value><fill in with password></value>
</property>
<property>
  <description>IP address (or FQDN) and port of the metastore host</
description>
  <name>hive.metastore.uris</name>
  <value>thrift://<hostname>:9083</value>
</property>
```

2. Run the schematool command as an initialization step:

```
/opt/mapr/hive/hive-<version>/bin/schematool -dbType mysql -initSchema
```

Considerations for MariaDB 11.0.1 or later versions

A change introduced in MariaDB 11.0.1 modifies the server's internal identifier from MySQL to MariaDB. For more information, see <https://jira.mariadb.org/browse/MDEV-29582>. To update Data Fabric as per server's internal identifier changes, do the following configuration changes:

In hive-site.xml:

1. Use jdbc:mariadb in javax.jdo.option.ConnectionURL property.
2. Add sessionVariables=sql_mode=ANSI_QUOTES.
3. Add useMySQLMetadata=true:

```
<property>
  <name>javax.jdo.option.ConnectionURL</name>
  <value>jdbc:mariadb://<HOSTNAME>:3306/hive?
createDatabaseIfNotExist=true&sessionVariables=sql_mode=ANSI_QUOTES&a
mp;useMySQLMetadata=true</value>
</property>
```

4. Use `org.mariadb.jdbc.Driver` in `javax.jdo.option.ConnectionDriverName` property:

```
<property>
  <name>javax.jdo.option.ConnectionDriverName</name>
  <value>org.mariadb.jdbc.Driver</value>
</property>
```

5. Download and add **mariadb-java-client-3.5.6.jar** from [Connector/J – All releases](#) to `/opt/mapr/hive/hive-3.1.3/lib/` folder.
6. Add `ANSI_QUOTES` to MariaDB's global variable `sql_mode`.
7. Edit `/etc/my.cnf` as follows:

```
[mysqld]
# keep your existing modes, just add ANSI_QUOTES
sql_mode=STRICT_TRANS_TABLES,NO_ENGINE_SUBSTITUTION,ANSI_QUOTES
```

8. Restart the MariaDB server:

```
sudo systemctl restart mariadb
```

9. Restart Hive services:

```
maprcli node services -name hivemeta -action restart -nodes
<HMS_node_list>
maprcli node services -name hs2 -action restart -nodes <HS2_node_list>
```

User Impersonation for Hive

User impersonation enables Hive to submit jobs as a particular user. Without impersonation, Hive submits queries and hadoop commands as the user that started HiveServer2 and Hive Metastore. On a Data Fabric cluster, this user is typically the `mapr` user or the user specified in the `MAPR_USER` [environment variable](#).

NOTE: Impersonation is enabled by default.

Enable User Impersonation

On non-secure clusters

Procedure

1. Set the following properties in the `/opt/mapr/hive/<version>/conf/hive-site.xml` file on the nodes where HiveServer2 is installed:

```
<property>
  <name>hive.server2.enable.doAs</name>
  <value>true</value>
  <description>Set this property to enable impersonation in Hive Server
2</description>
</property>
<property>
  <name>hive.metastore.execute.setugi</name>
  <value>true</value>
  <description>Set this property to enable Hive Metastore service
impersonation in non-secure mode. In non-secure mode, setting this
property to true will cause the metastore to execute DFS operations
using the client's reported user and group permissions. Note that this
property must be set on both the client and server sides. If the client
sets it to true and the server sets it to false, the client setting will
be ignored.</description>
</property>
```

2. Set the following property `/opt/mapr/hive/<version>/conf/hive-site.xml` file on the nodes where Hive Metastore is installed:

```
<property>
  <name>hive.metastore.execute.setugi</name>
  <value>true</value>
  <description>Set this property to enable Hive Metastore service
impersonation in non-secure mode. In non-secure mode, setting this
property to true will cause the metastore to execute DFS operations
using the client's reported user and group permissions. Note that this
property must be set on both the client and server sides. If the client
sets it to true and the server sets it to false, the client setting will
be ignored.</description>
</property>
```

On secure (MAPR-SASL and Kerberos) clusters

Procedure

1. Set the following properties in the `/opt/mapr/hive/<version>/conf/hive-site.xml` file on the nodes where HiveServer2 is installed:

```
<property>
  <name>hive.server2.enable.doAs</name>
  <value>true</value>
  <description>Set this property to enable impersonation in Hive Server
2</description>
</property>
<property>
  <name>hive.metastore.execute.setugi</name>
  <value>false</value>
  <description>Set this property to enable Hive Metastore service
impersonation in non-secure mode. In non-secure mode, setting this
property to true will cause the metastore to execute DFS operations
using the client's reported user and group permissions. Note that this
property must be set on both the client and server sides. If the client
sets it to true and the server sets it to false, the client setting will
be ignored.</description>
</property>
```

2. Set the following property `/opt/mapr/hive/<version>/conf/hive-site.xml` file on the nodes where Hive Metastore is installed:

```
<property>
  <name>hive.metastore.execute.setugi</name>
  <value>false</value>
  <description>Set this property to enable Hive Metastore service
impersonation in non-secure mode. In non-secure mode, setting this
property to true will cause the metastore to execute DFS operations
using the client's reported user and group permissions. Note that this
property must be set on both the client and server sides. If the client
sets it to true and the server sets it to false, the client setting will
be ignored.</description>
</property>
```

NOTE: The `hive.metastore.execute.setugi` property is set to false automatically after `/opt/mapr/server/configure.sh -R` is running.

On both secure and non-secure clusters

Procedure

On nodes where the **Resource Manager** and the **Node Manager** are installed, set the following properties in the `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/core-site.xml` file:

```
<property>
  <name>hadoop.proxyuser.mapr.groups</name>
  <value>*</value>
  <description>Allow the superuser mapr to impersonate any member of any
group</description>
</property>
<property>
  <name>hadoop.proxyuser.mapr.hosts</name>
  <value>*</value>
  <description>The superuser can connect from any host to impersonate a
```

```
user</description>
</property>
```

Results

WARNING: The impersonated user must have write permissions to /user/hive/warehouse and /user/mapr-user/tmp/hive directories.

Verify that User Impersonation is Enabled

About this task

To verify that Hive queries do not run as the mapr user, connect to HiveServer2 as a user other than mapr. Then run queries and verify that queries were run as the user that connected to HiveServer2.

To verify that hadoop commands submitted by Hive do not run as the mapr user, start the shell or connect to HiveServer2 as a user other than mapr. Then create some tables, and verify that the tables in /user/hive/warehouse are created under the user that started the shell or the user connected to HiveServer2.

Example: Hive Impersonation

The following examples illustrate Hive impersonation:

Example 1

1. Log in as a non-mapr user and generate a Data Fabric ticket:

```
$ su mapruser1
$ maprlogin password
```

2. Connect to HiveServer2:

```
$ hive --service beeline
Beeline version 2.3.3-mapr-SNAPSHOT by Apache Hive
beeline> !connect jdbc:hive2://node4.cluster.com:10000/
default;ssl=true;auth=maprsasl
Connecting to jdbc:hive2://node4.cluster.com:10000/
default;ssl=true;auth=maprsasl
Connected to: Apache Hive (version 2.3.3-mapr-SNAPSHOT)
Driver: Hive JDBC (version 2.3.3-mapr-SNAPSHOT)
Transaction isolation: TRANSACTION_REPEATABLE_READ
```

3. Create a table, and upload data:

```
0: jdbc:hive2://node4.cluster.com:10000/defau> create table
impersonation_example_first (id int, username string);
0: jdbc:hive2://node4.cluster.com:10000/defau> insert into
impersonation_example_first values (1, 'mapruser1');
```

4. To check that impersonation works, use the following commands to check the /warehouse directory of the Data Fabric file system:

```
$ hadoop fs -ls /user/hive/warehouse
Found 1 items
drwxr-xr-x - mapruser1 mapruser1 1 2019-05-22 14:40
/user/hive/warehouse/impersonation_example_first

$ hadoop fs -ls /user/hive/warehouse/impersonation_example_first
Found 1 items
-rwxrwxrwx 3 mapruser1 mapruser1 12 2019-10-15 07:21
/user/hive/warehouse/impersonation_example_first/000000_0
```

Example 2

1. Generate a Data Fabric ticket for a non-mapr user.
2. Connect through JDBC using the `hive.server2.proxy.user` option with a non-mapr user name as an argument:

```
$ hive --service beeline
beeline> !connect
jdbc:hive2://node4.cluster.com:10000/
default;auth=maprsasl;ssl=true;hive.server2.proxy.user=mapruser1
Connecting to
jdbc:hive2://node4.cluster.com:10000/
default;auth=maprsasl;ssl=true;hive.server2.proxy.user=mapruser1
Client: auth-conf,auth-int,auth.Using Server one
Connected to: Apache Hive (version 2.3.3-mapr-SNAPSHOT)
Driver: Hive JDBC (version 2.3.3-mapr-SNAPSHOT)
Transaction isolation: TRANSACTION_REPEATABLE_READ
```

3. Create a table and upload data:

```
0: jdbc:hive2://node4.cluster.com:10000/default> create table
impersonation_example_second (id int);
0: jdbc:hive2://node4.cluster.com:10000/default> insert into table
impersonation_example_second values (1), (2), (3), (5);
```

4. Check the owner of the table and data:

```
$ hadoop fs -ls /user/hive/warehouse/impersonation_example_second
Found 1 items
drwxrwxrwx - mapruser1 mapruser1 1 2019-05-23 12:29
/user/hive/warehouse/impersonation_example_second

$ hadoop fs -ls /user/hive/warehouse/impersonation_example_second
Found 1 items

```

Hive Security

You can configure the following features for Hive security:

Hive Security Configuration Options

This section describes changes made in Hive default configuration. It shows how to configure Hive after manual installation.

Unlike the previous releases, starting in EEP 4.0, Hive should be configured by running the `$MAPR_HOME/server/configure.sh` script with the `-R` option after installing Hive. Hive demons will not start automatically if Hive is not configured correctly. The security configuration are described in the following sections:

1. Automatic
2. Manual
3. Custom

NOTE: Do not use ecosystem `$HIVE_HOME/bin/configure.sh` script for Hive configuration. Every configuration of Hive should be done via the `$MAPR_HOME/server/configure.sh` utility by running it with the `-R` option. The core `$MAPR_HOME/server/configure.sh` utility invokes the ecosystem `configure.sh` script automatically with appropriate security option.

Automatic

If you installed Hive using the Data Fabric Installer, the Data Fabric Installer configures Hive daemons during installation. Additional configuration is not required.

Manual

After a new manual installation, to generate a valid default ecosystem configuration, run:

```
$MAPR_HOME/server/configure.sh -R
```

Table

Node, Package	Hive	HiveServer2	Hive Metastore	WebHCat
Node 1	X	X		
Node 2	X		X	
Node 3	X			X

- After a manual installation, run the following command on Node 1, Node 2, and Node 3:

```
$MAPR_HOME/server/configure.sh -R
```

As a result:

- All Hive daemons are configured to support MapR-SASL. If the `hive.metastore.sasl.enabled` property is enabled in the `hive-site.xml` file, its value is set to `true`. If the property is not present, it is added in the configuration section as follows:

```
<property>
  <name>hive.metastore.sasl.enabled</name>
  <value>true</value>
</property>
```

- HiveServer2 is configured to support encryption between Hiveserver2 and Hive clients. If the `hive.server2.thrift.sasl.qop` property is available in the `hive-site.xml` file, its value is set to `auth-conf`. If the property is not present, it is added in the configuration section as follows:

```
<property>
  <name>hive.server2.thrift.sasl.qop</name>
  <value>auth-conf</value>
</property>
```

- The `configure.sh` script creates a backup folder for the current Hive configuration before it changes the configuration. All configuration properties including `*.conf`, `*.properties`, and `*.xml` are saved in the backup folder.

```
$HIVE_HOME/conf.YYYYMMDD_HHMMSS
```

- 644 Unix permissions are applied to all configuration files. Each run of `configure.sh` with the `-R` option overwrites permissions of the configuration files to 644.
- The Hive default ports listed below are verified as available. If a port is not available, the `configure.sh` script generates an error message during configuration.

Hive default ports are as follows:

Role	Default Port
Hive Metastore	9083
HiveServer2	10000
HiveWebHCat	50111

Custom

For PAM, LDAP, and Kerberos custom configurations, run `configure.sh` with the `-R` option:

```
$MAPR_HOME/server/configure.sh -R
```

The `hive-site.xml` file is not changed. However, Warden files are copied and a `HIVE_HOME/conf` backup folder is created.

Preventing a Non-Administrative User from Installing Hooks

For a fresh install of EEP 6.1, a non-administrative user is prevented from installing hooks by default. For a minor version update (for example, EEP 6.0.0 to EEP 6.1.0 or EEP 5.0.1 to EEP 5.0.2), you need to modify the Hive configuration to prevent a malicious user from using Hive hooks to install malware on your Data Fabric cluster.

About this task

In general, a hook is a mechanism for intercepting events, messages, or function calls during processing. Hive hooks are a mechanism to tie into the internal workings of Hive without the need of re-compiling Hive. Hive hooks, in this sense, provide the ability to extend and integrate external functionality with Hive.

Any user using beeline can install Java code as a Hive hook. On HPE Data Fabric, these hooks run as the `mapr` user, which could represent a security vulnerability. To prevent a malicious user from using Hive hooks to install malware on a Data Fabric cluster, the cluster admin should add the following properties to the default value of `hive.conf.restricted.list` in the `hive-site.xml` file, and then restart HiveServer 2 (HS2):

- `hive.exec.pre.hooks`

- `hive.exec.post.hooks`
- `hive.exec.failure.hooks`
- `hive.exec.query.redactor.hooks`

Adding the properties prevents a non-admin user from installing hooks into Hive.

Procedure

1. Add all hook-related properties to the default value of `hive.conf.restricted.list` in the `hive-site.xml` file:

Hive 2.3

- `hive.exec.pre.hooks`
- `hive.exec.post.hooks`
- `hive.exec.failure.hooks`
- `hive.exec.query.redactor.hooks`
- `hive.semantic.analyzer.hook`
- `hive.query.lifetime.hooks`
- `hive.exec.driver.run.hooks`
- `hive.server2.session.hook`

Hive 2.1

- `hive.exec.pre.hooks`
- `hive.exec.post.hooks`
- `hive.exec.failure.hooks`
- `hive.exec.query.redactor.hooks`
- `hive.semantic.analyzer.hook`
- `hive.exec.driver.run.hooks`
- `hive.server2.session.hook`

2. Make sure `hive.conf.restricted.list` configuration parameter already has a default value which contains:

Hive 2.3

```
hive.security.authenticator.manager
hive.security.authorization.manager
Hive.security.metastore.authorization.manager
hive.security.metastore.authenticator.manager
Hive.users.in.admin.role,hive.server2.xsrf.filter.enabled
hive.security.authorization.enabled
hive.server2.authentication.ldap.basedn
hive.server2.authentication.ldap.url
hive.server2.authentication.ldap.Domain
```

```
hive.server2.authentication.ldap.groupDNPattern
hive.server2.authentication.ldap.groupFilter
hive.server2.authentication.ldap.useDNPattern
hive.server2.authentication.ldap.useFilter
hive.server2.authentication.ldap.groupMembershipKey
hive.server2.authentication.ldap.useMembershipKey
hive.server2.authentication.ldap.groupClassKey
hive.server2.authentication.ldap.customLDAPQuery
```

Hive 2.1

```
hive.security.authenticator.manager
hive.security.authorization.manager
hive.users.in.admin.role
hive.server2.xsrf.filter.enabled
```

3. Add the default values already present in `hive.conf.restricted.list` to the `hive-site.xml` file:

Hive 2.3

```
<property>
  <name>hive.conf.restricted.list</name>
  <value>

hive.security.authenticator.manager,
hive.security.authorization.manager,
hive.security.metastore.authorization.manager,
hive.security.metastore.authenticator.manager,
hive.users.in.admin.role,hive.server2.xsrf.filter.enabled,
hive.security.authorization.enabled,
hive.server2.authentication.ldap.basedn,
hive.server2.authentication.ldap.url,
hive.server2.authentication.ldap.Domain,
hive.server2.authentication.ldap.groupDNPattern,
hive.server2.authentication.ldap.groupFilter,
```

```

upFilter,

hive.server2.authentication.ldap.use
rDNPattern,

hive.server2.authentication.ldap.use
rFilter,

hive.server2.authentication.ldap.gro
upMembershipKey,

hive.server2.authentication.ldap.use
rMembershipKey,

hive.server2.authentication.ldap.gro
upClassKey,

hive.server2.authentication.ldap.cus
tomLDAPQuery,
    hive.exec.pre.hooks,
    hive.exec.post.hooks,
    hive.exec.failure.hooks,
    hive.exec.query.redactor.hooks,
    hive.semantic.analyzer.hook,
    hive.query.lifetime.hooks,
    hive.exec.driver.run.hooks,
    hive.server2.session.hook,
</value>
</property>

```

Hive 2.1

```

<property>
  <name>hive.conf.restricted.list</
name>
  <value>

hive.security.authenticator.manager,

hive.security.authorization.manager,
    hive.users.in.admin.role,

hive.server2.xsrf.filter.enabled,
    hive.exec.pre.hooks,
    hive.exec.post.hooks,
    hive.exec.failure.hooks,
    hive.exec.query.redactor.hooks,
    hive.semantic.analyzer.hook,
    hive.exec.driver.run.hooks,
    hive.server2.session.hook,
  </value>
</property>

```

NOTE: Values of the `hive.conf.restricted.list` are split into separate lines for better readability. In the actual `hive-site.xml` file, no spaces or newlines exist between the commas.

Configuring Security Headers for Web Servers

This section describes how to configure response headers for REST API servers used in Hive WebHCat and the HiveServer2 web UI.

About the Headers File

The XML file with security headers is located at:

```
/opt/mapr/hive/hive-<version>/conf/headres.xml
```

The headres.xml file contains the following headers:

```
<?xml version="1.0" encoding="utf-8" ?>
<!DOCTYPE properties SYSTEM "http://java.sun.com/dtd/properties.dtd">
<properties>
  <entry key="X-Content-Type-Options">nosniff</entry>
  <entry key="X-XSS-Protection">1; mode=block</entry>
  <entry key="Strict-Transport-Security">max-age=31536000;
includeSubDomains</entry>
  <entry key="Content-Security-Policy">default-src https:</entry>
</properties>
```

This table describes each header:

Header	Description	Default Value
X-XSS-Protection	Stops pages from loading when reflected cross-site scripting (XSS) is detected. Supported by IE, Chrome, and Safari.	1: mode=block
X-Content-Type-Options	Indicates that the MIME types advertised in the Content-Type headers should not be changed and should be followed.	nosniff
Strict-Transport-Security	Tells all browsers that the website should only be accessed using HTTPS instead of using HTTP.	max-age=31536000;includeSubDomains
Content-Security-Policy	Allows web-site administrators to control resources the user agent is allowed to load for a given page. This helps guard against cross-site scripting attacks (XSS).	default-src https:

Configuring Security Headers for WebHCat

To enable security headers for WebHCat, add the following to the webhcat-site.xml file, and replace <version> with your Hive version:

```
<property>
<name>templeton.jetty.response.headers.file</name>
<value>/opt/mapr/hive/hive-<version>/conf/headers.xml</value>
</property>
```

After configuring and restarting WebHCat, you should see security headers in the server response. For example:

```
< HTTP/1.1 200 OK
< Date: Thu, 03 Oct 2019 11:35:39 GMT
< Set-Cookie:
hadoop.auth="u=mapr&p=mapr&t=multiauth&e=1570138539451&s=CpX+tI7sScnnSUZpA1K
df+7hamM="; Path=/; Domain=.cluster.com; Expires=Thu, 03-Oct-2019 21:35:39
GMT; Secure; HttpOnly
< Content-Security-Policy: default-src https:
< X-XSS-Protection: 1; mode=block
< X-Content-Type-Options: nosniff
< Strict-Transport-Security: max-age=31536000
< Content-Type: application/json
```

```
< Transfer-Encoding: chunked
< Server: Jetty(9.4.19.v20190610)
```

Configuring Security Headers for HiveServer2 Web UI

To enable security headers for the Hiveserver2 Web UI, add the following to the `hive-site.xml` file, replacing `<version>` with your Hive version:

```
<property>
  <name>hive.server2.webui.jetty.response.headers.file</name>
  <value>/opt/mapr/hive/hive-<version>/conf/headers.xml</value>
</property>
```

Then restart HiveServer2.

Configuring Custom Headers

To configure custom headers for web servers, edit the `headers.xml` file, and add Custom-header as follows:

```
<entry key="Custom-header">custom-value</entry>
```

Security Headers Auto-Configuration

If you install Hive on a secure cluster (MapR SASL or Kerberos) and run the following command after Hive installation, Hive automatically configures itself to enable security headers, and no additional action is needed:

```
/opt/mapr/server/configure.sh -R
```

Hive Authentication

The authentication method that you configure for the Hive Metastore, HiveServer2, and WebHcat determines how these Hive components access and connect to each other.

Clients of these components may require additional configuration and specific connection strings based on the selected authentication method.

To enable and use authentication for Hive, complete the following steps:

1. Determine which authentication methods are supported for each component and its clients.
2. Configure authentication for Hive components and their clients. See the following topics:
 - [Authentication for Hive Metastore](#)
 - [Authentication for HiveServer2](#)
 - [Authentication for WebHCat](#)
3. Determine how clients connect to each component. See [Connecting to Hive](#).

Hive Metastore Authentication Support

The following table describes the different supported authentication methods for Hive Metastore and how it impacts the authentication options for its clients:

Data Fabric Cluster	Hive Metastore (Remote) Authentication	HiveServer 2 Authentication Options	WebHCat Authentication Options
Secure	NONE	<ul style="list-style-type: none"> NONE KERBEROS LDAP PAM CUSTOM MAPRSASL NOSASL 	PAM
Secure	KERBEROS	KERBEROS	KERBEROS with SPNEGO
Secure	MAPRSASL (default)*	MAPRSASL (default)*	PAM
Not Secure	NONE	NONE	Simple authentication with <user.name> only
*As of Hive 0.13-1504 and Hive 1.0-1504, Hive Metastore supports MapR-SASL and MapR-SASL is enabled by default when the Data Fabric cluster is secure.			

HiveServer2 Authentication Support

The following table describes the different supported authentication option for HiveServer2 based on the authentication method configured for Hive Metastore:

Data Fabric Cluster	Hive Metastore (Remote) Authentication	HiveServer 2 Authentication Options
Secure	NONE	NONE
Secure	NONE	KERBEROS
Secure	NONE	LDAP
Secure	NONE	PAM (default)*
Secure	NONE	CUSTOM
Secure	NONE	MAPRSASL*
Secure	KERBEROS	KERBEROS
Secure	MAPRSASL (default)*	MAPRSASL*
Not Secure	NONE	NONE
*As of Hive 0.13-1510, Hive 1.0-1510, and Hive 1.2.1-1510, PAM and MapR-SASL are enabled by default when the cluster is secure. In Hive 0.13-1508 and Hive 1.0-1508, PAM is enabled by default when the cluster is secure. In Hive 0.13-1504 and Hive 1.0-1504, MapR-SASL is supported and enabled by default when the Data Fabric cluster is secure.		

Clients of HiveServer2 authenticate with the same authentication method that is configured for HiveServer2. Clients of HiveServer 2 include ODBC, JDBC, and Beeline.

NOTE: Connections to HiveServer2 using ODBC do not support MapR-SASL.

WebHCat Authentication Support

The following table describes the different authentication options for WebHCat based on the authentication method configured for Hive Metastore :

Data Fabric Cluster	Hive Metastore (Remote) Authentication	WebHCat Authentication
Secure	KERBEROS	KERBEROS with SPNEGO
Secure	KERBEROS	PAM
Secure	MAPRSASL (default)*	PAM
Not Secure	NONE	Simple authentication with user.name only
*As of Hive 0.13-1504 and Hive 1.0-1504, Hive Metastore supports MapR-SASL and MapR-SASL is enabled by default when the Data Fabric cluster is secure.		

Clients of WebHCat authenticate with the same authentication method that is configured for WebHCat. Web browsers are clients of WebHCat.

Description of Security Values

The following table describes the different security values:

Authentication Options	Description
NONE	No authentication check
LDAP	LDAP/AD based authentication
KERBEROS	Kerberos/GSSAPI authentication
CUSTOM	Custom authentication provider (use with property <code>hive.server2.custom.authentication.class</code>)
PAM	Pluggable authentication module
NOSASL	Raw transport
MAPRSASL	MapR SASL security

Authentication for Hive Metastore

You can configure authentication for in-bound client connections to the Hive Metastore when the metastore is remote, not embedded. Clients of Hive Metastore include the HiveCLI, HCatalog, HiveServer2, and WebHCat.

Hive Metastore supports the following authentication methods:

- MapR-SASL authentication
- Kerberos Authentication

MapR-SASL Authentication

MapR-SASL is available starting with the 1504 release of Hive 0.13 and Hive 1.0 and it is the default authentication method when the cluster is secure.

Kerberos Authentication

When the cluster is secure, you can configure Hive Metastore to use Kerberos authentication. You must also configure Hive Metastore clients to use Kerberos when authenticating with Hive Metastore.

Configuring Hive Metastore Authentication

This section describes how to configure the `hive.metastore.authentication` property for secured and unsecured clusters. It describes cases when the property must be configured explicitly and when it can be omitted from `hive-site.xml`.

Hive Metastore supports two types of authentication: MAPRSASL and KERBEROS. At startup, Hive Metastore reads the system property `metastore.auth`. If `metastore.auth` is equal to null, then the authentication type is NONE. Otherwise, Hive Metastore takes the value of the system property `metastore.auth` and assigns it to the Hive Metastore configuration property `hive.metastore.authentication`.

You do not need to set up the `metastore.auth` system property manually. If a cluster is secured, Hive assigns the MAPRSASL value to the `metastore.auth` property. If a cluster is not secured, Hive assigns the NONE value to the `metastore.auth` property.

To enable Kerberos authentication, set the value of `hive.metastore.authentication` directly in `hive-site.xml`, as shown in the following table:

Table

Security	Value of <code>hive.metastore.authentication</code>	Notes
No security	NONE	The value is set automatically. You do not need to make an entry in <code>hive-site.xml</code> .
MapR SASL security	MAPRSASL	The value is set automatically. You do not need to make an entry in <code>hive-site.xml</code> .
Kerberos security	KERBEROS	You must make the following entry in <code>hive-site.xml</code> : <pre><property> <name>hive.metastore.authentication</name> <value>KERBEROS</value> </property></pre>

Configure Hive Metastore to use MapR-SASL

About this task

Procedure

Edit the `/opt/mapr/conf/env.sh` file and set the following properties:

```
MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=maprsasl"
MAPR_HIVE_SERVER_LOGIN_OPTS="-Dhadoop.login=maprsasl_keytab"
```

Configuring Hive Metastore Clients to use MapR-SASL

About this task

The Hive metastore clients are configured to use MapR-SASL when authenticating with Hive Metastore.

NOTE: Hive Metastore clients must provide a valid Data Fabric ticket to connect to the Hive Metastore. See [Connecting to Hive](#) on page 5056 for details.

Procedure

1. Ensure that the cluster is secure.
2. Edit the `/opt/mapr/conf/env.sh` file and set the following property:

```
MAPR_HIVE_LOGIN_OPTS="-D hadoop.login=maprsasl"
```

Configure Hive Metastore to use Kerberos

About this task

Enabling Hive Metastore to use Kerberos authentication requires a kerberos principal, kerberos keytab, and the following configurations.

Complete the following steps on each node where a Hive Metastore is installed:

Procedure

1. Create a Kerberos server identity and add it to a keytab file. You can use the following commands in a Linux-based Kerberos environment to set up the identity and update the keytab file:

NOTE: MapR clusters do not provide Kerberos infrastructure. The tips in this step assume a Linux-based Kerberos environment, and the specific commands for your environment may vary. Consult with your Kerberos administrator for assistance.

```
# kadmin
: addprinc -randkey username/<FQDN@REALM>
: ktadd -k /opt/mapr/conf/hive.keytab username/<FQDN@REALM>
```

The `hive.keytab` file must be owned and readable only by the `mapr` user.

2. Configure the following properties in the following file:

```
/opt/mapr/hive/hive-<version>/conf/hive-site.xml
```

Property	Value
<code>hive.metastore.kerberos.keytab.file</code>	The Keytab file that contains the HiveMetastore principal.
<code>hive.metastore.kerberos.principal</code>	<The HiveMetastore principal. For example, <code>mapr/<FQDN@REALM>.></code>

```
<property>
  <name>hive.metastore.kerberos.keytab.file</name>
  <value>/opt/mapr/conf/metastore.keytab</value>
  <description>The path to the Kerberos Keytab file
  containing the metastore thrift server's service principal.</
description>
</property>
<property>
  <name>hive.metastore.kerberos.principal</name>
  <value>mapr/<FQDN@REALM></value>
```

```
<description>The service principal for the metastore thrift server.
The special string _HOST will be replaced automatically with the correct
hostname.</description>
</property>
```

3. Configure the following properties in `/opt/mapr/conf/env.sh` on each node where the Hive Metastore is installed:

- Set `MAPR_HIVE_LOGIN_OPTS` to

```
"-Dhadoop.login=hybrid"
```

- Set `MAPR_HIVE_SERVER_LOGIN_OPTS` to

```
"-Dhadoop.login=hybrid"
```

Configure Hive Metastore Clients to use Kerberos

When the Hive Metastore is configured to use Kerberos authentication, you must also configure Hive Metastore Clients to use Kerberos when authenticating with Hive Metastore.

About this task

Complete the following steps on each node where a Hive Metastore client is installed:

Procedure

1. Configure `MAPR_HIVE_LOGIN_OPTS` to `"-Dhadoop.login=hybrid"` in `/opt/mapr/conf/env.sh`.
2. Configure the following property in `hive-site.xml`:

Property	Value
<code>hive.metastore.kerberos.principal</code>	The HiveMetastore principal. For example, <code>mapr/<FQDN@REALM></code> .

```
<property>
  <name>hive.metastore.kerberos.principal</name>
  <value>mapr/<FQDN@REALM></value>
  <description>The service principal for the metastore thrift server.
The special string _HOST will be replaced automatically with the correct
hostname.</description>
</property>
```

What to do next

See [Connecting to Hive](#) on page 5056 for details on how to connect to HiveMetastore once the server and client node are configured to use Kerberos.

NOTE: The `MAPR_HIVE_LOGIN_OPTS` and `MAPR_HIVE_SERVER_LOGIN_OPTS` were added in 1504 release of Hive 0.13 and Hive 1.0. If you have Hive 0.13 from a prior release, you do not need to configure these properties. Instead, set `MAPR_ECOSYSTEM_LOGIN_OPTS` and `MAPR_ECOSYSTEM_SERVER_LOGIN_OPTS` to `"-Dhadoop.login=hybrid"` in `/opt/mapr/conf/env.sh`.

Authentication for HiveServer2

You can configure authentication for in-bound client connection to HiveServer2. Clients of HiveServer 2 include beeline and odbc/jdbc client applications.

Credentials are submitted from the HiveServer2 clients to HiveServer2 as plain text. To secure the credential transmission, Data Fabric supports SSL encryption for HiveServer2. For information about how to configure encryption, see [Hive Encryption](#).

HiveServer2 supports the following authentication methods:

Configure MapR-SASL Authentication for HiveServer 2

About this task

MapR-SASL is available starting with the 1504 release of Hive 0.13 and Hive 1.0. However, the configuration requirements for MapR-SASL differ based on the version of Hive that you have installed:

- As of Hive 0.13-1501, Hive 1.0-1510, and Hive 1.2-1510, MapR-SASL and PAM are enabled by default on a secure cluster; no configuration is required. Complete the steps below if you want HiveServer2 to only accept MapR-SASL authentication.
- In Hive 0.13-1508 and Hive 1.0-1508, MapR-SASL is not the default and must be configured.
- In Hive 0.13-1504 and Hive 1.0-1504, MapR-SASL is the default authentication method when the cluster is secure. No configuration is required.

Procedure

1. Configure the following property in hive-site.xml on each node where HiveServer2 is installed:

Property	Value
hive.server2.authentication	MAPRSASL

```
<property> <name>hive.server2.authentication</name> <value>MAPRSASL</value></property>
```

2. Restart HiveServer2 to apply these changes.

```
maprcli node services -name hs2 -action restart -nodes <comma separated list of nodes>
```

Configure HiveServer2 to use LDAP Authentication

Procedure

1. Configure the following properties in the hive-site.xml file on each node where HiveServer2 is installed:

Property	Value
hive.server2.authentication	LDAP
hive.server2.authentication.ldap.url	The access URL for your LDAP server
hive.server2.authentication.ldap.baseDN	The base LDAP DN for your LDAP server. For example, ou=People, dc=mycompany, dc=com.

Property	Value
hive.server2.authentication.ldap.userDNPattern	User DN Pattern - A DN pattern that can be used to directly login users to the LDAP database. This pattern is used for creating a DN string for "direct" user authentication, where the pattern is relative to the base DN in ldapUrl.

```
<property>
  <name>hive.server2.authentication</name>
  <value>LDAP</value>
</property>
<property>
  <name>hive.server2.authentication.ldap.url</name>
  <value><LDAP URL></value>
</property>
<property>
  <name>hive.server2.authentication.ldap.baseDN</name>
  <value><LDAP Base DN></value>
</property>
```

For generic LDAP servers, you must use:

- a. hive.server2.authentication.ldap.baseDN
- b. hive.server2.authentication.ldap.userDNPattern

However, Active Directory (AD) does not require the above two options, they can be replaced by the following property:

- hive.server2.authentication.ldap.Domain

Property	Value
hive.server2.authentication.ldap.Domain	The active directory domain for your environment.

```
<property>
  <name>hive.server2.authentication.ldap.Domain</name>
  <value><AD Domain Name></value>
</property>
```

2. Restart HiveServer2 to apply these changes.

```
maprcli node services -name hs2 -action restart -nodes <comma separated
list of nodes>
```

Configure HiveServer2 to use PAM Authentication

About this task

You can configure HiveServer2 to use Pluggable Access Modules (PAM). The configuration requirements for PAM differ based on the version of Hive that you have installed.

Hive Version	Default Configuration	Configuration Requirement
--------------	-----------------------	---------------------------

Hive 2.3	1904	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.
	1901	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.
	1808	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.
Hive 2.1	1904	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.
	1901	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.
	1808	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.
	1803	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.

Configure HiveServer2 to explicitly use PAM Authentication

Procedure

1. In the `hive-site.xml` on each HiveServer2 node, set the `hive.server2.authentication` property to PAM:

```
<property>
  <name>hive.server2.authentication</name>
  <value>PAM</value>
</property>
```

2. Restart HiveServer2 to apply these changes:

```
maprcli node services -name hs2 -action restart -nodes <comma-separated
list of nodes>
```

Configure HiveServer 2 to use Custom Authentication

Procedure

1. Create a custom Authenticator class derived from the following interface:

```
public interface PasswdAuthenticationProvider {
    /**
     * The Authenticate method is called by the HiveServer2 authentication
     layer
     * to authenticate users for their requests.
     * If a user is to be granted, return nothing/throw nothing.
     * When a user is to be disallowed, throw an appropriate {@link
     AuthenticationException}.
     *
     * For an example implementation, see {@link
     LdapAuthenticationProviderImpl}.
     *
     * @param user - The username received over the connection request
     * @param password - The password received over the connection request
     * @throws AuthenticationException - When a user is found to be
     * invalid by the implementation
     */
    void Authenticate(String user, String password) throws
    AuthenticationException;
}
```

The [SampleAuthenticator.java](#) on page 4974 code has an example implementation that has stored usernames and passwords.

2. Configure the following properties in the `hive-site.xml` file on each node where HiveServer2 is installed:

Property	Value
hive.server2.authentication	CUSTOM
hive.server2.custom.authentication.class	The authentication class name. For example, <code>hive.server2.custom.authentication.class</code>

```
<property>
<name>hive.server2.authentication</name>
<value>CUSTOM</value>
</property>

<property>
<name>hive.server2.custom.authentication.class</name>
<value>hive.test.SampleAuthenticator</value>
</property>
```

3. Restart Hiveserver2 to apply the changes:

```
maprcli node services -name hs2 -action restart -nodes <comma separated
list of nodes>
```

SampleAuthenticator.java

```
package hive.test;

import java.util.Hashtable;
import javax.security.sasl.AuthenticationException;
import org.apache.hive.service.auth.PasswdAuthenticationProvider;
```

```

/*
javac -cp $HIVE_HOME/lib/hive-service-0.11-mapr.jar
SampleAuthenticator.java -d .
jar cf sampleauth.jar hive
cp sampleauth.jar $HIVE_HOME/lib/.
*/

public class SampleAuthenticator implements PasswdAuthenticationProvider {

    Hashtable<String, String> store = null;

    public SampleAuthenticator () {
        store = new Hashtable<String, String>();
        store.put("user1", "passwd1");
        store.put("user2", "passwd2");
    }

    @Override
    public void Authenticate(String user, String password)
        throws AuthenticationException {

        String storedPasswd = store.get(user);

        if (storedPasswd != null && storedPasswd.equals(password))
            return;

        throw new AuthenticationException("SampleAuthenticator: Error
validating user");
    }
}

```

Configure HiveServer 2 to use Kerberos

About this task

NOTE: You can configure HiveServer2 to use Kerberos authentication. Data Fabric clusters do not provide Kerberos infrastructure. The tips in this section assume a Linux-based Kerberos environment, and the specific commands for your environment may vary. Consult with your Kerberos administrator for assistance.

Enabling HiveServer to use Kerberos authentication requires following steps on each node where HiveServer 2 is installed:

Procedure

1. Create a Kerberos Identity and keytab. You can use the following commands in a Linux-based Kerberos environment to set up the identity and update the keytab file: The `hive.keytab` file must be owned and readable only by the `mapr` user.

```

# kadmin
: addprinc -randkey username/<FQDN@REALM>
: ktadd -k /opt/mapr/conf/hive.keytab username/<FQDN@REALM>

```

2. Configure the following properties in `hive-site.xml` on each node where `hiveserver2` is installed:

v

Property	Value
hive.server2.authentication	KERBEROS
hive.server2.authentication.kerberos.principal	<HiveServer2 Principle. For example, mapr/ FQDN@REALM>
hive.server2.authentication.kerberos.keytab	<The keytab file for the HiverServer2 principle. For example, /opt/mapr/conf/hive.keytab>

```
<property>
  <name>hive.server2.authentication</name>
  <value>KERBEROS</value>
  <description>authenticationtype</description>
</property>
<property>
  <name>hive.server2.authentication.kerberos.principal</name>
  <value>mapr/FQDN@REALM</value>
  <description>HiveServer2 principal. If _HOST is used as the FQDN
portion, it will be replaced with the actual hostname of the running
instance.</description>
</property>
<property>
  <name>hive.server2.authentication.kerberos.keytab</name>
  <value>/opt/mapr/conf/hive.keytab</value>
  <description>Keytab file for HiveServer2 principal</description>
</property>
```

- Reconfigure the following options in `env.sh` (`/opt/mapr/conf/env.sh`) on each node where hiveserver2 is installed:

NOTE: These configurations are listed in the portion of the file that begins with `if [ "$MAPR_SECURITY_STATUS" = "true" ];`. However, you should make the changes in the `/opt/mapr/conf/env_override.sh` file. For more information, see [About env_override.sh](#) on page 3467.

Existing Configuration	Required Configuration
MAPR_HIVE_SERVER_LOGIN_OPTS="-Dhadoop.login=maprsasl_keytab" MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=maprsasl"	MAPR_HIVE_SERVER_LOGIN_OPTS="-Dhadoop.login=hybrid" MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=hybrid"

- Restart HiveServer2 to apply these changes.

```
maprcli node services -name hs2 -action restart -nodes <comma separated
list of nodes>
```

Configure HiveServer 2 Clients to use Kerberos

About this task

When HiveServer 2 is configured to use Kerberos authentication, you must also configure HiveServer2 clients to use Kerberos.

On each node where HiveServer2 clients (not including Beeline) are installed, reconfigure the following option in `env.sh` (`/opt/mapr/conf/env.sh`) file:

Existing Configuration	Required Configuration
<code>MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=maprasl"</code>	<code>MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=hybrid"</code>

NOTE: This configuration is listed in the portion of the file that begins with `if [ "$MAPR_SECURITY_STATUS" = "true" ];`. However, you should make the change in the `/opt/mapr/conf/env_override.sh` file. For more information, see [About env_override.sh](#) on page 3467.

On each node where Beeline is installed, reconfigure the following option in `beeline.sh` (`$hive_home/bin/ext/beeline.sh`) file:

Existing Configuration	Required Configuration
<code>HADOOP_OPTS="\$HADOOP_OPTS\$ {MAPR_HIVE_LOGIN_OPTS}"</code>	<code>HADOOP_OPTS="\$HADOOP_OPTS\$ {KERBEROS_LOGIN_OPTS}"</code>

For more information, see [Connecting to Hive](#) on page 5056.

NOTE: The `MAPR_HIVE_LOGIN_OPTS` and `MAPR_HIVE_SERVER_LOGIN_OPTS` were added in 1504 release of Hive 0.13 and Hive 1.0. If you have Hive 0.13 from a prior release, you do not need to configure these properties. Instead, set `MAPR_ECOSYSTEM_LOGIN_OPTS` and `MAPR_ECOSYSTEM_SERVER_LOGIN_OPTS` to `"-Dhadoop.login=hybrid"` in `/opt/mapr/conf/env.sh`.

Configure HiveServer2 Web UI to use PAM Authentication

About this task

You can configure HiveServer2 web UI to use Pluggable Access Modules (PAM) authentication. The following Hive properties are added to enable PAM authentication for the HiveServer2 web UI:

```
hive.server2.webui.use.pam
Default value: false
Description: If true, the HiveServer2 WebUI will be secured with PAM
```

```
hive.server2.webui.pam.authenticator
Default value: org.apache.hive.http.security.PamAuthenticator
Description: Class for PAM authentication
```

Modifying the hive-site.xml file:

Procedure

Configure the following properties in the `hive-site.xml` file to enable authentication on each node where HiveServer2 is installed:

```
<!-- HS2 web UI PAM -->
<property>
  <name>hive.server2.webui.use.pam</name>
  <value>true</value>
</property>
```

```

<!-- HS2 web UI SSL -->
<property>
  <name>hive.server2.webui.use.ssl</name>
  <value>true</value>
</property>

<property>
  <name>hive.server2.webui.keystore.path</name>
  <value>/opt/mapr/conf/ssl_keystore</value>
</property>

<property>
  <name>hive.server2.webui.keystore.password</name>
  <value><ssl-keystore-password></value>
</property>

```

NOTE: After running `/opt/mapr/server/configure.sh -R`, all properties needed for HiveServer2 Web UI to use PAM authentication is added automatically to `hive-site.xml` on the MapR-SASL secure cluster. Connections to HiveServer2 using ODBC do not support MapR-SASL.

Authentication for WebHCat

You can configure authentication for in-bound client connections to WebHCat. Clients of WebHCat include web browsers. WebHCat is a client of Hive Metastore.

WebHCat supports the following authentication methods:

Configure Kerberos Authentication for WebHCat

About this task

When security features are enabled on your Data Fabric cluster and Kerberos is in use, communications between WebHCat and its clients can use Kerberos with [SPNEGO](#).

To enable WebHCat to use Kerberos, complete the following steps on the node where WebHCat is installed.

Procedure

1. Create the principal `HTTP/<FQDN@REALM>` for WebHCat and add the principal to the keytab file. For example:

```

kadmin: addprinc -randkey HTTP/<FQDN@REALM>
kadmin: xst -k /opt/mapr/HTTP.keytab HTTP/<FQDN>

```

2. Verify the following:

- The principal was added to the `/opt/mapr/conf/HTTP.keytab` file and that the file is only readable by the `mapr` user. For example: `chown mapr /opt/mapr/conf/HTTP.keytab`
- The node where the WebHCat server is running has an HTTP user with a valid `mapr` login password.

3. Add the following section to the `/opt/mapr/hive/hive-<version>/hcatalog/etc/webhcat/webhcat-site.xml` file:

```
<property>
  <name>templeton.kerberos.secret</name>
  <value>secret value</value>
</property>
<property>
  <name>templeton.kerberos.principal</name>
  <value>HTTP/<FQDN@REALM></value>
</property>
<property>
  <name>templeton.kerberos.keytab</name>
  <value>/opt/mapr/conf/HTTP.keytab</value>
</property>
```

4. Add the following section to the `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/core-site.xml` file:

```
<property>
  <name>hadoop.proxyuser.HTTP.groups</name>
  <value>*</value>
  <description>Allow the superuser mapr to impersonate any member of
any group</description>
</property>
<property>
  <name>hadoop.proxyuser.HTTP.hosts</name>
  <value>*</value>
  <description>The superuser can connect from any host to
impersonate a user</description>
</property>
```

5. Start WebHCat. See [Managing the WebHCat Server](#).
6. To test if the connection is working, generate a Kerberos ticket with the `kinit` utility and then run the following command:

```
curl --negotiate -i -u : 'http://<FQDN>:50111/templeton/v1/ddl/database/'
```

Configure Simple Authentication for WebHCat

When the Data Fabric cluster is not secure, simple authentication is enabled for WebHCat. No configuration is required.

Configure PAM Authentication for WebHCat

When the Data Fabric cluster is secure, username and password authentication is enabled for WebHCat. No configuration is required.

Configuring Hive for SCRAM Token Authentication

This topic describes the manual and automatic options to configure Hive for SCRAM token authentication.

Starting from EEP 8.1.0, Hive supports SCRAM token and SCRAM-SHA-256 authentication in HPE Data Fabric.

Table

#	Property	Data Type	Default value	Description
---	----------	-----------	---------------	-------------

Table (Continued)

1	hive.delegation.token.authentication	String	DIGEST	Delegation token authentication method. Possible values are DIGEST, SCRAM
---	--------------------------------------	--------	--------	---

To connect to HiveServer2 on EEP 8.1.0 from Hive client on EEP 8.0.x, set `hive.delegation.token.authentication` property in HPE Data Fabric.

Manually Configuring SCRAM Token Authentication

To configure SCRAM token and SCRAM-SHA-256 authentication, set the following property on `HIVE_HOME/conf/hive-site.xml` file:

```
<property>
  <name>hive.delegation.token.authentication</name>
  <value>SCRAM</value>
</property>
```

The default value for `hive.delegation.token.authentication` is DIGEST.

To use `hive.delegation.token.authentication` for Hive, configure Hadoop for SCRAM:

- Set the value of `hadoop.security.token.authentication.method` property to SCRAM-SHA-256 in `yarn-site.xml` file.
- Set `scram.password` property and ensure encrypted password file is available in file system.

To learn more, see Hadoop documentation.

Auto Configuring SCRAM Token Authentication

Execute `MAPR_HOME/server/configure.sh -R` script on a newly installed MapR-SASL or KERBEROS secured cluster to automatically configure the following authentications:

1. For a FIPS enabled cluster, Hive configures `hive.delegation.token.authentication=SCRAM authentication`.
2. For a non-FIPS cluster if you configure Hadoop with `hadoop.security.token.authentication.method=SCRAM authentication`, Hive configures the SCRAM authentication.
3. For other clusters, Hive configures `hive.delegation.token.authentication=DIGEST authentication`.

For non-secure clusters, Hive configures `hive.delegation.token.authentication=DIGEST authentication`.

You can see `hive.delegation.token.authentication` property in `HIVE_HOME/conf/hive-site.xml` when you execute `configure.sh` command on newly installed cluster.

When you upgrade Hive, the upgrade does not update the value of the set `hive.delegation.token.authentication` property.

Manually set the value of `hive.delegation.token.authentication` property when you change the cluster settings from FIPS to non-FIPS or from non-FIPS to FIPS.

Hive Encryption

When you configure encryption, the thrift messages sent between the Hive Metastore, HiveServer 2, and HiveServer2 clients are encrypted.

When you configure encryption, the thrift messages sent between the Hive Metastore, HiveServer 2, and HiveServer2 clients are encrypted.

Encryption is supported when HiveServer2 has no authentication or when it is configured to use MapR-SASL or Kerberos authentication.

This section contains the following topics:

Configure Encryption with MapR-SASL or Kerberos Authentication

About this task

Complete the following steps on each node where HiveServer2 is installed:

Procedure

1. In `hive-site.xml` file, set the following property:

Property	Value
<code>hive.server2.thrift.sasl.qop</code>	<code>auth-conf</code>

NOTE: As of Hive 0.13-1504 and Hive 1.0-1504, `hive.server2.thrift.sasl.qop` is set to `auth-conf` by default on secure clusters.

```
<property>
  <name>hive.server2.thrift.sasl.qop</name>
  <value>auth-conf</value>
  <description>Sasl QOP value; one of 'auth', 'auth-int' and
  'auth-conf'</description>
</property>
```

2. Restart HiveServer2 to apply these changes.

```
maprcli node services -name hs2 -action restart -nodes <comma separated
list of nodes>
```

Configure Encryption without Authentication

About this task

Complete the following steps on each node where HiveServer2 is installed:

Procedure

1. In `hive-site.xml` file, set the following properties:

Property	Value
<code>hive.server2.use.SSL</code>	<code>true</code>
<code>hive.server2.ssl.keystore</code>	<code><path to keystore file></code>
<code>hive.server2.ssl.keystore.password</code>	<code><password></code>

WARNING: If you specify the password in the `hive-site.xml` file, protect the file with the appropriate file permissions. HiveServer2 automatically prompts for the keystore password during startup when no password is stored in the `hive-site.xml` file.

```
<property>
  <name>hive.server2.use.ssl</name>
  <value>true</value>
  <description>enable/disable SSL communication</description>
</property>
<property>
  <name>hive.server2.ssl.keystore</name>
  <value><path-to-keystore-file></value>
  <description>path to keystore file</description>
</property>

<property>
  <name>hive.server2.ssl.keystore.password</name>
  <value><password></value>
  <description>keystore password</description>
</property>
```

- 2. Restart HiveServer2 to apply these changes.

```
maprcli node services -name hs2 -action restart -nodes <comma separated
list of nodes>
```

Configure HiveServer2 Clients to use Encryption

Based on the encryption method, the requirements for clients to connect to HiveServer2 differ.

- When HiveServer2 uses encryption with MapR-SASL or Kerberos authentication, the client must specify the same sasl qop value that is set for HiveServer2 (auth-conf is the default, recommended option).
- When HiveServer2 uses SSL encryption without authentication, the client must specify a truststore. The `ssl_truststore` file must be copied from the cluster to the client. Specifying a truststore password is optional.

For details, see [Connecting to Hive](#) on page 5056.

Configure the TLS (SSL) Protocol Version in Hive

Beginning with EEPs 6.3.1 and 7.0.0, the default protocol version for TLS (SSL) is TLSv1.2, but you can use the `hive.ssl.protocol.version` property to set a custom value for TLS (SSL).

Setting the TLS (SSL) Protocol Version

To enable the direct configuration of the TLS (SSL) version, Hive provides the following property:

Property	Type	Default Value	Description
hive.ssl.protocol.version	String	TLSv1.2	SSL protocol versions for all Hive servers.

To set a custom value for the TLS (SSL) protocol version in Hive:

- 1. Add the following to the `hive-site.xml` file:

```
<property>
  <name>hive.ssl.protocol.version</name>
```

```
<value><custom_value></value>
</property>
```

In this example, <custom_value> can be one of the following:

- SSLv2
- SSLv3
- SSLv2Hello
- TLSv1
- TLSv1.1
- TLSv1.2

For more information, see the following table:

#	Algorithm Name (TLS/SSL Version)	Description
1	Default	Use the default algorithm.
2	SSL	Supports some versions of SSL; may support other versions.
3	SSLv2	Supports SSL version 2 or later; may support other versions.
4	SSLv3	Supports SSL version 3; may support other versions.
5	TLS	Supports some versions of TLS; may support other versions.
6	TLSv1	Supports RFC 2246: TLS version 1.0 ; may support other versions.
7	TLSv1.1	Supports RFC 4346: TLS version 1.1 ; may support other versions.
8	TLSv1.2	Supports RFC 5246: TLS version 1.2 ; may support other versions.

2. Restart all Hive services.

Special Considerations for Protocol Versions

Note these special considerations for the protocol versions:

- When `hive.ssl.protocol.version` is set to `TLSv1.2`, the protocol supports TLS 1.2. When `hive.ssl.protocol.version` is set to `TLSv1`, the protocol supports TLS versions up to TLS 1.0 (but not TLS 1.1 and 1.2). When `hive.ssl.protocol.version` is set to `TLSv1.1`, the protocol supports versions up to TLS 1.1 (but not TLS 1.2).
- `SSLv2Hello` is not a real encryption protocol. It merely enables clients to find out which encryption protocols are supported by the server to which they connect. As long as `SSLv2Hello` is used only by clients and servers to negotiate a safe protocol, such as `TLSv1.1` or `TLSv1.2`, it does not pose a security risk.

- Hive has a property called `hive.ssl.protocol.blacklist` with a default value of `SSLv2, SSLv3, SSLv2Hello, TLSv1, TLSv1.1`. If you want to enable `TLSv1.1`, for example, you must remove it from the blacklist above. For example:

```
<property>
<name>hive.ssl.protocol.blacklist</name>
<value>SSLv2, SSLv3, SSLv2Hello, TLSv1</value>
</property>

<property>
<name>hive.ssl.protocol.version</name>
<value>TLSv1.1</value>
</property>
```

- If you use the TLS (SSL) protocol version from the blacklist, you will get the following exception when connecting to Hiveserver2 via JDBC:

```
Unknown HS2 problem when communicating with Thrift server.
Error: Could not open client transport with JDBC Uri: jdbc:hive2://
<hostname>:10000/default;auth=maprsasl;ssl=true:
javax.net.ssl.SSLHandshakeException: Received fatal alert:
handshake_failure (state=08S01,code=0)
```

- Empty values are allowed for `hive.ssl.protocol.version`. Hive uses the default value in that case. The same is true for `hive.ssl.protocol.blacklist`.
- The `hive.ssl.protocol.version` property is out of scope for a secure-by-default configuration. This means that it will not appear in the `hive-site.xml` after you use the `Hive configure.sh` script. Nevertheless, the default value of `hive.ssl.protocol.version` is still `TLSv1.2`, and you do not need to set it explicitly.

Hive Password Encryption

EEP 4.0 introduces default configuration for Hive Metastore password encryption using the Data Fabric Installer. The password is stored in the `hive-site.xml` file.

EEP 4.0 introduces default configuration for Hive Metastore password encryption using the Data Fabric Installer. The password is stored in the `hive-site.xml` file.

NOTE: For Hive-2.1 (EEP-5.0.0 and later) and Hive-2.3 (EEP-6.0.0 and later) installed using the Data Fabric Installer, `javax.jdo.option.ConnectionPassword` is automatically encrypted.

```
<property>
<name>javax.jdo.option.ConnectionPassword<name>
<value>{password}<value>
</property>
```

The `hadoop.security.credential.provider.path` configuration property replaces the `javax.jdo.option.ConnectionPassword` property in the `hive-site.xml` file that contains the path to the keystore file created by the Hadoop Credential Provider. Credential providers store and protect passwords out of clear text for the underlying database. By default, the Data Fabric Installer creates the keystore file in the Data Fabric file system. `/user/${MAPR_USER}/hivemetastore.jceks`.

NOTE: Starting from Hive-2.3 EEP 6.0.0, SSL keystore passwords, `hive.server2.webui.keystore.password`, `hive.server2.keystore.password`, and `templeton.keystore.password`, are automatically read from the `/opt/mapr/conf/ssl-client.xml` file without any additional steps from your side. But you can still encrypt them manually and store them in the `*jceks` files.

Reset Data Fabric Installer Default Configuration

To remove changes made by the Data Fabric Installer and reset Hive to its default setting:

1. Open the `hive-site.xml` file.
2. Delete the `hadoop.security.credential.provider.path` property.
3. Add the `javax.jdo.option.ConnectionPassword` property.
4. Save and close the `hive-site.xml` file.

Manual Password Encryption

NOTE: For any user to use Hive, the keystore file requires read permission (644). To limit keystore file access to a smaller number of Hive users, modify permissions as necessary.

ATTENTION: When you wish to run the `hadoop credential` command for provisioning a password or secret to a particular credential store provider, use the `-provider` command line option to explicitly indicate which provider store to use. If a path of multiple providers is given, the first non-transient provider will be used. Note that this provider may or may not be the one that you intended to use.

To encrypt a password manually:

1. Create the keystore file using the Hadoop Credential Provider as follows:

```
hadoop credential create javax.jdo.option.ConnectionPassword -provider
<path-to-keystore>
```

Where `<path-to-keystore>` is `jceks://<file-system-name>/<path-to-keystore>`.

For example, `jceks://maprfs/user/mapr/hivemetastore.jceks`

NOTE: On running the command, you are prompted to enter and re-enter the password to encrypt. Once you provide the password and confirm the password, the `javax.jdo.option.ConnectionPassword` is created and the `org.apache.hadoop.security.alias.JavaKeyStoreProvider` is updated.

2. Delete the `javax.jdo.option.ConnectionPassword` property in the `hive-site.xml` file:

```
<property>
  <name>javax.jdo.option.ConnectionPassword</name>
  <value>{yourpassword}</value>
</property>
```

3. Add the `hadoop.security.credential.provider.path` property to the `/opt/mapr/hive/<hive-release-version>/conf/hive-site.xml` file:

```
<property>
  <name>hadoop.security.credential.provider.path</name>
  <value>jceks://maprfs/user/mapr/hivemetastore.jceks</value>
  <description>specify password to use against metastore database here</
description>
</property>
```

- Restart the Hive services to update the configuration:

```
maprccli node services -name hivemeta -action restart -nodes `hostname -f`
maprccli node services -name hs2 -action restart -nodes `hostname -f`
maprccli node services -name hcat -action restart -nodes `hostname -f`
```

Encrypt the Oozie Database Password

Follow the steps given below to encrypt the Oozie database password:

- Configure Oozie to use a MySQL database as described in [Configure a MySQL Data Store for Oozie](#).
- Optionally, export the Hadoop credential store password as a system variable: \$ export HADOOP_CREDSTORE_PASSWORD=password.
- Add oozie.service.jpaservice.jdbc.password to the jceks keystore:

```
$ hadoop credential create
oozie.service.jpaservice.jdbc.password -provider jceks://path/to/
oozie.jceks
Enter the password:
Enter the password again:
oozie.service.jpaservice.jdbc.password has been successfully created.
org.apache.hadoop.security.alias.JavaKeyStoreProvider has been updated.
```

- Verify that the MySQL password was added:

```
Keystore type: JCEKS
Keystore provider: SunJCE

Your keystore contains 1 entry

Alias name: oozie.service.jpaservice.jdbc.password
Creation date: Apr 11, 2018
Entry type: SecretKeyEntry
```

- Once the jceks file is created, add the hadoop.security.credential.provider.path property to the oozie-site.xml file with the path to the jceks file. The jceks path location can be maprfs or a local file (local-fs).

```
<property>
  <name>hadoop.security.credential.provider.path</name>
  <value>jceks://path/to/oozie.jceks</value>
</property>
```

- Update the password property to use ***** instead of a word-readable password:

```
<property>
  <name>oozie.service.JPAService.jdbc.password</name>
  <value>*****</value>
</property>
```

Hive Authorization

HPE Data Fabric has built-in platform authorization that protects all data regardless of the execution engine. This topic describes alternative authorization modes you can choose to implement.

For more information, refer to [Authorization in Data Fabric](#) on page 908.

In addition to the centralized authorization provided by the HPE Data Fabric, you can use several authorization modes for Hive. The use cases and trade-offs for these authorization modes are described in the sections below.

Understanding Hive Authorization Use Cases

Table Storage Layer and SQL Query Engine are the two primary use cases for client-based authorization protection, delivered as part of the open source project.

Use Case 1: Table Storage Layer

This is the use case for Hive [HCatalog API](#) users.

In this case, Hive provides a table abstraction and metadata for files on storage (typically Data Fabric file system). You have direct access to Data Fabric file system and the metastore server (which provides an API for metadata access).

Data Fabric file system access is authorized through the use of Data Fabric file system [permissions](#). You need to authorize metadata access using Hive configuration.

Use Case 2: SQL Query Engine

This is one of the most common use cases of Hive. This is the "Hive view" of SQL users and BI tools. This use case has the following two subcategories:

- Hive command line users - You have direct access to Data Fabric file system and the Hive metastore, which makes this use case similar to use case 1.
- ODBC/JDBC and other HiveServer2 API users (Beeline CLI is an example) - You have all data or metadata access through HiveServer2. You do not have direct access to Data Fabric file system or the metastore.

OPA Authorization for Hive Metastore (HMS)

Describes the procedure to enable OPA-authorization for HMS.

For Data Lakehouse - Spark and Presto Integration, Hive Metastore (HMS) needs authorization from OPA, to reuse the policies defined for data lakehouse catalog.

Enabling OPA Authorization for HMS

As cluster administrator (mapr user), do the steps that follow:

1. Add `OPAMetaStoreAuthorizer` in `HIVE_HOME/conf/hive-site.xml` file:

```
<property>
    <name>hive.metastore.pre.event.listeners</name>

    <value>org.apache.hadoop.hive ql.security.authorization.plugin.metastore.
    opa.OPAMetaStoreAuthorizer</value>
    <description>Comma separated list of listeners to be invoked
    before metastore events</description>
</property>
```

2. Add OPA endpoint under `hive.metastore.opa.url` in `HIVE_HOME/conf/hive-site.xml` file:

```
<property>
    <name>hive.metastore.opa.url</name>
    <value>OPA_endpoint</value>
    <description>URL for OPA endpoint</description>
</property>
```

3. Restart the HMS by either of the following ways:

- Re-configure by running `/opt/mapr/server/configure.sh -R` command. Or
- Restart only HMS by running `/opt/mapr/bin/maprccli node services -name hivemeta -action restart -nodes hostname` command.

After this, HMS performs authorization check before processing its events.

Disabling OPA Authorization HMS

To disable OPA authorization for HMS, remove `OPAMetaStoreAuthorizer` in `HIVE_HOME/conf/hive-site.xml` file:

```
<property>
    <name>hive.metastore.pre.event.listeners</name>

<value>org.apache.hadoop.hive.ql.security.authorization.plugin.metastore.opa
.OPAMetaStoreAuthorizer</value>
    <description>Comma separated list of listeners to be invoked
before metastore events</description>
</property>
```

Understanding Hive Authorization Modes

Different modes of Hive authorization are available to satisfy different use cases.

Secure by Default Configuration (Storage Based Authorization in the Metastore Server)

Hive default security configuration is the storage based authorization in the Metastore server. Managed by Data Fabric tickets and impersonation level, Hive configurations control the data access and Data Fabric file system permissions act as one source of truth for the table storage access. By enabling storage based authorization in the metastore server, you can use this single source for truth and have a consistent data and metadata authorization policy.

For use cases where the users have direct access to the data, Hive configurations do not control the data access. The Data Fabric file system permissions act as the one source of truth for table storage access. To control metadata access on the metadata objects such as databases, tables, and partitions, Data Fabric file system checks if you have permission to access the corresponding directories on the file system.

You can also protect access through HiveServer2 ([use case 2.2](#)) by ensuring that the queries run as the end user. The `hive.server2.enable.doAs` option should be `true` in the HiveServer2 configuration, this is a default value.

For more information, see [Hive Security Configuration Options](#) on page 4959.

SQL Standards Based Authorization in HiveServer2

Although storage based authorization provides access control at the level of databases, tables, and partitions, it can only control authorization at finer levels such as columns and views for Data Fabric Database tables and not for files because the access control provided by the file system is at the level of directory and files. SQL standards authorization makes authorization possible for files BUT at the expense of not being able to enforce that access from any other tool.

For enabling SQL standards based authorization, refer to [SQL Standards-Based Hive Authorization](#) on page 4989.

Legacy Hive Authorization

Old default authorization is the authorization mode that has been available in earlier versions of Hive. However, this mode does not have a complete access control model, leaving many security gaps unaddressed.

For example, the permissions needed to grant privileges for a user are not defined, and any user can grant themselves access to a table or database.

This model is similar to the SQL standards based authorization mode, in that it provides grant or revoke statement-based access control. However, the access control policy is different from SQL standards based authorization, and they are not compatible. Use of this mode is also supported for Hive command line users. However, for reasons mentioned under the discussion of SQL standards based authorization, it is not a secure mode of authorization for the Hive command line.

Related Links

For information related to Hive authorization modes, see:

- [Storage Based Authorization in the Metastore Server](#)
- [HCatalog Authorization](#)
- [SQL Standard Based Hive Authorization](#)
- [Hive deprecated authorization mode / Legacy Mode](#)
- [Hive security design document](#)
- [Hive security document](#)

SQL Standards-Based Hive Authorization

Using EEP 6.0.0 and later, you can configure SQL standards-based authorization to enable fine grained access control with SQL commands.

The SQL standards-based authorization mode can be used in conjunction with storage-based authorization on the Metastore server. Like the current default authorization in Hive, SQL standards-based authorization is also enforced at query compilation time. To provide security through this option, the client must be secured. You can do this by allowing users access only through HiveServer2, and by restricting the user code and non-SQL commands that can be run. The checks will happen against the user who submits the request, but the query will run as the Hive server user. The directories and files for input data would have read access for this Hive server user. For users who do not need to protect against malicious users, this could potentially be supported through the Hive command line as well.

1. Add the following properties to `hive-site.xml`:

```
<!-- SQL standard based authorization -->
<property>
  <name>hive.server2.enable.doAs</name>
  <value>>false</value>
</property>
<property>
  <name>hive.users.in.admin.role</name>
  <value>mapr</value>
</property>
<property>
  <name>hive.security.metastore.authorization.manager</name>

  <value>org.apache.hadoop.hive.ql.security.authorization.MetaStoreAuthzAPI
  AuthorizerEmbedOnly</value>
</property>
<property>
  <name>hive.security.authorization.manager</name>

  <value>org.apache.hadoop.hive.ql.security.authorization.plugin.sqlstd.SQL
  StdConfOnlyAuthorizerFactory</value>
</property>
```

2. Create a `hiveserver2-site.xml` configuration file:

```
touch /opt/mapr/hive/hive-<version>/conf/hiveserver2-site.xml
```

Add the following properties to the `hiveserver2-site.xml` file:

```
<configuration>
<property>
  <name>hive.security.authorization.manager</name>

  <value>org.apache.hadoop.hive.ql.security.authorization.plugin.sqlstd.SQL
  StdHiveAuthorizerFactory</value>
</property>
<property>
  <name>hive.security.authorization.enabled</name>
  <value>>true</value>
</property>
<property>
  <name>hive.security.authenticator.manager</name>

  <value>org.apache.hadoop.hive.ql.security.SessionStateUserAuthenticator</
  value>
</property>
<property>
  <name>hive.metastore.uris</name>
  <value></value>
</property>
</configuration>
```

3. Change the owner of the `hiveserver2-site.xml` file to `mapr`, and restart Hive services:

```
chown mapr:mapr /opt/mapr/hive/hive-<version>/conf/hiveserver2-site.xml

maprcli node services -name hs2 -action restart -nodes `hostname -f`
maprcli node services -name hivemeta -action restart -nodes `hostname -f`
```

If you are a database administrator and want to run commands such as `create role` and `drop role` or access objects without being given explicit access, you must run the `set role` command.

1. Create a test role:

```
hive> set role admin;
OK
Time taken: 0.02 seconds

hive> create role example_role;
OK
Time taken: 0.099 seconds

hive> show roles;
OK
admin
public
role1
example_role
Time taken: 0.02 seconds, Fetched: 3 row(s)
```

2. Grant access:

```
hive> GRANT example_role to USER testuser;
OK
Time taken: 0.058 seconds

hive> GRANT SELECT on table eg_test to role example_role;
OK
Time taken: 0.146 seconds
```

3. Using the test role, check access:

```
sudo -u mapruser1 hive
```

If there is an access violation, correct it. The following is an example of an access violation error:

```
hive> insert into table eg_test values (4), (5), (6);
FAILED: RuntimeException Cannot create staging directory
'maprfs:///user/hive/warehouse/
eg_test/.hive-staging_hive_2018-06-08_10-24-11_566_5325052587659005252-1'
:
User mapruser1(user id 5001) has been denied access to
create .hive-staging_hive_2018-06-08_10-24-11_566_5325052587659005252-1
```

You can apply access restrictions to all actions except for READ access.

The following are examples of permitted access operations:

- Select:

```
hive> select count (*) from eg_test;
OK
3
Time taken: 2.491 seconds, Fetched: 1 row(s)
```

- Describe:

```
hive> describe extended eg_test;
OK
id                               int

Detailed Table Information
Table(tableName:eg_test, dbName:default, owner:mapr,
createTime:1528453013, lastAccessTime:0, retention:0,
sd:StorageDescriptor(cols:[FieldSchema(name:id, type:int,
comment:null)]),
location:maprfs:/user/hive/warehouse/eg_test,
inputFormat:org.apache.hadoop.mapred.TextInputFormat,
outputFormat:org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat
,
compressed:false, numBuckets:-1, serdeInfo:SerDeInfo(name:null,
serializationLib:org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe,
parameters:{serialization.format=1}), bucketCols:[], sortCols:[],
parameters:{},

skewedColValueLocationMaps:{}),
storedAsSubDirectories:false), partitionKeys:[], parameters:
{totalSize=6, numRows=3, rawDataSize=3,
COLUMN_STATS_ACCURATE={"BASIC_STATS":"true"}, numFiles=1,
transient_lastDdlTime=1528453046}, viewOriginalText:null,
viewExpandedText:null, tableType:MANAGED_TABLE, rewriteEnabled:false)
Time taken: 0.12 seconds, Fetched: 3 row(s)
```

- Show columns:

```
hive> SHOW COLUMNS from eg_test;
OK
id
Time taken: 0.049 seconds, Fetched: 1 row(s)
```

NOTE: For more information about privileges required for Hive operations, see the [open source documentation](#).

Configure Hive Metastore to use Storage-Based Authorization

Describes how to enable storage-based authorization (SBA) for the Hive Metastore server.

Storage-based authorization controls access to the data using HDFS permissions (HDFS ACL). To control access to metadata objects, such as databases, tables, and partitions, it checks if you have permission on the corresponding directories on the file system.

To enable storage-based authorization for the Hive Metastore server, set these properties in `hive-site.xml`:

Property	Value	Description
hive.metastore.pre.event.listeners	org.apache.hadoop.hive.ql.security.authorization.AuthorizationPreEventListener*	Turns on Metastore security. A MetaStorePreEventListener that performs authorization or authentication checks on the metastore side. Note that this can only perform authorization checks on defined metastore PreEventContexts, such as the adding, dropping, and altering of databases, tables, and partitions.

Property	Value	Description
hive.security.metastore.authorization.manager	org.apache.hadoop.hive.ql.security.authorization.StorageBasedAuthorizationProvider* Note: <ul style="list-style-type: none"> The StorageBasedAuthorizationProvider setting first appeared on the Metastore side only in Hive 0.10.0. With Hive 0.12.0 and later, it can also run on the client side. Starting from EEP 6.1.0, hive.security.metastore.authorization.manager is set to the StorageBasedAuthorizationProvider value by default. 	StorageBasedAuthorizationProvider - Specifies use of an HDFS permission-based model (recommended) for the Metastore-side authorization provider. DefaultHiveMetastoreAuthorizationProvider - This default implements the standard Hive grant/revoke model.
hive.security.metastore.authenticator.manager	org.apache.hadoop.hive.ql.security.HadoopDefaultMetastoreAuthenticator (default)	Authentication manager class name to be used in the metastore for authentication. The user-defined authenticator should implement the org.apache.hadoop.hive.ql.security.HiveAuthenticationProvider interface.
hive.security.metastore.authorization.auth.reads	true (default)	Default value (does not appear in hive-site.xml file). Set to true, Metastore authorization also performs a read authorization check (first supported in Hive 0.14.0).
hive.server2.enable.doAs	true (default)	Use for protected access through HiveServer2.

* In secure clusters, the Data Fabric "secure-by-default" configuration implicitly configures these properties in the hive-site.xml file.

SBA configuration example in hive-site.xml File

```

<property>
  <name>hive.security.metastore.authorization.manager</name>

  <value>org.apache.hadoop.hive.ql.security.authorization.StorageBasedAuthorizationProvider</value>
</property>

<property>
  <name>hive.security.metastore.authenticator.manager</name>

  <value>org.apache.hadoop.hive.ql.security.HadoopDefaultMetastoreAuthenticator</value>
</property>

<property>
  <name>hive.security.metastore.authorization.auth.reads</name>
  <value>true</value>
</property>

<property>

```

```

    <name>hive.server2.enable.doAs</name>
    <value>true</value>
  </property>

  <property>
    <name>hive.metastore.pre.event.listeners</name>

    <value>org.apache.hadoop.hive.ql.security.authorization.AuthorizationPreEventListener</value>
  </property>

```

If you use storage-based authorization, you still need to use one of the following authorization models to protect actions within the HiveServer2:

- [Configuring Fallback Hive Authorizer](#) on page 4994
- [SQL Standards-Based Hive Authorization](#) on page 4989

Fallback Hive Authorizer

Fallback Hive Authorizer is used by Hive DDL (Data Definition Language) tasks for access control and for checking authorization from `Driver.doAuthorization()`.

It is designed to prevent [CVE-2018-11777](#).

In addition to the centralized authorization provided by HPE Data Fabric, you can use several authorization modes for Hive. The use cases and trade-offs for these authorization modes are described in the sections below.

Configuring Fallback Hive Authorizer

You can enable protection of actions within the HiveServer2 instance by using the Fallback Authorizer.

About this task

Use the Fallback Authorizer when you want to protect access for Hive clients (JDBC/ODBC, Beeline CLI, and other HiveServer2 API users).

To enable Fallback Authorization for Hive clients, set these properties in the `hive-site.xml` file:

Property	Value	Description
<code>hive.security.authorization.enabled</code>	<code>true*</code>	Enable or disable the Hive client authorization.
<code>hive.security.authorization.manager</code>	<code>org.apache.hadoop.hive.ql.security.authorization.plugin.fallback.FallbackHiveAuthorizerFactory*</code>	Class name for the Hive client authorization manager.
<code>hive.users.in.admin.role</code>	<code>mapr*</code>	Comma-separated list of users who need to be added to the admin role. Note that a user who belongs to the admin role needs to run the <code>set role</code> command before getting the privileges of the admin role, as the admin role is not in current roles by default.

* In secure clusters, the HPE Data Fabric "Secure-by-Default" configuration implicitly configures the Fallback Authorizer in the `hive-site.xml` file.

Fall Back Authorizer applies the following restrictions:

- Allows set only for selected allowlist parameters.
- Disallows dfs commands except for admin.

- Disallows local file location in SQL statements except for admin.
- Disallows ADD JAR, COMPILE, and TRANSFORM statements.

Fallback Authorization Configuration Example in hive-site.xml File

```
<property>
  <name>hive.security.authorization.enabled</name>
  <value>true</value>
</property>

<property>
  <name>hive.security.authorization.manager</name>

<value>org.apache.hadoop.hive.ql.security.authorization.plugin.fallback.Fall
backHiveAuthorizerFactory</value>
</property>

<property>
  <name>hive.users.in.admin.role</name>
  <value>mapr</value>
</property>
```

Action Restrictions with Fallback Hive Authorizer

After enabling Fallback Hive Authorizer, you can perform action restriction operations.

Procedure

- Disallow local file location in SQL statements for all except the administrator.
- Allow set for selected white list parameters.
- Disallow dfs commands for all except the administrator.
- Disallow ADD JAR statements for all except the administrator.
- Disallow COMPILE statements for all except the administrator.
- Disallow TRANSFORM statements.

Using a White List with Fallback Hive Authorizer

You can add an exception to Fallback Hive Authorizer restrictions using the `hive.security.authorization.sqlstd.confwhitelist.append` property.

About this task

The `hive.security.authorization.sqlstd.confwhitelist` property is list of comma-separated Java regexes that you can append to. Appending to this list instead of updating the original list means that you can append to the default set by SQL-standard authorization instead of replacing it entirely.

You can modify the configurations parameters that match these regexes when SQL-standard authorization is enabled.

To get the default value, use the `set <param>` command. The `hive.conf.restricted.list` checks are still enforced after the white-list check.

An example of a white-list configuration is as follows:

```
<property>
  <name>hive.security.authorization.sqlstd.confwhitelist.append</name>
```

```
<value>hive.reloadable.aux.jars.path</value>
</property>
```

Procedure

- After adding this configuration to the `hive-site.xml` file, execute the following command:

```
set hive.reloadable.aux.jars.path=/path/to/jar
```

Considerations for Hive on JDK 17 and later

Considerations for Hive on JDK 17 and later

 **IMPORTANT:** If you have installed JDK 17 or later with DEP 10.0.0 or later, no action is necessary. As of DEP 10.0.0, Hive auto-configuration completes the following:

- The MapR configuration tool adds the required properties to `hive-site.xml` automatically.
- `configure.sh` adds the Hadoop options to `hive-env.sh` automatically.

If you are running a version of DEP earlier than version 10.0.0, you must configure these settings manually.

Proceed to the next section if you have installed JDK versions earlier than JDK 17.

Considerations for Hive on versions earlier than JDK 17

When configured correctly, Hive works on versions earlier than DK 17, but it is still possible to encounter an error such as:

```
Caused by: java.lang.reflect.InaccessibleObjectException: <detailed
description>: module java.base does not "opens <module name>" to unnamed
module
```

Here is an example of the error:

```
Caused by: java.lang.reflect.InaccessibleObjectException: Unable to make
field private final int java.time.LocalDate.year accessible: module
java.base does not "opens java.time" to unnamed module
```

To fix the issue, you must add the following fix:

```
--add-opens java.base/<module name>=ALL-UNNAMED
```

For example:

```
--add-opens java.base/java.time=ALL-UNNAMED
```

You must add the fix in two places:

- HADOOP_OPTS variable in the `hive-env.sh` conf file
- `mapreduce.map.java.opts`, `mapreduce.reduce.java.opts`,
`yarn.app.mapreduce.am.command-opts` properties of the `hive-site.xml` conf file

Here is an example of making the fix:

1. Add the following entry to the `hive-env.sh` file:

```
export HADOOP_OPTS="-XX:+IgnoreUnrecognizedVMOptions --add-opens
java.base/java.time=ALL-UNNAMED"
```

2. Add the following properties to the `hive-site.xml` file:

```
<property>
  <name>mapreduce.map.java.opts</name>
  <value>-Xmx900m --add-opens java.base/
java.lang=ALL-UNNAMED -XX:+UseParallelGC --add-opens java.base/
java.net=ALL-UNNAMED --add-opens java.base/
java.nio=ALL-UNNAMED --add-opens java.base/
java.util=ALL-UNNAMED --add-opens java.base/
java.util.concurrent.atomic=ALL-UNNAMED --add-opens java.base/
java.util.regex=ALL-UNNAMED --add-opens java.base/java.time=ALL-UNNAMED</
value>
</property>
<property>
  <name>mapreduce.reduce.java.opts</name>
  <value>-Xmx2560m --add-opens java.base/
java.lang=ALL-UNNAMED -XX:+UseParallelGC --add-opens java.base/
java.net=ALL-UNNAMED --add-opens java.base/
java.nio=ALL-UNNAMED --add-opens java.base/
java.util=ALL-UNNAMED --add-opens java.base/
java.util.concurrent.atomic=ALL-UNNAMED --add-opens java.base/
java.util.regex=ALL-UNNAMED --add-opens java.base/java.time=ALL-UNNAMED</
value>
</property>
<property>
  <name>yarn.app.mapreduce.am.command-opts</name>
  <value>-Xmx2560m --add-opens java.base/
java.lang=ALL-UNNAMED -XX:+UseParallelGC --add-opens java.base/
java.net=ALL-UNNAMED --add-opens java.base/
java.nio=ALL-UNNAMED --add-opens java.base/
java.util=ALL-UNNAMED --add-opens java.base/
java.util.concurrent.atomic=ALL-UNNAMED --add-opens java.base/
java.util.regex=ALL-UNNAMED --add-opens java.base/java.time=ALL-UNNAMED</
value>
</property>
```

[Installing Hive](#) on page 302

This topic includes instructions for using package managers to download and install Hive from the EEP repository.

Integrating Hive

Hive and HPE Data Fabric Database Integration

You can create HPE Data Fabric Database binary tables from Hive that can be accessed by both Hive and HPE Data Fabric Database. You can run Hive queries on HPE Data Fabric Database binary tables, convert existing HPE Data Fabric Database binary tables into Hive-HPE Data Fabric Database tables, and run Hive queries on those tables as well.

Install and Configure Hive

Procedure

1. Install and configure Hive if it is not already installed. See [Installing Hive](#) on page 302 for details.

2. Execute the `jps` command and ensure that all relevant Hadoop, Data Fabric, and Zookeeper processes are running. Example:

```
$ jps
1549 jenkins.war
15051 QuorumPeerMain
30935 Jps
15551 CommandServer
15293 ResourceManager
15328 NodeManager
15131 WardenMain
```

3. Open the `hive-site.xml` file with your favorite editor, or create a `hive-site.xml` file if it doesn't already exist:

```
$ cd $HIVE_HOME
$ vi conf/hive-site.xml
```

4. Copy the following XML code and paste it into the `hive-site.xml` file.

NOTE: If you already have an existing `hive-site.xml` file with a configuration element block, just copy the property element block code below and paste it inside the configuration element block in the `hive-site.xml` file. Be sure to use the correct values for the paths to your auxiliary JARs and ZooKeeper IP numbers.

Example configuration:

```
configuration>

<property>
  <name>hive.aux.jars.path</name>
  <value>file:///opt/mapr/hive/hive-<version>/lib/
hive-hbase-handler-<version>-mapr.jar,
file:///opt/mapr/hbase/hbase-<version>/lib/
hbase-client-<version>-mapr.jar, file:///opt/mapr/hbase/
hbase-<version>/lib/hbase-server-<version>-mapr.jar,file:///opt/mapr/
hbase/hbase-<version>/lib/hbase-protocol-<version>-mapr.jar,file:///opt/
mapr/zookeeper/zookeeper-<version>/zookeeper-<version>.jar</value>
  <description>A comma separated list (with no spaces) of the jar files
required for Hive-HBase integration</description>
</property>

<property>
  <name>hbase.zookeeper.quorum</name>
  <value>xx.xx.x.xxx,xx.xx.x.xxx,xx.xx.x.xxx</value>
  <description>A comma separated list (with no spaces) of the IP
addresses of all ZooKeeper servers in the cluster.</description>
</property>

<property>
  <name>hbase.zookeeper.property.clientPort</name>
  <value>5181</value>
  <description>The Zookeeper client port. The MapR default clientPort is
5181.</description>
</property>

</configuration>
```

5. Save and close the `hive-site.xml` file.

Results

If you have successfully completed all of the steps in this section, you're ready to begin the tutorial in the next section.

Getting Started with Hive and HPE Data Fabric Database Binary Integration

In this tutorial we will:

- Create a Hive table
- Populate the Hive table with data from a text file
- Query the Hive table
- Create a Hive-HPE Data Fabric Database table
- Introspect the Hive-HPE Data Fabric Database table from the HBase shell
- Populate the Hive-HPE Data Fabric Database table with data from the Hive table
- Query the Hive-HPE Data Fabric Database table from Hive
- Convert an existing HPE Data Fabric Database table into a Hive-MapR table

Be sure that you have successfully completed all of the steps in [Installing Hive](#) on page 302 and review the HPE Data Fabric Database topics before beginning this Getting Started tutorial.

This Getting Started tutorial is based on the Hive-HBase Integration section of the Apache Hive Wiki. However, please note that there are some significant differences.

Create a Hive table with two columns

Change to your Hive installation directory if you're not already there and start Hive:

```
$ cd $HIVE_HOME
$ bin/hive
```

Execute the CREATE TABLE command to create the Hive pokes table

```
hive> CREATE TABLE pokes (foo INT, bar STRING);
```

To see if the pokes table has been created successfully, execute the SHOW TABLES command

```
hive> SHOW TABLES;
OK
pokes
Time taken: 0.74 seconds
```

The pokes table appears in the list of tables. **Populate the Hive pokes table with data:**

The kv1.txt file is provided in the \$HIVE_HOME/examples/files directory. Execute the LOAD DATA LOCAL INPATH command to populate the Hive pokes table with data from the kv1.txt file.

```
hive> LOAD DATA LOCAL INPATH './examples/files/kv1.txt' OVERWRITE INTO
TABLE pokes;
```

A message appears confirming that the table was created successfully, and the Hive prompt reappears:

```
Copying data from file:
...
OK
```

```
Time taken: 0.278 seconds
hive>
```

Execute a SELECT query on the Hive pokes table

```
hive> SELECT * FROM pokes WHERE foo = 98;
```

The SELECT statement executes, runs a MapReduce application, and prints the application output:

```
OK
98      val_98
98      val_98
Time taken: 18.059 seconds
```

The output of the SELECT command displays two identical rows because there are two identical rows in the Hive pokes table with a key of 98.

WARNING:

Hive tables can have multiple identical keys. As we will see shortly, HPE Data Fabric Database tables cannot have multiple identical keys, only unique keys.

Create a Hive-HPE Data Fabric Database table

Enter these four lines of code at the Hive prompt:

```
hive> CREATE TABLE mapr_table_1(key int, value string)
> STORED BY 'org.apache.hadoop.hive.hbase.HBaseStorageHandler'
> WITH SERDEPROPERTIES ("hbase.columns.mapping" = ":key,cf1:val")
> TBLPROPERTIES ("hbase.table.name" = "/user/mapr/xyz");
```

After a brief delay, a message appears confirming that the table was created successfully:

```
OK
Time taken: 5.195 seconds
```

Note: The TBLPROPERTIES command is not required, but those new to Hive-HPE Data Fabric Database integration may find it easier to understand what's going on if Hive and HPE Data Fabric Database use different names for the same table.

In this example, Hive will recognize this table as "mapr_table_1" and HPE Data Fabric Database will recognize this table as "xyz".

Start the HBase shell

Keeping the Hive terminal session open, start a new terminal session for HBase, then start the HBase shell:

```
$ cd $HBASE_HOME
$ bin/hbase shell
HBase Shell; enter 'help<RETURN>' for list of supported commands.
Type "exit<RETURN>" to leave the HBase Shell
Version 0.90.4, rUnknown, Wed Nov  9 17:35:00 PST 2011

hbase(main):001:0>
```

Execute the list command to see a list of HBase tables

```
hbase(main):001:0> list
TABLE
```

```
/user/mapr/xyz
1 row(s) in 0.8260 seconds
```

HBase recognizes the Hive-HPE Data Fabric Database table named xyz in directory /user/mapr. This is the same table known to Hive as mapr_table_1.

Display the description of the /user/mapr/xyz table in the HBase shell

```
hbase(main):004:0> describe "/user/mapr/xyz"
DESCRIPTION                               ENABLED
{NAME => '/user/mapr/xyz', FAMILIES => [{NAME => 'cf1', DATA_B true
LOCK_ENCODING => 'NONE', BLOOMFILTER => 'NONE', REP

]}
1 row(s) in 0.0240 seconds
```

From the Hive prompt, insert data from the Hive table pokes into the Hive-HPE Data Fabric Database table mapr_table_1

```
hive> INSERT OVERWRITE TABLE mapr_table_1 SELECT * FROM pokes WHERE foo=98;
...
2 Rows loaded to mapr_table_1
OK
Time taken: 13.384 seconds
```

Query mapr_table_1 to see the data we have inserted into the Hive-HPE Data Fabric Database table

```
hive> SELECT * FROM mapr_table_1;
OK
98      val_98
Time taken: 0.56 seconds
```

Even though we loaded two rows from the Hive pokes table that had the same key of 98, only one row was actually inserted into mapr_table_1. This is because mapr_table_1 is a HPE Data Fabric Database table, and although Hive tables support duplicate keys, HPE Data Fabric Database tables only support unique keys. HPE Data Fabric Database tables arbitrarily retain only one key, and silently discard all of the data associated with duplicate keys.

Convert a pre-existing HPE Data Fabric Database table to a Hive-HPE Data Fabric Database table

To convert a pre-existing HPE Data Fabric Database table to a Hive-HPE Data Fabric Database table, enter the following four commands at the Hive prompt.

Note that in this example the existing HPE Data Fabric Database table is my_mapr_table in directory /user/mapr.

```
hive> CREATE EXTERNAL TABLE mapr_table_2(key int, value string)
> STORED BY 'org.apache.hadoop.hive.hbase.HBaseStorageHandler'
> WITH SERDEPROPERTIES ("hbase.columns.mapping" = "cf1:val")
> TBLPROPERTIES("hbase.table.name" = "/user/mapr/my_mapr_table");
```

Now we can run a Hive query against the pre-existing HPE Data Fabric Database table /user/mapr/my_mapr_table that Hive sees as mapr_table_2:

```
hive> SELECT * FROM mapr_table_2 WHERE key > 400 AND key < 410;
Total MapReduce jobs = 1
Launching Job 1 out of 1
```

```

Number of reduce tasks is set to 0 since there's no reduce operator
...
OK
401      val_401
402      val_402
403      val_403
404      val_404
406      val_406
407      val_407
409      val_409
Time taken: 9.452 seconds

```

Optimizing HPE Data Fabric Database Tables Search by ID

Starting from the 1904 release (EEP 6.0.2, EEP 6.1.1, and EEP 6.2.0), search by ID is supported with Hive HPE Data Fabric Database JSON tables.

About this task

Property of Optimization

Prerequisites

The property name is `hive.mapr.db.json.fetch.by.id.task.conversion` and the value has a boolean type and by default is set to `true`, which means it is enabled.

Procedure

- To disable optimization, set `hive.mapr.db.json.fetch.by.id.task.conversion` to `false`.

Conditions for Optimization

Procedure

- This optimizer is designed for queries such as:

```

SELECT *
FROM <mapr_db_json_table>
WHERE _id = <constant_string_value>;

```

or:

```

SELECT *
FROM <mapr_db_json_table>
WHERE _id = <constant_string_value> AND (<condition_1>) AND
(<condition_2>) ... AND (<condition_N>);

```

or:

```

SELECT *
FROM <mapr_db_json_table>
WHERE <Constant false operator>

```

where `_id` is a key column of HPE Data Fabric Database JSON table. It provides usage of the `findById()` method of the HPE Data Fabric Database JSON table. The following functionality is not supported:

- joins
- group by

- distinct
- lateral view
- subquery
- create table as select (CTAS) or insert
- analyze
- single source

The predicate is not actually a part of the filter, so it is ignored by push down:

```
SELECT * FROM t WHERE (CASE WHEN _id = 'value_a' THEN 2 ELSE 4 END) > 3;
```

Using Optimization

Procedure

1. Consider the following HPE Data Fabric Database JSON table:

```
CREATE TABLE t(doc_id string, col1 string, col2 string) STORED BY  
'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'  
TBLPROPERTIES("maprdb.table.name" = "/user/mapr/  
db_json_table", "maprdb.column.id" = "doc_id");
```

2. Run the EXPLAIN command:

```
EXPLAIN SELECT col1 FROM t WHERE doc_id='id_004';
```

3. The following output is produced:

```

STAGE DEPENDENCIES:
  Stage-0 is a root stage

STAGE PLANS:
  Stage: Stage-0
    MapR DB JSON Fetch By Id Operator
    limit: -1
    Processor Tree:
      TableScan
      alias: t_small
      filterExpr: (doc_id = 'id_004') (type: boolean)
      Statistics: Num rows: 1 Data size: 0 Basic stats: PARTIAL Column
      stats: NONE
      Filter Operator
      predicate: (doc_id = 'id_004') (type: boolean)
      Statistics: Num rows: 1 Data size: 0 Basic stats: PARTIAL Column
      stats: NONE
      Select Operator
      expressions: col1 (type: string)
      outputColumnNames: _col0
      Statistics: Num rows: 1 Data size: 0 Basic stats: PARTIAL Column
      stats: NONE
      ListSink

```

An important part of a query plan is that it shows if optimization is available for the query:

```

STAGE PLANS:
  Stage: Stage-0
    MapR DB JSON Fetch By Id Operator

```

Connecting Using Hive HPE Data Fabric Database JSON Connector

This section describes the Hive connector for HPE Data Fabric Database JSON table.

About this task

The Hive connector supports the creation of HPE Data Fabric Database based Hive tables. You can create a JSON table on HPE Data Fabric Database and load CSV data and/or JSON files to HPE Data Fabric Database using the connector. HPE Data Fabric Database based Hive tables can be:

- Queried just like file system based Hive tables.
- Combined with file system based Hive tables in joins and sub-queries.

NOTE: If you use Drill to query Hive tables based on MapR Database tables, you can [enable the native Drill reader](#), which can improve query performance.

The following table lists the Hive data type and the corresponding (supported) HPE Data Fabric Database OJAI type:

Hive Type	HPE Data Fabric Database OJAI Type
BOOLEAN	BOOLEAN
BINARY	BINARY
TINYINT	BYTE
DATE	DATE
DOUBLE	DOUBLE

Hive Type	HPE Data Fabric Database OJAI Type
FLOAT	FLOAT
INT	INT
BIGINT	LONG
SMALLINT	SHORT
STRING	STRING
TIMESTAMP	TIMESTAMP

The Hive connector for HPE Data Fabric Database JSON table also supports the use of the following complex data types:

- map
- array
- struct

NOTE: The HPE Data Fabric Database JSON tables do not support ACID transactions, bucketing, and alteration.

Creating a HPE Data Fabric Database JSON Table and Hive Table Using Hive

Procedure

- To create a table, run the command similar to the following:

NOTE: The required properties are shown in bold.

```
CREATE TABLE primitive_types (
  id string,
  bo boolean,
  d double,
  da date,
  f double,
  i int,
  s string,
  ts timestamp)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/tbl", "maprdb.column.id" = "id");
```

Here:

- The `maprdb.table.name`, `maprdb.column.id` and `STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'` are mandatory properties.
- The value for `maprdb.column.id` column should be of type string or binary.

To create a Hive table that exists on HPE Data Fabric Database, specify `EXTERNAL` in the table DDL. If the table created is `EXTERNAL`, when the table is dropped, only its metadata is deleted; the underlying HPE Data Fabric Database data remains intact. On the other hand, if the table is not `EXTERNAL`, dropping the table deletes both the metadata associated with the table and the underlying HPE Data Fabric Database data.

For example, suppose a JSON table named `/apps/my_users` with the following values:

```
{"_id":"001","first_name":"John","last_name":"Doe","age":34}
{"_id":"002","first_name":"Jack","last_name":"Smith","age":26}
```

To create a Hive table over existing HPE Data Fabric Database JSON table:

```
CREATE EXTERNAL TABLE primitive_types (
  user_id string,
  first_name string,
  last_name string,
  age int)
STORED BY 'org.apache.hadoop.hive.mapadb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("mapadb.table.name" = "/apps/my_users","mapadb.column.id" =
"user_id");
```

Now, because table `primitive_types` points to HPE Data Fabric Database table, you can perform ETL query similar to file system based Hive tables:

```
SELECT COUNT(*) FROM test_external;
SELECT MAX(age) AS label FROM test_external;
...
```

Loading CSV Data to HPE Data Fabric Database JSON Table

Procedure

1. Create intermediate table.

For example:

```
CREATE TABLE stage(id STRING, name STRING, age INT) ROW FORMAT DELIMITED
FIELDS TERMINATED BY ',';
```

2. Load data to table.

For example:

```
LOAD DATA INPATH '/data' into table stage;
```

3. Create HPE Data Fabric Database table in Hive.

For example:

```
CREATE TABLE users(id STRING, name STRING, age INT)
STORED BY 'org.apache.hadoop.hive.mapadb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("mapadb.table.name" = "/users","mapadb.column.id" = "id");
```

4. Insert data through stage table.

For example:

```
INSERT INTO TABLE users select id, name, age from stage;
```

Loading JSON Files to HPE Data Fabric Database JSON Table

Procedure

1. Add SerDe JAR for JSON.

For example:

```
add jar /opt/mapr/hive/hive-<version>/hcatalog/share/hcatalog/
hive-hcatalog-core-<version>-mapr.jar
```

2. Create intermediate table.

For example:

```
CREATE EXTERNAL TABLE stage(id string, name string, age int)
ROW FORMAT SERDE 'org.apache.hive.hcatalog.data.JsonSerDe'
STORED AS TEXTFILE;
```

3. Load data in stage table.

For example:

```
LOAD DATA INPATH '/data' into table stage;
```

NOTE: If there is a key in the JSON file that starts with "_" (for example, "_id"), then treat the names as literals upon creating the schema and query using the same literal syntax. For example, specify `\_id` string without any special serde properties. Then in the query, use `select `_id` from sometable;` Alternatively, you can use 'org.openx.data.jsonserde.JsonSerDe' and add `WITH SERDEPROPERTIES ("mapping.id" = "_id")` to your table definition.

4. Create HPE Data Fabric Database table in Hive.

For example:

```
CREATE TABLE users(id STRING, name STRING, age INT)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/users", "maprdb.column.id" = "id");
```

5. Insert data through stage table.

For example:

```
INSERT INTO TABLE users select id, name, age from stage;
```

If there is a key in your JSON file that starts with "_" (for example, "_id"), treat the names as literals upon creating the schema and also query using the same literal syntax. In the above example, it would look like `\_id` string without any special serde properties for it. Then, use again in query as shown below:

```
select `_id` from sometable;
```

Alternatively, use `org.openx.data.jsonserde.JsonSerDe` and add `WITH SERDEPROPERTIES ("mapping.id" = "_id")` to your table definition.

Example

Refer to [Hive MapR Database JSON Connector Tutorial](#) for a connector example.

Understanding the UPDATE Statement

Starting with EEP 6.0.0 (Hive 2.3), EEP 5.0.1 (Hive 2.1), EEP 4.1.2, and EEP 3.0.4, the UPDATE statement is supported with Hive HPE Data Fabric Database JSON tables.

You can use the UPDATE statement to update primitive, complex, and complex nested data types in HPE Data Fabric Database JSON tables, using the Hive connector.

Updating Primitive Data Types

This section describes how to use the UPDATE statement to update primitive data types in HPE Data Fabric Database JSON tables, using the Hive connector.

Procedure

1. Create a HPE Data Fabric Database JSON table and a Hive table:

```
CREATE TABLE simple_types_update (
>>>>>>> Incorporated edit comments
  doc_id string,
  bo boolean,
  d double,
  da date,
  f float,
  i int,
  s string,
  ts timestamp,
  ti tinyint,
  bi bigint,
  si smallint,
  bin binary)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/"
simple_types_update", "maprdb.column.id" = "doc_id");
```

2. Insert data into the table:

```
INSERT INTO TABLE simple_types_update VALUES ('1', true, 124.14,
'2017-11-29', 9192.12,
214566190, 'text', '2017-03-17 00:14:13', 125, 9223372036854775806,
23434, "binary string");
```

3. Run the UPDATE command on the table:

```
UPDATE simple_types_update
SET da = '2018-12-11',
bo = FALSE,
f = 91.777
WHERE doc_id = '1';
```

4. Verify that the data is inserted in both Hive and HPE Data Fabric Database JSON tables.

- Verifying Hive table data:

```
hive> SELECT * FROM simple_types_update;

1      false      124.14      2018-12-11      91.777      214566190      text
2017-03-17 00:14:13      125      9223372036854775806      23434      binary
string
```

- Verifying HPE Data Fabric Database JSON table data:

```
find '/simple_types_update'

{"_id":"1","bi":{"$numberLong":9223372036854775806},"bin":
{"$binary":"YmluYXJ5IHNoZmluZWAAAAAAAAA=="},
"bo":false,"d":124.14,"da":{"$dateDay":"2018-12-11"},
"f":{"$numberFloat":91.777},"i":{"$numberInt":214566190},
"s":"text","si":{"$numberShort":23434},"ti":{"$numberByte":125},"ts":
{"$date":"2017-03-17T00:14:13.000Z"}}
```

Updating Complex Data Types

This section describes how to use the UPDATE statement to update complex data types in HPE Data Fabric Database JSON tables, using the Hive connector.

Procedure

- Create a HPE Data Fabric Database JSON table and a Hive table:

```
CREATE TABLE complex_types_update (
  doc_id string,
  info MAP<STRING, INT>,
  pets ARRAY<STRING>,
  user_info STRUCT<name:STRING, surname:STRING, age:INT, gender:STRING>)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/"
complex_types_update","maprdb.column.id" = "doc_id");
```

- Insert data into the table:

```
INSERT INTO TABLE complex_types_update SELECT '1', map('age', 28),
array('Cat', 'Cat', 'Cat'),
named_struct('name', 'Santa', 'surname', 'Claus','age', 1000,'gender',
'MALE');
```

- Run the UPDATE command on the table:

```
UPDATE complex_types_update SET
info = map('year', 32),
pets = array('Dog', 'Cat', 'Pig'),
user_info = named_struct('name', 'Vasco', 'surname', 'da Gama','age',
558,'gender', 'MALE')
WHERE doc_id = '1';
```

- Verify that the data is inserted in both Hive and HPE Data Fabric Database JSON tables.

- Verifying Hive table data:

```
hive> SELECT * FROM complex_types_update;

1      {"year":32}      ["Dog","Cat","Pig"]
{"name":"Vasco","surname":"da Gama","age":558,"gender":"MALE"}
```

- Verifying HPE Data Fabric Database JSON table data:

```
find '/complex_types_update'

{"_id":"1","info":{"year":{"$numberInt":32}}, "pets":
["Dog","Cat","Pig"],"user_info":{"age":{"$numberInt":558},
"gender":"MALE","name":"Vasco","surname":"da Gama"}}
```

Updating Complex Nested Data Types

This section describes how to use the UPDATE statement to update complex nested data types in HPE Data Fabric Database JSON tables, using the Hive connector.

Procedure

1. Create a HPE Data Fabric Database JSON table and a Hive table using Hive:

```
CREATE TABLE complex_nested_data_type_update
(
    entry STRING,
    num INT,
    postal_addresses MAP <STRING,
    struct
<USER_ID:STRING, ADDRESS:STRING, ZIP:STRING, COUNTRY:STRING>>
)
stored BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
tblproperties
(
    "maprdb.table.name" = "/complex_nested_data_type_update",
    "maprdb.column.id" = "entry"
);
```

2. Insert data into the table:

```
INSERT INTO TABLE complex_nested_data_type_update
SELECT '001', '1',
MAP ( 'Bill',
Named_struct ('user_id', '1', 'address', '3205 Woodlake ct', 'zip',
'45040', 'country', 'USA'));
```

3. Run the UPDATE command on the table by updating the COUNTRY value in map(struct):

```
UPDATE complex_nested_data_type_update
SET postal_addresses = MAP ('Bill',
Named_struct ('user_id', '1', 'address', '3205 Woodlake ct', 'zip',
'45040', 'country', 'Hun'))
WHERE entry = '001';
```

4. Verify that the data is inserted in both Hive and HPE Data Fabric Database JSON tables.

- Verifying Hive table data:

```
hive> SELECT * FROM complex_nested_data_type_update;

001      1      {"Bill":{"user_id":"1","address":"3205 Woodlake
ct","zip":"45040","country":"Hun"}}
```

- Verifying HPE Data Fabric Database JSON table data:

```
find '/complex_nested_data_type_update'
{"_id":"001","num":{"$numberInt":1},"postal_addresses":{"Bill":
{"address":"3205 Woodlake
ct","country":"Hun","user_id":"1","zip":"45040"}}}
```

UPDATE Statement Limitations

This section describes the features that the UPDATE statement does not support.

The UPDATE statement has the following known limitations:

- The UPDATE statement is fully supported only for primitive data types (see [Connecting to HPE Data Fabric Database](#)).
- The UPDATE statement is partly supported for complex data types; you can replace only the whole value of a complex type with new a value.
- You cannot update the `maprdb.column.id` value.

Understanding the INSERT INTO Statement

This section describes how to use the INSERT INTO statement to insert or overwrite rows in nested HPE Data Fabric Database JSON tables, using the Hive connector.

- [Single-row insert](#) on page 5011
- [Multiple-row insert](#) on page 5013
- [Overwriting data](#) on page 5016

NOTE: The output shown in these examples is for illustration only; actual Hive CLI output varies, depending on your specific situation.

Single-row insert

You can use the INSERT INTO statement to insert a single table row into a nested HPE Data Fabric Database table using one of two methods.

For example, imagine that you have the following Hive HPE Data Fabric Database JSON table, `nested_data_insert`:

```
CREATE TABLE nested_data_insert
(
  entry STRING,
  num INT,
  postal_addresses MAP <STRING,
  struct <USER_ID:STRING, ADDRESS:STRING, ZIP:STRING, COUNTRY:STRING>>
)
stored BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
tblproperties
(
  "maprdb.table.name" = "/nested_data_insert",
  "maprdb.column.id" = "entry"
);
```

- You can insert the new row into your table by using a dummy table:

```
WITH dummy_table AS
  (SELECT '001' AS KEY,
    '1' AS num,
    MAP ('Adam',
      Named_struct ('user_id', '1', 'address', '3205 Woodlake
ct', 'zip', '45040', 'country', 'Usa'),
      'Wilfred',
      Named_struct ('user_id', '2', 'address', '777 Brockton
Avenue', 'zip', '34000', 'country', 'Ita')) AS postal_addresses)
INSERT INTO nested_data_insert
SELECT *
FROM dummy_table;
```

- Alternatively, you can insert the new row into your table by using a SELECT statement:

```
INSERT INTO TABLE nested_data_insert
SELECT '002',
  '2',
  MAP ('Bill',
    Named_struct ('user_id', '1', 'address', '328 Virginia Ave',
'zip', '54956', 'country', 'Bol'),
    'Stiv',
    Named_struct ('user_id', '2', 'address', 'Schererville',
'zip', '46375', 'country', 'Efi'));
```

After you insert data, you should verify that the data is inserted in both Hive and HPE Data Fabric Database JSON tables:

- Verify the insertion into the Hive table by using the SELECT * FROM syntax.

```
SELECT * FROM nested_data_insert;
```

Sample output:

Table

entry	num	postal_address				
			USER_ID	ADDRESS	ZIP	COUNTRY
001	1	Adam	1	3205 Woodlake ct	45040	Usa
		Wilfred	2	777 Brockton Avenue	34000	Ita
002	2	Bill	1	328 Virginia Ave	54956	Bol
		Stiv	2	Schererville	46375	Efi

- Verify the insertion into the HPE Data Fabric Database JSON table data using the `find` statement:

```
find '/nested_data_insert'

{
  "Adam": {
    "user_id": "1",
    "address": "3205 Woodlake ct",
    "zip": "45040",
    "country": "Usa"
  },
  "Wilfred": {
    "user_id": "2",
    "address": "777 Brockton Avenue",
    "zip": "34000",
    "country": "Ita"
  }
}

{
  "Bill": {
    "user_id": "1",
    "address": "328 Virginia Ave",
    "zip": "54956",
    "country": "Bol"
  },
  "Stiv": {
    "user_id": "2",
    "address": "Schererville",
    "zip": "46375",
    "country": "Efi"
  }
}
```

Multiple-row insert

Now imagine that you want to insert three rows of data into `nested_data_insert`.

- You can insert the new rows into your table by using a dummy table:

```
WITH dummy_table AS
  (SELECT '003' AS KEY,
    '3' AS num,
    MAP ('Rony',
      Named_struct ('user_id', '1', 'address', '4333 Backer
str', 'zip', '12311', 'country', 'Hun')) AS postal_addresses
    UNION ALL SELECT '004' AS KEY,
      '4' AS num,
      MAP ('Ivan',
        Named_struct ('user_id', '1', 'address', '833
Bridle Avenue', 'zip', '95111', 'country', 'CA')) AS postal_addresses
    UNION ALL SELECT '005' AS KEY,
      '5' AS num,
      MAP ('Ivan',
        Named_struct ('user_id', '1', 'address', '664
Devon Ave', 'zip', '92021', 'country', 'Tog')) AS postal_addresses)
INSERT INTO nested_data_insert
SELECT *
FROM dummy_table;
```

- Alternatively, you can insert the new rows into your table by using a SELECT statement:

```
INSERT INTO TABLE nested_data_insert
SELECT '006',
      '6',
      MAP ('Rony',
           Named_struct ('user_id', '1', 'address', '150 National City',
                        'zip', '91950', 'country', 'Hun'))
UNION ALL
SELECT '007',
      '7',
      MAP ('Tomason',
           Named_struct ('user_id', '1', 'address', '272 Ocean Circle' ,
                        'zip', '92801', 'country', 'CA'))
UNION ALL
SELECT '008',
      '8',
      MAP ('Davin',
           Named_struct ('user_id', '1', 'address', '81 Augusta Ave',
                        'zip', '93905', 'country', 'CA'));
```

After you insert data, you should verify that the data is inserted in both Hive and HPE Data Fabric Database JSON tables:

- Verify the insertion into the Hive table by using the SELECT * FROM syntax.

```
SELECT * FROM nested_data_insert WHERE entry > '002' ;
```

Sample output:

Table

entry	num	postal_address				
			USER_ID	ADDRESS	ZIP	COUNTRY
003	3	Rony	1	4333 Backer str	12311	Hun
004	4	Ivan	1	833 Bridle Avenue	95111	CA
005	5	Ivan	1	664 Devon Ave.	92021	Tog
006	6	Rony	1	150 National City	91950	Hun
007	7	Tomason	1	272 Ocean Circle	92801	CA
008	8	Davin	1	81 Augusta Ave	93905	CA

- Verify the insertion into the HPE Data Fabric Database JSON table data using the find statement:

```
find '/nested_data_insert'

{
  "_id": "003",
  "num": {
    "$numberInt": 3
  },
  "postal_addresses": {
    "Rony": {
      "address": "4333 Backer str",
      "country": "Hun",
      "user_id": "1",
      "zip": "12311"
    }
  }
}

{
  "_id": "004",
  "num": {
    "$numberInt": 4
  },
  "postal_addresses": {
    "Ivan": {
      "address": "833 Bridle Avenue",
      "country": "CA",
      "user_id": "1",
      "zip": "95111"
    }
  }
}

{
  "_id": "005",
  "num": {
    "$numberInt": 5
  },
  "postal_addresses": {
    "Ivan": {
      "address": "664 Devon Ave",
      "country": "Tog",
      "user_id": "1",
      "zip": "92021"
    }
  }
}

{
  "_id": "006",
  "num": {
    "$numberInt": 6
  },
  "postal_addresses": {
    "Rony": {
      "address": "150 National City",
      "country": "Hun",
      "user_id": "1",
      "zip": "91950"
    }
  }
}

{
  "_id": "007",
  "num": {
```

```

        "$numberInt": 7
      },
      "postal_addresses": {
        "Tomason": {
          "address": "272 Ocean Circle",
          "country": "CA",
          "user_id": "1",
          "zip": "92801"
        }
      }
    }
  },
  {
    "_id": "008",
    "num": {
      "$numberInt": 8
    },
    "postal_addresses": {
      "Davin": {
        "address": "81 Augusta Ave",
        "country": "CA",
        "user_id": "1",
        "zip": "93905"
      }
    }
  }
}

```

Overwriting data

Still using sample table `nested_data_insert`, you can use the `INSERT` statement on a dummy table to overwrite one or more complete rows.

For example, to overwrite the first row in `nested_data_insert` (001) with new values, use the following syntax:

```

WITH dummy_table AS
(SELECT '001' AS KEY,
 '1' AS num,
 MAP ('newAdam',
 Named_struct ('user_id', '1', 'address', 'newAdress', 'zip', 'newZip',
 'country', 'newCountry')) AS postal_addresses)
INSERT INTO nested_data_insert
SELECT *
FROM dummy_table;

```

After you overwrite data, you should verify that the data is changed in both Hive and HPE Data Fabric Database JSON tables:

- Verify the data into the Hive table by using the `SELECT * FROM` syntax.

```
hive> SELECT * FROM nested_data_insert WHERE entry = '001';
```

Sample output:

Table

entry	num	postal_address				
			USER_ID	ADDRESS	ZIP	COUNTRY
001	1	newAdam	1	newAddress	newZip	newCountry

- Verify the data in the HPE Data Fabric Database JSON table data using the `findbyid` statement:

```
findbyid '/nested_data_insert' --id 001

{
  "_id": "001",
  "num": {
    "$numberInt": 1
  },
  "postal_addresses": {
    "newAdam": {
      "address": "newAddress",
      "country": "newCountry",
      "user_id": "1",
      "zip": "newZip"
    }
  }
}
```

For another example, imagine that you want to overwrite 003 and 004 rows in `nested_data_insert` with new values:

```
WITH dummy_table AS (
  SELECT '003' AS KEY,
  '3' AS num,
  MAP ('newName1',
  Named_struct ('user_id', '1', 'address', 'newAdress1', 'zip', 'newZip1',
  'country', 'newCountry1')) AS postal_addresses
  UNION ALL
  SELECT '004' AS KEY,
  '4' AS num,
  MAP ('newName2',
  Named_struct ('user_id', '1', 'address', 'newAdress2', 'zip', 'newZip2',
  'country', 'newCountry2')) AS postal_addresses)
INSERT INTO nested_data_insert
SELECT * FROM dummy_table;
```

After you overwrite the data, you should verify that the data is changed in both Hive and HPE Data Fabric Database JSON tables.

- Verify the data in the Hive table by using the `SELECT * FROM` syntax.

```
hive> SELECT * FROM nested_data_insert WHERE entry IN ('003', '004');
```

Sample output:

Table

entry	num	postal_address				
			USER_ID	ADDRESS	ZIP	COUNTRY
003	3	newName1	1	newAddress1	newZip1	newCountry1
004	4	newName2	1	newAddress2	newZip2	newCountry2

Verify the data in the HPE Data Fabric Database JSON table data using the `findbyid` statement:

```
findbyid '/nested_data_insert' --id 003
{
  "_id": "003",
  "num": {
```

```

        "$numberInt": 3
      },
      "postal_addresses": {
        "newName1": {
          "address": "newAdress1",
          "country": "newCountry1",
          "user_id": "1",
          "zip": "newZip1"
        }
      }
    }
  },
  findbyid '/nested_data_insert' --id 004
  {
    "_id": "004",
    "num": {
      "$numberInt": 4
    },
    "postal_addresses": {
      "newName2": {
        "address": "newAdress2",
        "country": "newCountry2",
        "user_id": "1",
        "zip": "newZip2"
      }
    }
  }
}

```

WARNING: If you exclude columns both from the SELECT statement in your INSERT statement and from the table schema, the value of this column changes to NULL.

Finally, imagine that you want to overwrite the first row in `nested_data_insert` (001) with new values and overwrite the `num` column to NULL:

```

WITH dummy_table AS
(SELECT '001' AS KEY,
MAP ('newAdam',
Named_struct ('user_id', '1', 'address', 'newAdress', 'zip', 'newZip',
'country', 'newCountry')) AS postal_addresses)
INSERT INTO nested_data_insert (entry, postal_addresses)
SELECT * FROM dummy_table;

```

After you overwrite data, you should verify that the data is changed in both Hive and HPE Data Fabric Database JSON tables.

- Verify the data in the Hive table by using the SELECT * FROM syntax.

```
hive> SELECT * FROM nested_data_insert WHERE entry = '001';
```

Sample output:

Table

entry	num	postal_address				
			USER_ID	ADDRESS	ZIP	COUNTRY
001	NULL	newAdam	1	newAddress	newZip	newCountry

- Verify the data in the HPE Data Fabric Database JSON table (num row is not present):

```
findbyid '/nested_data_insert' --id 001

{
  "_id": "001",
  "postal_addresses": {
    "newAdam": {
      "address": "newAddress",
      "country": "newCountry",
      "user_id": "1",
      "zip": "newZip"
    }
  }
}
```

Understanding the MERGE Statement

You can use the MERGE statement to perform record-level INSERT and UPDATE operations efficiently within Hive tables.

The MERGE statement can be a key tool for Data Fabriccluster data management. It is based on ANSI-standard SQL.

The following scenarios can help you understand how to use the MERGE statement:

- [Simple merge.maprdb.column.id is the join key](#) on page 5019
- [Simple merge.maprdb.column.id is not the join key](#) on page 5020
- [DELETE syntax in the MERGE statement](#) on page 5020
- [Multiple source rows match a given target row \(cardinality violation\)](#) on page 5021
- [Merge on mixed data types](#) on page 5022
- [Merge into external HPE Data Fabric Database JSON tables](#) on page 5023
- [Merge into partitioned HPE Data Fabric Database JSON tables](#) on page 5023
- [Merge into temporary HPE Data Fabric Database JSON tables](#) on page 5023

Simple merge.maprdb.column.id is the join key

Consider merging the following example source and target tables:

Table

id	first_name	last_name	age
001	Dorothei	Hogward	7777
002	Alex	Bowee	7777
088	Robert	Dowson	25

Table

id	first_name	last_name	age
001	John	Smith	45
002	Michael	Watson	27
003	Den	Brown	33

You can use the following SQL-standard MERGE statement:

```
MERGE into customer_db_json_target trg
USING customer_source src
ON src.id = trg.id
WHEN MATCHED THEN UPDATE SET age = src.age
WHEN NOT MATCHED THEN
INSERT VALUES (src.id, src.first_name, src.last_name, src.age);
```

The result is:

id	first_name	last_name	age
001	John	Smith	7777
002	Michael	Watson	7777
003	Den	Brown	33
088	Robert	Dowson	25

NOTE: The age column is updated and a new id column is inserted.

Simple merge.maprdb.column.id is not the join key

Merging when merge.maprdb.column is not the join key is not recommended.

DELETE syntax in the MERGE statement

This section describes how to use the DELETE syntax in the MERGE statement for HPE Data Fabric Database JSON tables. Included are examples of usage and limitations.

Consider two tables: `tgt` which is the target table of the MERGE statement, and `src`, which is the source table from which data will be taken. Both tables use `MapRDBJsonStorageHandler` to store data. The following table shows the initial contents of the `tgt` table:

Table

id	Value
1	AAA
2	BBB
3	CCC
4	DDD
5	EEE

The following table shows the initial contents of the `src` table:

Table

id	Value
1	AAA
222	BBB---
3	CCC
444	DDD---
5	EEE

The following merge statement contains a `WHEN MATCHED THEN DELETE` clause. It means that if the `id` from the `tgt` table equals the `id` from the `src` table, the row is removed from the `tgt` table. When the value of `id` does not match, a new row is inserted into the `tgt` table:

```
MERGE INTO tgt
USING src ON tgt.id=src.id
WHEN MATCHED THEN DELETE
WHEN NOT MATCHED THEN INSERT VALUES (src.id, src.value);
```

The following table shows the result of the merge:

Table

id	Value
2	BBB
222	BBB---
4	DDD
444	DDD---

Here we removed rows with `id` 1, 3, and 5 from the `tgt` table because they existed in the `src` table, and they matched values from the `tgt` table. We did not touch rows with `id` 2 and 4, because there were no such values in the `src` table. We inserted new rows with `id` values 222 and 444 because they existed in the `src` table and did not exist in the `tgt` table.

Limitations

The preceding solution has three limitations:

1. Subqueries are not supported as a source when `DELETE` is used.
2. The source table should be a HPE Data Fabric Database JSON table when deletion is used in a `MERGE` operator.
3. The `DELETE` operator is not supported with additional conditions after `WHEN MATCHED`. Use either a single `UPDATE` or `DELETE`.

Limitation #3 means that queries like the following are not supported:

```
MERGE INTO tgt
USING src
ON tgt._id = src._id
WHEN MATCHED AND [boolean expression1] THEN DELETE
WHEN MATCHED AND [boolean expression2] THEN UPDATE
WHEN NOT MATCHED THEN INSERT
```

Multiple source rows match a given target row (cardinality violation)

Consider merging the two tables `customer_db_json` and `customer_new`:

Table

id	first_name	last_name	age
001	John	Smith	45
002	Michael	Watson	27
003	Den	Brown	33

And:

Table

id	first_name	last_name	age
001	Dorothi	Hogward	77
001	Dorothi	Hogward	77
088	Robert	Dowson	25

To MERGE customer_new and customer_db_json:

```

MERGE INTO customer_db_json trg
USING customer_new src ON src.id = trg.id
WHEN MATCHED THEN UPDATE
SET first_name = src.first_name,
    last_name = src.last_name
WHEN NOT MATCHED THEN INSERT VALUES
(src.id, src.first_name, src.last_name, src.age);

```

This example causes an exception because of duplicate values in the id column in the customer_new table:

```

Caused by: org.apache.hadoop.hive.ql.metadata.HiveException: Error
evaluating cardinality_violation(_col0)

```

To avoid cardinality violation, set `hive.merge.cardinality.check=false`, but in this case the result is unpredictable because there is no rule that defines the order of duplicated data that will be inserted by using the MERGE statement.

Merge on mixed data types

The merge operation also supports mixed data types, such as arrays, maps, and structures.

Consider two tables mixed_types_source and mixed_types_target:

Table

doc_id	user_info
1	{"name": "Brandon", "surname": "Lee", "age": 31, "gender": "MALE"}
2	{"name": "Johnson", "surname": "Fall", "age": 23, "gender": "MALE"}
3	{"name": "Mary", "surname": "Dowson", "age": 11, "gender": "FEMALE"}
4	{"name": "Paul", "surname": "Rodgers", "age": 41, "gender": "MALE"}

And:

Table

id	user_info
1	{"name": "Lexx", "surname": "Comfuzer", "age": 31, "gender": "MALE"}

To merge mixed_types_source and mixed_types_target:

```

MERGE INTO mixed_types_target trg
USING mixed_types_source src
ON src.doc_id = old.doc_id
WHEN MATCHED THEN UPDATE
SET user_info = src.user_info

```

```
WHEN NOT MATCHED THEN INSERT VALUES
(src.doc_id, src.user_info);
```

The result is:

Table

id	first_name
1	{"name": "Brandon", "surname": "Lee", "age": 31, "gender": "MALE"}
2	{"name": "Johnson", "surname": "Fall", "age": 23, "gender": "MALE"}
3	{"name": "Mary", "surname": "Dowson", "age": 11, "gender": "FEMALE"}
4	{"name": "Paul", "surname": "Rodgers", "age": 41, "gender": "MALE"}

Note that you cannot update only a part of a complex structure field. For example, suppose you have a structure stored as one field in a Hive table:

```
{"name": "Johnson", "surname": "Fall", "age": 23, "gender": "MALE"}
```

You cannot update only the age field in the structure. You can only replace all values of the structure with new ones. For details, see [Understanding the UPDATE Statement](#) on page 5007.

Merge into external HPE Data Fabric Database JSON tables

The MERGE operator is also available for external HPE Data Fabric Database JSON tables. You can use the MERGE statement to insert and update values in external Data Fabric database JSON table targets.

Merge into partitioned HPE Data Fabric Database JSON tables

Partitioned HPE Data Fabric Database JSON tables are not supported.

Merge into temporary HPE Data Fabric Database JSON tables

The MERGE operator is also available for temporary HPE Data Fabric Database JSON tables. Use temporary tables as target tables for merge. No additional syntax is needed.

Understanding the DELETE FROM Operation

In EEP 6.3.1 and later, you can use the DELETE FROM operation with HPE Data Fabric Database JSON tables.

Delete All Data from a Table

To delete all data from a HPE Data Fabric DatabaseJSON table use the following operator:

```
DELETE FROM <table_name>;
```

Example. In this example we create a table, insert data, and delete all rows:

```
DROP TABLE IF EXISTS customer;
CREATE TABLE customer(doc_id STRING, first_name STRING, last_name STRING)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/customer", "maprdb.column.id" =
"doc_id");
INSERT INTO TABLE customer VALUES ("001", "Max", "Born"), ("002", "Demmy",
"John"), ("003", "Robby", "Smart");
SELECT doc_id, first_name, last_name FROM customer;
```

Table

doc_id	first_name	last_name
001	Max	Born
002	Demmy	John
003	Robby	Smart

The following query gives an empty set. Deletions are supported only for HPE Data Fabric Database JSON tables and transactional tables.

```
DELETE FROM customer;
SELECT doc_id, first_name, last_name FROM customer;
```

Example. In this example, we try to delete data from a non-transactional and non-Data Fabric Database JSON table:

```
DROP TABLE IF EXISTS simple_data;
CREATE TABLE simple_data (id INT);
INSERT INTO TABLE simple_data VALUES (1), (2), (3);
DELETE FROM simple_data;
```

The result is:

```
FAILED: SemanticException Operation is not supported. Table is nor ACID
neither MapRDBJSON
```

Delete a Single Row from a Table

To delete a single row from a HPE Data Fabric Database JSON table, use the following syntax:

```
DELETE FROM <table_name> WHERE <id> = <value>;
```

Where:

<table_name> is the HPE Data Fabric Database JSON table.

<id> is a key column of the Data Fabric Database JSON table. It corresponds to the `maprdb.column.id` property.

<value> is the value to be deleted.

Example. In this example, we create a table, insert data, and delete a single row:

```
DROP TABLE IF EXISTS customer;
CREATE TABLE customer(doc_id STRING, first_name STRING, last_name STRING)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/customer", "maprdb.column.id" =
"doc_id");
INSERT INTO customer VALUES ("001", "Max", "Born"), ("002", "Demmy",
"John"), ("003", "Robby", "Smart");
SELECT doc_id, first_name, last_name FROM customer;
```

Table

doc_id	first_name	last_name
001	Max	Born
002	Demmy	John
003	Robby	Smart

The following query deletes a single row using the WHERE clause:

```
DELETE FROM customer WHERE doc_id = "002";
SELECT doc_id, first_name, last_name FROM customer;
```

Table

doc_id	first_name	last_name
001	Max	Born
003	Robby	Smart

Note. Deletions are supported only for key columns of HPE Data Fabric Database JSON tables.

Example. In this example, we try to use a column other than a key column of the Data Fabric Database JSON table in deletion.

```
DROP TABLE IF EXISTS customer;
CREATE TABLE customer(doc_id STRING, first_name STRING, last_name STRING)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/customer", "maprdb.column.id" =
"doc_id");
INSERT INTO customer VALUES ("001", "Max", "Born"), ("002", "Demmy",
"John"), ("003", "Robby", "Smart");
SELECT doc_id, first_name, last_name FROM customer;
```

Column first_name is not the key column of the table.

```
DELETE FROM customer WHERE first_name = "Max";
```

The result is:

```
FAILED: SemanticException Deletion over column first_name is forbidden. Use
only key column of MapR Db Json table: doc_id
```

Delete Several Rows from a Table

To delete several rows from a table, use the following syntax:

```
DELETE FROM <table_name> WHERE <id> IN (<value1>, <value2>, ...);
```

Where:

<table_name> is the HPE Data Fabric Database JSON table.

<id> is a key column of the MapR Database JSON table. It corresponds to the maprdb.column.id property.

<value1>, <value2>, are values to be deleted.

Example. In this example, we create a table, insert data, and delete several rows:

```
DROP TABLE IF EXISTS customer;
CREATE TABLE customer(doc_id STRING, first_name STRING, last_name STRING)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/customer", "maprdb.column.id" =
"doc_id");
INSERT INTO TABLE customer VALUES ("001", "Max", "Born"), ("002", "Demmy",
"John"), ("003", "Robby", "Smart");
SELECT doc_id, first_name, last_name FROM customer;
```

Table

doc_id	first_name	last_name
001	Max	Born
002	Demmy	John
003	Robby	Smart

The following query deletes several rows using the WHERE ... IN clause:

```
DELETE FROM customer WHERE doc_id IN ("001", "002");
SELECT doc_id, first_name, last_name FROM customer;
```

Table

doc_id	first_name	last_name
003	Robby	Smart

Delete All Rows in a Table Except Listed Rows

To delete all rows from a table except a listed row, use the following syntax:

```
DELETE FROM <table_name> WHERE <id> NOT IN (<value1>, <value2>, ...);
```

Where:

<table_name> is the HPE Data Fabric Database JSON table.

<id> is a key column of the MapR Database JSON table. It corresponds to the maprdb.column.id property.

<value1>, <value2>, are values to be preserved.

Example. In this example, we create a table, insert data, and delete all rows except the listed rows:

```
DROP TABLE IF EXISTS customer;
CREATE TABLE customer(doc_id STRING, first_name STRING, last_name STRING)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/customer", "maprdb.column.id" =
"doc_id");
INSERT INTO TABLE customer VALUES ("001", "Max", "Born"), ("002", "Demmy",
"John"), ("003", "Robby", "Smart");
SELECT doc_id, first_name, last_name FROM customer;
```

Table

doc_id	first_name	last_name
001	Max	Born
002	Demmy	John
003	Robby	Smart

The following query deletes all rows except the listed rows:

```
DELETE FROM customer WHERE doc_id NOT IN ("003");
SELECT doc_id, first_name, last_name FROM customer;
```

Table

doc_id	first_name	last_name
003	Robby	Smart

Limitations of the DELETE FROM Operation

The following are three limitations of the current implementation:

- The current implementation does not support arbitrary conditions in the WHERE clause of the DELETE statement even if a key column is used.

Example. In this example, DELETE FROM is used with an arbitrary condition:

```
DELETE FROM customer WHERE doc_id == "003" OR doc_id <> "005";
```

The result is:

```
FAILED:
      SemanticException This condition is not supported for MapR Db
      Json deletions. Supported
      WHERE clauses are: <id> = value, <id> IN (value1, value2, ...),
      <id> NOT IN (value1, value2,
      ...)
```

- The current implementation does not support subqueries in the WHERE clause.
- The current implementation does not support deletions in the MERGE statement.

Hive and HBase Integration

You can create HBase tables from Hive that can be accessed by both Hive and HBase. This allows you to run Hive queries on HBase tables. You can also convert existing HBase tables into Hive-HBase tables and run Hive queries on those tables as well.

Install and Configure Hive and HBase

Procedure

1. Install and configure Hive if it is not already installed. See [Installing Hive](#) on page 302.
2. Install and configure HBase if it is not already installed. See [Installing HBase](#) on page 297.
3. Run the jps command, and ensure that all relevant Hadoop, HBase and Zookeeper processes are running:

```
$ jps
21985 HRegionServer
1549 jenkins.war
15051 QuorumPeerMain
30935 Jps
15551 CommandServer
15698 HMaster
15293 ResourceManager
15328 NodeManager
15131 WardenMain
```

Getting Started with Hive-HBase Integration

In this tutorial you will:

- Create a Hive table
- Populate the Hive table with data from a text file
- Query the Hive table
- Create a Hive-HBase table
- Introspect the Hive-HBase table from HBase
- Populate the Hive-Hbase table with data from the Hive table
- Query the Hive-HBase table from Hive
- Convert an existing HBase table into a Hive-HBase table

Be sure that you have successfully completed all the steps in the Install and Configure Hive and HBase section before beginning this Getting Started tutorial. This Getting Started tutorial closely parallels the Hive-HBase Integration section of the Apache Hive Wiki, and thanks to Samuel Guo and other contributors to that effort.

Create a Hive table with two columns:

Change to your Hive installation directory if you're not already there and start Hive:

```
$ cd $HIVE_HOME
$ bin/hive
```

Execute the CREATE TABLE command to create the Hive pokes table:

```
hive> CREATE TABLE pokes (foo INT, bar STRING);
```

To see if the pokes table has been created successfully, execute the SHOW TABLES command:

```
hive> SHOW TABLES;
OK
pokes
Time taken: 0.74 seconds
```

The pokes table appears in the list of tables.

Populate the Hive pokes table with data

Execute the LOAD DATA LOCAL INPATH command to populate the Hive pokes table with data from the kv1.txt file.

The kv1.txt file is provided in the \$HIVE_HOME/examples directory.

```
hive> LOAD DATA LOCAL INPATH './examples/files/kv1.txt' OVERWRITE INTO
TABLE pokes;
```

A message appears confirming that the table was created successfully, and the Hive prompt reappears:

```
Copying data from file:
...
OK
Time taken: 0.278 seconds
hive>
```

Execute a SELECT query on the Hive pokes table:

```
hive> SELECT * FROM pokes WHERE foo = 98;
```

The SELECT statement executes, runs a MapReduce application, and prints the job output:

```
OK
98      val_98
98      val_98
Time taken: 18.059 seconds
```

The output of the SELECT command displays two identical rows because there are two identical rows in the Hive pokes table with a key of 98. Note: This is a good illustration of the concept that Hive tables can have multiple identical keys. As we will see shortly, HBase tables cannot have multiple identical keys, only unique keys.

To create a Hive-HBase table, enter these four lines of code at the Hive prompt:

```
hive> CREATE TABLE hbase_table_1(key int, value string)
> STORED BY 'org.apache.hadoop.hive.hbase.HBaseStorageHandler'
> WITH SERDEPROPERTIES ("hbase.columns.mapping" = ":key,cf1:val")
> TBLPROPERTIES ("hbase.table.name" = "xyz");
```

After a brief delay, a message appears confirming that the table was created successfully:

```
OK
Time taken: 5.195 seconds
```

Note: The TBLPROPERTIES command is not required, but those new to Hive-HBase integration may find it easier to understand what's going on if Hive and HBase use different names for the same table.

In this example, Hive will recognize this table as "hbase_table_1" and HBase will recognize this table as "xyz".

Start the HBase shell:

Keeping the Hive terminal session open, start a new terminal session for HBase, then start the HBase shell:

```
$ cd $HBASE_HOME
$ bin/hbase shell
HBase Shell; enter 'help<RETURN>' for list of supported commands.
Type "exit<RETURN>" to leave the HBase Shell
Version 0.90.4, rUnknown, Wed Nov  9 17:35:00 PST 2011

hbase(main):001:0>
```

Execute the list command to see a list of HBase tables:

```
hbase(main):001:0> list
TABLE
xyz
1 row(s) in 0.8260 seconds
```

HBase recognizes the Hive-HBase table named xyz. This is the same table known to Hive as hbase_table_1.

Display the description of the xyz table in the HBase shell:

```
hbase(main):004:0> describe "xyz"
DESCRIPTION
```

```

    ENABLED
    {NAME => 'xyz', FAMILIES => [{NAME => 'cf1', BLOOMFILTER => 'NONE',
    REPLICATI true
    ON_SCOPE => '0', COMPRESSION => 'NONE', VERSIONS => '3', TTL =>
    '2147483647', BL
    OCKSIZE => '65536', IN_MEMORY => 'false', BLOCKCACHE => 'true'}}}
1 row(s) in 0.0190 seconds

```

From the Hive prompt, insert data from the Hive table pokes into the Hive-HBase table hbase_table_1

```

hive> INSERT OVERWRITE TABLE hbase_table_1 SELECT * FROM pokes WHERE foo=98;
...
2 Rows loaded to hbase_table_1
OK
Time taken: 13.384 seconds

```

Query hbase_table_1 to see the data we have inserted into the Hive-HBase table:

```

hive> SELECT * FROM hbase_table_1;
OK
98      val_98
Time taken: 0.56 seconds

```

Even though we loaded two rows from the Hive pokes table that had the same key of 98, only one row was actually inserted into hbase_table_1. This is because hbase_table_1 is an HBASE table, and although Hive tables support duplicate keys, HBase tables only support unique keys. HBase tables arbitrarily retain only one key, and will silently discard all the data associated with duplicate keys.

Convert a pre-existing HBase table to a Hive-HBase table

To convert a pre-existing HBase table to a Hive-HBase table, enter the following four commands at the Hive prompt.

Note that in this example the existing HBase table is my_hbase_table.

```

hive> CREATE EXTERNAL TABLE hbase_table_2(key int, value string)
> STORED BY 'org.apache.hadoop.hive.hbase.HBaseStorageHandler'
> WITH SERDEPROPERTIES ("hbase.columns.mapping" = "cf1:val")
> TBLPROPERTIES("hbase.table.name" = "my_hbase_table");

```

Now we can run a Hive query against the pre-existing HBase table my_hbase_table that Hive sees as hbase_table_2:

```

hive> SELECT * FROM hbase_table_2 WHERE key > 400 AND key < 410;
Total MapReduce jobs = 1
Launching Job 1 out of 1
Number of reduce tasks is set to 0 since there's no reduce operator
...
OK
401      val_401
402      val_402
403      val_403
404      val_404
406      val_406
407      val_407
409      val_409
Time taken: 9.452 seconds

```

Hive and HPL/SQL Integration

Note: This feature is presented as a developer preview. Developer previews are not tested for production environments, and should be used with caution.

HPL/SQL includes a Hive UDF function that allows you to execute HPL/SQL scripts (user-defined functions written in HPL/SQL language) in Hive queries.

HPL/SQL uses the `hplsql_locals.sql` file to parse a prepared procedure that can be used in the Hive query. If you want to add and use multiple functions, you should add each function to the `hplsql_locals.sql` file.

For example, to call the `hello` function from a Hive query, you can add a `hello` function to the `hplsql_locals.sql` file:

```
CREATE FUNCTION hello(text STRING)
  RETURNS STRING
BEGIN
  RETURN 'Hello, ' || text || '!';
END;
```

There are two possible ways to run the HPL/SQL `hello` function:

Running HPL/SQL from Hive CLI/Hive Beeline

The `hplsql_locals.sql` file must be located in the directory where the Hive CLI is started or in the `/opt/mapr/hive/hive-<version>/bin` directory if you are using Beeline. After adding the `hello` function to the `hplsql_locals.sql` file, register the HPL/SQL UDF in Hive as follows:

```
CREATE TEMPORARY FUNCTION hplsql AS 'org.apache.hive.hplsql.Udf';
```

To use the `hello` function written in HPL/SQL language in Hive, use a query such as the following:

```
SELECT hplsql('hello(:1)', name) FROM users;
```

Running HPL/SQL from the HPL/SQL CLI

When you run HPL/SQL scripts using the HPL/SQL CLI, you can use user-defined functions the same way you use built-in functions:

```
hplsql -e "SELECT hello(name) FROM users;"
```

The HPL/SQL CLI automatically connects to HiveServer2 using the configuration from the `hplsql-site.xml` file, registers the Hive UDF, and modifies the function call in the SQL statements. But you must ensure that the `hplsql_locals.sql` file containing the user-defined functions is located in the `/opt/mapr/hive/hive-<version>/bin` directory, where HiveServer2 can parse it.

For more information, see [User-Defined Functions and Stored Procedures](#).

Hive and HCatalog Integration

The [HCatalog](#) on page 4933 library provides applications with a table view of the file system layer in your cluster, expanding your application's options from read/write data streams to add table operations such as `get row` and `store row`. The HCatalog library stores the metadata required for its operations in the Hive Metastore.

The `hcat` utility can execute any of the data definition language (DDL) commands available in Hive that do not involve launching a MapReduce application. Internally, the `hcat` utility passes DDL commands to the `hive` program. Data stored in the Data Fabric file system is serialized and deserialized through

InputStorageFormats and OutputStorageFormats objects for records. Fields within a record are parsed with SerDes.

WARNING:

The [hive-json-serde-0.2.jar](#) JSON serializer/deserializer has not implemented a `serialize()` method and as a result does not function.

The WebHCat server provides a REST-like web API for HCatalog. For more information about using WebHCat, see [Hive and WebHCat Integration](#) on page 5034.

This section contains the following topics:

Accessing HCatalog Tables from Hive

About this task

To access tables created in HCatalog in Hive, use the following command to append paths to your HADOOP_CLASSPATH environment variable:

```
export HADOOP_CLASSPATH=${HADOOP_CLASSPATH}:$HCAT_HOME/share/hcatalog/
storage-handlers/hbase/lib/hbase-storage-handler-<version>.jar:$HCAT_HOME/
share/hcatalog/hcatalog-core-<version>-mapr.jar:$HCAT_HOME/share/hcatalog/
hcatalog-pig-adapter-<version>-mapr.jar:$HCAT_HOME/share/hcatalog/
hcatalog-server-extensions-<version>-mapr.jar
```

Loading and Retrieving Data from Pig

About this task

To use the HCatalog library HCatLoader and HCatStorer to load and retrieve data from Pig:

Procedure

1. Create a table with the hcat utility.

```
hcat -e "create table hcatpig(key int, value string)"
```

2. Verify that the table and table definition both exist.

```
hcat -e "describe formatted hcatpig"
```

3. Load data into the table from Pig: Copy the \$HIVE_HOME/examples/files/kv1.txt file into the MapRFS file system, then start Pig and load the file with the following commands:

```
pig -useHCatalog -Dfs.default.name=maprfs://CLDB_Host:7222/
grunt> A = LOAD 'kv1.txt' using PigStorage('\u0001') AS(key:INT,
value:chararray);
grunt> STORE A INTO 'hcatpig' USING
org.apache.hive.hcatalog.pig.HCatStorer();
```

4. Retrieve data from the `hcatpig` table with the following Pig commands: Another way to verify that the data is loaded into the `hcatpig` table is by looking at the contents of `maprfs://user/hive/warehouse/hcatpig/`. HCatalog tables are also accessible from the Hive CLI. All Hive queries work on HCatalog tables.

```
B = LOAD 'default.hcatpig' USING
org.apache.hive.hcatalog.pig.HCatLoader();
dump B; // this should display the records in kv1.txt
```

Running MapReduce Applications

About this task

This example uses a sample MapReduce program named `HCatalogMRTest.java`.

Procedure

1. From the command line, issue the following commands to define the environment:

```
export LIB_JARS=
$HCAT_HOME/share/hcatalog/hcatalog-core-<version>-mapr.jar,
$HIVE_HOME/lib/hive-metastore-<version>-mapr.jar,
$HIVE_HOME/lib/libthrift-<version>.jar,
$HIVE_HOME/lib/hive-exec-<version>-mapr.jar,
$HIVE_HOME/lib/libfb303-<version>.jar,
$HIVE_HOME/lib/jdo2-api-<version>-ec.jar,
$HIVE_HOME/lib/slf4j-api-<version>.jar

export HADOOP_CLASSPATH=
$HCAT_HOME/share/hcatalog/hcatalog-core-<version>-mapr.jar:
$HIVE_HOME/lib/hive-metastore-<version>-mapr.jar:
$HIVE_HOME/lib/libthrift-<version>.jar:
$HIVE_HOME/lib/hive-exec-<version>-mapr.jar:
$HIVE_HOME/lib/libfb303-<version>.jar:
$HIVE_HOME/lib/jdo2-api-<version>-ec.jar:
$HIVE_HOME/conf:
$HADOOP_HOME/conf:
$HIVE_HOME/lib/slf4j-api-<version>.jar
```

2. Compile `HCatalogMRTest.java`:

```
javac -cp `hadoop classpath`:${HCAT_HOME}/share/hcatalog/
hcatalog-core-<version>-mapr.jar HCatalogMRTest.java -d .
```

3. Create a JAR file:

```
jar -cf hcatmrtest.jar org
```

4. Create an output table:

```
hcat -e "create table hcatpigoutput(key int, value int)"
```

5. Run the job: At the end of the job, the file `hcatpigoutput` should have entries in the form `key, count`.

```
hadoop --config $HADOOP_HOME/conf jar ./hcatmrtest.jar
org.myorg.HCatalogMRTest -libjars $LIB_JARS hcatpig hcatpigoutput
```

Running Non-MapReduce Applications

About this task

This example uses a sample MapReduce program named `TestReaderWriter.java`.

Procedure

1. Add the following JAR files to your `$HADOOP_CLASSPATH` environment variable with the following command:

```
export HADOOP_CLASSPATH=$HADOOP_CLASSPATH:/opt/mapr/hive/
hive-<version>/lib/antlr-runtime-3.4.jar:/opt/mapr/hive/
hive-<version>/lib/hive-cli-<version>-mapr.jar
```

2. Compile the test program with the following command:

```
javac -cp `hadoop classpath`:${HCAT_HOME}/share/hcatalog/
hcatalog-core-<version>-mapr.jar TestReaderWriter.java -d <directory>
```

3. Create a JAR file with the following command:

```
jar -cf hcatrwtest.jar org
```

4. Run the job with the following command:

```
hadoop jar /root/<username>/hcatalog/hcatrwtest.jar
org.apache.hive.catalog.data.TestReaderWriter -libjars $LIB_JARS
```

Results

The last command should result in a table named `mytbl` that is populated with data.

Hive and WebHCat Integration

The WebHCat server provides a REST-like web API for HCatalog. Applications make HTTP requests to run Pig, Hive, and HCatalog DDL from within applications.

This topic contains the following sections:

Configuring the WebHCat Server

About this task

The properties to configure WebHCat are in the following file:

```
/opt/mapr/hive/hive-<version>/hcatalog/etc/webhcat/webhcat-site.xml
```

When you set up WebHCat, you can configure file system and Zookeeper as storage.

Procedure

1. To configure storage for WebHCat, add the MapRFS location property.

```
<property> <name>templeton.storage.class</name>
<value>org.apache.hive.hcatalog.templeton.tool.HDFSStorage</value> </
property> <property> <name>templeton.storage.root</name> <value>/user/
mapr/webhcat</value> <description>The path to the directory to use for
storage</description> </property>
```

2. To configure WebHCat for Pig:

- a) Compress the Pig installation, then move the compressed file to the MapRFS layer.

```
# cd /opt/mapr/pig
# tar -czvf /tmp/pig-<version>.tar.gz pig-<version>/
# hadoop fs -mkdir /user/mapr/webhcat
# hadoop fs -put /tmp/pig-<version>.tar.gz /user/mapr/webhcat/
```

- b) Set the value of the `templeton.pig.archive` property to the location of the compressed file.

```
<property> <name>templeton.pig.archive</name> <value>maprfs:///user/
mapr/webhcat/pig-<version>.tar.gz</value> </property>
```

- c) Set the value of the `templeton.pig.path` property to the path inside the compressed Pig file where the Pig binary is located.

```
<property>
  <name>templeton.pig.path</name>
  <value>pig-<version>.tar.gz/pig-<version>/bin/pig</value>
</property>
```

3. To configure WebHCat for Hive:

- a) Compress the Hive installation, then move the compressed file to the file system layer.

```
# cd /opt/mapr/hive
# tar -czvf /tmp/hive-<version>.tar.gz hive-<version>/
# hadoop fs -mkdir /user/mapr/webhcat
# hadoop fs -put /tmp/hive-<version>.tar.gz /user/mapr/webhcat
```

- b) Set the value of the `templeton.hive.archive` property to the location of the compressed file.

```
<property> <name>templeton.hive.archive</name> <value>maprfs:///user/
mapr/webhcat/hive-<version>.tar.gz</value> </property>
```

- c) Set the value of the `templeton.hive.path` property to the path inside the compressed Hive file where the Hive binary is located.

```
<property>
  <name>templeton.hive.path</name>
  <value>hive-<version>.tar.gz/hive-<version>/bin/hive</value>
</property>
```

4. To Configure WebHCat for streaming:

- a) Copy the Streaming JAR to the file system layer.

```
# hadoop fs -put
/opt/mapr/hadoop/hadoop-<version>/contrib/streaming/
hadoop-<version>-dev-streaming.jar /user/mapr/webhcat
```

- b) Set the templeton.streaming.jar property to the location of the streaming JAR.

```
<property> <name>templeton.streaming.jar</name> <value>maprfs:///user/
mapr/webhcat/hadoop-<version>-dev-streaming.jar</value> </property>
```

Configure WebHCat Server to use SSL Encryption

About this task

You can configure WebHCat REST-API to use SSL (Secure Sockets Layer) encryption. The following WebHCat properties are added to enable SSL:

```
templeton.use.ssl
Default value: false
Description: Set this to true for using SSL encryption for WebHCat server

templeton.keystore.path
Default value: <empty string>
Description: SSL certificate keystore location for WebHCat server

templeton.keystore.password
Default value: <empty string>
Description: SSL certificate keystore password for WebHCat server

templeton.ssl.protocol.blacklist
Default value: SSLv2,SSLv3
Description: SSL Versions to disable for WebHCat server

templeton.host
Default value: 0.0.0.0
Description: The host address the WebHCat server will listen on
```

Modifying the webhcat-site.xml file:

Procedure

Configure the following properties in the webhcat-site.xml file to enable SSL encryption on each node where HWebHCat is installed:

```
<!-- WebHCat SSL -->
<property>
  <name>templeton.use.ssl</name>
  <value>true</value>
</property>

<property>
  <name>templeton.keystore.path</name>
  <value>/opt/mapr/conf/ssl_keystore</value>
</property>

<property>
  <name>templeton.keystore.password</name>
```

```
<value><ssl-keystore-password></value>
</property>
```

NOTE: After running `/opt/mapr/server/configure.sh -R`, all properties needed to enable SSL encryption for WebHCat are added automatically to `webhcat-site.xml` on the MapR-SASL secure cluster.

To check status of WebHCat server configured for SSL encryption, use following command:

```
curl -k 'https://<user>:<password>@<host>:50111/templeton/v1/status'
```

Requirements for Using Automatically Generated PEM Files

To use automatically generated PEM files for the WebHCat REST API on a MapR-SASL cluster, you need to have a cluster with a host name that consists at least of three parts: administrator user name and password, and WebHCat REST API host.

About this task

Check the status of the WebHCat REST API to make sure you have a cluster with a host name that consists of the administrator user name and password, and WebHCat REST API host service:

```
curl --cacert /opt/mapr/conf/ssl_truststore.pem -u
<cluster_admin_user>:<cluster_admin_password>
"https://<myhost.mapr.com>:50111/templeton/v1/status" -v
```

Results

The sample output for this example is as follows:

```
* TCP_NODELAY set
* Connected to c74v610.mapr.com (192.168.122.254) port 50111 (#0)
* Cipher selection: ALL:!EXPORT:!EXPORT40:!EXPORT56:!aNULL:!LOW:!
RC4:@STRENGTH
* successfully set certificate verify locations:
CAfile: /opt/mapr/conf/ssl_truststore.pem
CApath: none
* (303) (OUT), TLS Unknown, Certificate Status (22):
* (303) (OUT), TLS handshake, Client hello (1):
* (303) (IN), TLS handshake, Server hello (2):
* (303) (IN), TLS handshake, Certificate (11):
* (303) (IN), TLS handshake, Server key exchange (12):
* (303) (IN), TLS handshake, Server finished (14):
* (303) (OUT), TLS handshake, Client key exchange (16):
* (303) (OUT), TLS change cipher, Client hello (1):
* (303) (OUT), TLS handshake, Finished (20):
* (303) (IN), TLS change cipher, Client hello (1):
* (303) (IN), TLS handshake, Finished (20):
* SSL connection using unknown / ECDHE-RSA-AES256-GCM-SHA384
* Server certificate:
*  subject: CN=*.mapr.com
*  start date: May 10 15:18:03 2018 GMT
*  expire date: Apr 16 15:18:03 2118 GMT
*  common name: *.mapr.com (matched)
*  issuer: CN=*.mapr.com
*  SSL certificate verify ok.
* Server auth using Basic with user 'mapr'
> GET /templeton/v1/status HTTP/1.1
> Host: c74v610.mapr.com:50111
> Authorization: Basic bWFwcjptYXBY
> User-Agent: curl/7.59.0
```

```
> Accept: */*
>
< HTTP/1.1 200 OK

* Connection #0 to host c74v610.mapr.com left intact
{"version":"v1","status":"ok"}
```

Managing the WebHCat Server

About this task

As of Hive 0.13-1504 and Hive 1.0-1504, WebHCat is managed by Warden. Therefore, you can start and stop WebHCat using maprccli and the Control System.

Starting the WebHCat Server

About this task

Applies to versions prior to Hive 0.13-1504 and Hive 1.0-1504:

```
# ./webhcat_server.sh start
```

Starting WebHCat Using the maprccli

Procedure

1. Make a list of nodes on which Hive Metastore is configured.
2. Issue the maprccli node services command:

```
maprccli node services -name hcat -action start -nodes <space delimited
list of nodes>
```

Stopping WebHCat Using the maprccli

Procedure

1. Make a list of nodes on which Hive Metastore is configured.
2. Issue the maprccli node services command:

```
maprccli node services -name hcat -action stop -nodes <space delimited
list of nodes>
```

Starting or Stopping WebHCat Using the Control System

Procedure

1. In the Navigation pane, expand the Cluster Views pane and click **Dashboard**.
2. In the Services pane, click **WebHcat** to open the Nodes screen displaying all the nodes on which Hive Metastore is configured.

3. On the Nodes screen, click the hostname of each node to display its Node Properties screen.
4. On each Node Properties screen, use the **Stop/Start** button in the WebHcat row under Manage Node Services to start WebHcat.

Checking the Error Logs

About this task

Go to the following folder:

```
/opt/mapr/hive/hive-<version>/logs/<user.name>/webhcat
```

NOTE: If you are running a Hive 0.13 version prior Hive 0.13-1504, go to the /tmp/<user.name>/webhcat folder to view the error logs.

Verifying the Server's Status

About this task

In a web browser, navigate to:

```
http://hostname:50111/templeton/v1/status?user.name=root
```

A healthy server will return the string {"status": "ok", "version": "v1"}. You can change the port number from the default value of 50111 by editing the webhcat-site.xml file.

Running Jobs on the WebHCat Server

About this task

REST Calls in WebHCat

The base URI for REST calls in WebHCat is `http://<host>:<port>/templeton/v1/`. The following table lists elements appended to the base URI and DDL commands.

URI	Description
Server Information	
/status	Shows WebHCat server status.
/version	Shows WebHCat server version.
DDL Commands	
/ddl/database	List existing databases.
/ddl/database/<mydatabase>	Shows properties for the database named <i>mydatabase</i> .
/ddl/database/<mydatabase>/table	Shows tables in the database named <i>mydatabase</i> .
/ddl/database/<mydatabase>/table/<mytable>	Shows the table definition for the table named <i>mytable</i> in the database named <i>mydatabase</i> .
/ddl/database/<mydatabase>/table/<mytable>/property	Shows the table properties for the table named <i>mytable</i> in the database named <i>mydatabase</i> .

Launching a MapReduce Job with WebHCat

About this task

WebHCat launches two jobs for each MapReduce job. The first job, `TempletonControllerJob`, has one map task. The map task launches the actual job from the REST API call. Check the status of both jobs and the output directory contents.

Procedure

1. Copy the MapReduce example job to the MapRFS layer:

```
hadoop fs -put /opt/mapr/hadoop/hadoop-<version>/
hadoop-<version>-dev-examples.jar /user/mapr/webhcat/examples.jar
```

2. Use the `curl` utility to launch the job:

```
curl -s -d jar=examples.jar -d class="terasort" -d arg=teragen.test -d
arg=whop3 'http://localhost:50111/templeton/v1/mapreduce/jar?
user.name=<username>'
```

Launching a Streaming MapReduce Job with WebHCat

Procedure

1. Use the `curl` utility to launch the job:

```
curl -s -d arg=teragen.test -d output=mycounts -d mapper=/bin/cat -d
reducer="/usr/bin/wc -w" 'http://localhost:50111/templeton/v1/mapreduce/
streaming?user.name=<username>'
```

2. Check the job status for both WebHCat jobs at the jobtracker page in the Control System.

Launching a Pig Job with WebHCat

Procedure

1. Copy a data file into MapRFS:

```
hadoop fs -put $HIVE_HOME/examples/files/kv1.txt /user/<user name>/
```

2. Create a `test.pig` file with the following contents:

```
A = LOAD 'kv1.txt' using PigStorage('\u0001') AS(key:INT,
value:chararray);
STORE A INTO 'pig.output';
```

3. Copy the `test.pig` file into MapR filesystem:

```
hadoop fs -put test.pig /user/<user name>/
```

4. Run the Pig REST API command:

```
curl -s -d file=test1.pig -d arg=-v 'http://localhost:50111/templeton/v1/
pig?user.name=<username>'
```

5. Monitor the contents of the `pig.output` directory.

6. Check the JobTracker page for two jobs: `TempletonControllerJob` and `PigLatin`.

Launching a Hive Job with WebHCat

Procedure

1. Create a table:

```
curl -s -d execute="create+external+table+ext3(t+TIMESTAMP)+location /
user/<user name>/ext3" 'http://localhost:50111/templeton/v1/hive?
user.name=<username>'
```

2. Load data into the table:

```
curl -s -d execute="insert+overwrite+table+ext3+select+*+from+datetable"
'http://localhost:50111/templeton/v1/hive?user.name=<username>'
```

3. List the tables:

```
curl -s -d execute="show+tables" -d statusdir='hive.output' 'http://
localhost:50111/templeton/v1/hive?user.name=<username>'
```

The list of tables is in `hive.output/stdout`.

The Job Queue

About this task

To show HCatalog jobs for a particular user, navigate to the following address:

```
http://<hostname>:<port>/templeton/v1/queue/?user.name=<username>
```

The default port for HCatalog is 50111.

Hive and Tez Integration

You can use Tez, instead of MapReduce, for generic data processing tasks. Tez significantly increases the processing speed. Tez, working with Hive, provides lower latency for interactive queries and higher throughput for batch queries.

Configuring Hive and Tez

About this task

To configure Hive on Tez, repeat the following steps on each node where you want to configure Hive on Tez. Tez mode for MR jobs is not compatible with all MR jobs, so do not set up the whole cluster to work on Tez.

There is a known issue related to the incomplete removal of previously installed Tez packages. The issue affects platforms on which Tez was installed but later removed using `sudo apt-get remove mapr-tez`. Because of Ubuntu-specific behavior and Tez source-code issues, the `remove` command removes Tez only partially in some installations. If this happens, an error is generated when you try to re-install Tez on Ubuntu, as described following in step 1. If you believe your installation might have this issue, you can prevent the error. Before performing the following steps, use the `purge` command to completely remove all previously installed Tez packages.

Procedure

1. Install Tez if it is already not installed. To install Tez, run the following command:

On CentOS / RedHat	yum install mapr-tez
On SLES	zypper install mapr-tez
On Ubuntu	apt-get install mapr-tez

NOTE: Repeat this step on each node where you want Hive on Tez to be configured.

2. Create the /apps/tez directory on Data Fabric file system.

To create, run the following commands:

```
hadoop fs -mkdir /apps
hadoop fs -mkdir /apps/tez
```

3. Upload the Tez libraries to the /tez directory on the Data Fabric file system.

To upload, run the following commands:

```
hadoop fs -put /opt/mapr/tez/tez-<version> /apps/tez
hadoop fs -chmod -R 755 /apps/tez
```

4. Verify the upload.

To verify, run the following command:

```
hadoop fs -ls /apps/tez/tez-<version>
```

5. Set the Tez environment variables. To set, open the /opt/mapr/hive/hive-<version>/conf/hive-env.sh file, add the following lines, and save the file:

```
export TEZ_CONF_DIR=/opt/mapr/tez/tez-<version>/conf
export TEZ_JARS=/opt/mapr/tez/tez-<version>/*:/opt/mapr/tez/
tez-<version>/lib/*
export HADOOP_CLASSPATH=$TEZ_CONF_DIR:$TEZ_JARS:$HADOOP_CLASSPATH
```

NOTE: Repeat this step on each node where you want Hive on Tez to be configured.

6. Configure Hive for Tez engine. To configure, open the `/opt/mapr/hive/hive-<version>/conf/hive-site.xml` file, add the following lines, and save the file.

```
<property>
  <name>hive.execution.engine</name>
  <value>tez</value>
</property>
```

Add the `hive.exec.pre.hooks`, `hive.exec.post.hooks`, and `hive.exec.failure.hooks` properties with value `org.apache.hadoop.hive.ql.hooks.ATSHook` to use the Hive queries page in the Tez UI.

NOTE: Starting from EEP 7.1.0, the following execution-hooks properties are managed by running `configure.sh` command with `-R` option.

```
<property>
  <name>hive.exec.pre.hooks</name>
  <value>org.apache.hadoop.hive.ql.hooks.ATSHook</value>
</property>

<property>
  <name>hive.exec.post.hooks</name>
  <value>org.apache.hadoop.hive.ql.hooks.ATSHook</value>
</property>

<property>
  <name>hive.exec.failure.hooks</name>
  <value>org.apache.hadoop.hive.ql.hooks.ATSHook</value>
</property>
```

NOTE: Repeat this step on each node where you want Hive on Tez to be configured.

7. Run `configure.sh` with the `-R` option.

```
/opt/mapr/server/configure.sh -R
```

NOTE: Starting in EEP 6.0.1 and later, Tez should be configured by running the `$MAPR_HOME/server/configure.sh` script with the `-R` option.

8. Configure Tez shuffle on a secured cluster:
Refer to [Tez Shuffle](#) on page 5051 to configure SSL encryption on shuffle.

Known Issues and Restrictions

Sqoop importing data into Hive fails when the entire cluster is configured to use Tez.

This is because of Sqoop's incompatibility with Tez.

Workaround: Do not configure the entire cluster to use Tez.

Percentage sampling is not supported in `org.apache.hadoop.hive.ql.io.HiveInputFormat`.

Hive uses `org.apache.hadoop.hive.ql.io.HiveInputFormat` by default and so queries like `'SELECT * FROM tablename TABLESAMPLE(20 percent);'` will not work for Hive on Tez.

Workaround: Instead of `org.apache.hadoop.hive.ql.io.HiveInputFormat`, use

`org.apache.hadoop.hive ql.io.CombineHiveInputFormat.`

To change input format, do one of the following:

- Set `hive.tez.input.format` in hive shell. For example:

```
hive> set
hive.tez.input.format=org.apache.ha
doop.hive.ql.io.CombineHiveInputFor
mat;
```

- Add `org.apache.hadoop.hive.ql.io.CombineHiveInputFormat` to `hive-site.xml` file. For example:

```
<property>
  <name>hive.tez.input.format</
name>

  <value>org.apache.hadoop.hive.ql.io
.CombineHiveInputFormat</value>
</property>
```

Hive on Tez does not work well with Sequence Files Schema changes

TEZ-2741

Limitations with common joins

HIVE-11693: The `CommonMergeJoinOperator` only sets big table position when it has inputs for big table. If the input is empty, the method is not called.

HiveServer2 on Tez doesn't support concurrent queries within one session

HIVE-9223: When multiple queries are submitted in the same HS2 session concurrently, some queries fail with an error.

Tez upgrade issues

- No support for preserving configuration from EEP-5.0.0 and EEP-4.1.1 (ECO-1803) to EEP-6.0.0(1808) or EEP-5.0.1(1808) on Ubuntu.
- No support for preserving Tomcat configuration from previous EEPs to EEP-6.0.0 (1808).
- You should manually stop the Tomcat service and delete the tomcat folder as a precondition if you are updating or upgrading Tez from the following EEPs:
EEP-4.0.0
EEP-4.1.0

Tez shuffle SSL encryption issue

During a shuffle phase, the `javax.net.ssl.SSLException` error could occur on a multi-node cluster due to insufficient Tez shuffle SSL encryption configuration, see [Tez Shuffle](#) on page 5051 for a solution.

SQL Limitations

The following is a list of SQL limitations on Hive on Tez:

Issue	Summary
HIVE-11693	<code>CommonMergeJoinOperator</code> throws exception with Tez.

Issue	Summary
HIVE-9989	Hive on Tez group by with cast(NULL AS BIGINT) throws NPE.
HIVE-11270	Tez gives different responses when run on Physical tables and logical views.
HIVE-9223	HiveServer2 on Tez doesn't support concurrent queries within one session.
HIVE-13623	Hive on Tez produces wrong results when withClause and (outer) joins.
TEZ-2741	Hive on Tez does not work well with Sequence Files Schema changes.
HIVE-13926	Cannot limit reduce (not both Map and Reduce) memory in Tez engine.

Hive-on-Tez User Interface

This section describes how to install, configure, manage, and start the Hive-on-Tez user interface.

NOTE: ATSV2 is incompatible with the Tez UI. ATSV2 should not be installed across the cluster nodes if you are enabling the Tez UI by configuring ATSV1 or ATSV1.5.

WARNING: The Hive-on-Tez user interface supports RM HA only starting from the 1803 release (EEP 4.1.1 and EEP-5.0.0).

Installing the Hive-on-Tez User Interface

This topic describes installation of the Hive-on-Tez user interface by using the Data Fabric Installer or manual steps.

Installation Using the Data Fabric Installer

When you use the Data Fabric Installer to install Tez, the timeline server for the Hive-on-Tez user interface is installed automatically. If the **Enable MapR Secure Cluster** option is enabled in the Data Fabric Installer, the timeline server is installed to be secure.

The Tomcat server is installed into this folder:

```
/opt/mapr/tez/tez-<version>/tomcat/apache-tomcat-<version>
```

To start using the Hive-on-Tez user interface if the **Enable MapR Secure Cluster** option is enabled or if the cluster is Kerberized, you must log in to the timeline server user interface:

```
https://<hostname>:8190
```

Manual Installation

To install the Hive-on-Tez user interface manually:

1. Install and configure mapr - tez as described in [Configuring Hive and Tez](#) on page 5041.

2. Install the timeline server:

On CentOS / Red Hat	yum install mapr-timelineserver
On SLES	zypper install mapr-timelineserver
On Ubuntu	apt-get install mapr-timelineserver

NOTE: Install the timeline server on a single node. The Hive-on-Tez user interface does not support High Availability (HA).

Configuring the Timeline Server to Use the Hive-on-Tez User Interface

This topic describes how to configure the timeline server to use the Hive-on-Tez user interface. This topic includes security configuration information.

About this task

When the timeline server is installed using the MapR Installer, the installer secures the timeline server automatically. When you install the timeline server manually, use these steps.

NOTE: This procedure assumes that you have previously configured the cluster using the `configure.sh` script.

Procedure

1. Run `configure.sh -R` (on all Hive nodes), replacing `<hostname>` with the name of your timeline server node:

```
sudo /opt/mapr/server/configure.sh -R -TL <hostname>
```

NOTE: Make sure the hostname matches the CN in `ssl_keystore` for secure clusters. If not, all hive and yarn jobs fail. The hostname can be obtained using the `$hostname -f` command.

Running `configure.sh -R` configures the timeline server properties in `/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/yarn-site.xml` for enhanced security.

2. To use the timeline server with Kerberos, you need to make additional entries to the `/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/yarn-site.xml` file. Replace the following variables with real values:

- MAPR_PRINCIPAL
- PATH_TO_KEYTAB
- HTTP_PRINCIPAL

```
<property>
  <name>yarn.timeline-service.principal</name>
  <value>MAPR_PRINCIPAL</value>
</property>
<property>
  <name>yarn.timeline-service.keytab</name>
  <value>PATH_TO_KEYTAB</value>
</property>
<property>
  <name>yarn.timeline-service.http-authentication.kerberos.principal</
name>
  <value>HTTP_PRINCIPAL</value>
</property>
```

```
<property>
  <name>yarn.timeline-service.http-authentication.kerberos.keytab</name>
  <value>PATH_TO_KEYTAB</value>
</property>
```

3. Restart the resource manager:

```
maprcli node services -name resourcemanager -action restart -nodes
<hostname>
```

Configuring the Tomcat Server

This topic describes how to configure and manage the Tomcat server for the Hive-on-Tez user interface.

Extracting the Tomcat Server

You can only extract the Tomcat server after you manually install Tez. Tez has a built-in Tomcat Server archive with the latest version. You can find the archive at:

```
$TEZ_HOME/tomcat/tomcat.tar.gz
```

To extract the Tomcat server, use these commands in the command line:

```
cd $TEZ_HOME/tomcat/
sudo tar -zxvf tomcat.tar.gz -C $TEZ_HOME/tomcat
```

Change the permissions for the /tomcat directory to the user who will be running the Tomcat server:

```
sudo chown -R <$USER>:<$USER_GROUP> $TEZ_HOME/tomcat
```

Configuring the Timeline Server Base URL and Resource Manager WEB URL

To set the timelineBaseUrl and RMwebUrl, update the Tez configuration file.

The file location is:

```
$TEZ_HOME/tomcat/apache-tomcat-<version>/webapps/tez-ui/config/configs.js
```

To configure the Timeline Server Base URL and Resource Manager WEB URL:

1. Replace TIME_LINE_BASE_URL with the real URL. For example:

- For a non-secure configuration:

```
'http://localhost:8188'
```

- For a secure configuration:

```
'https://localhost:8190'
```

2. Replace RM_WEB_URL with the real URL. For example:

- For a non-secure configuration:

```
'http://localhost:8088'
```

- For a secure configuration:

```
'https://localhost:8090'
```

- For a proxy server, specify the user-defined URL in the `yarn-site.xml` file, as shown:

```
<property>
  <name>yarn.web-proxy.address</name>
  <value><hostname>:<port></value>
</property>
```

Replace `RM_WEB_URL` with the value specified as the `yarn.web-proxy.address` property.

Configuring SSL for the Tomcat Server on a Secure Cluster

To start the Tomcat server with the exposed SSL port, edit the following properties in the `$TEZ_HOME/tomcat/apache-tomcat-<version>/conf/server.xml` file, replacing `<ssl-keystore-password>` with the real SSL keystore password.

- Find the default configuration of the exposed port:

```
<Connector port="9383"
  protocol="HTTP/1.1"
  connectionTimeout="20000"
  redirectPort="8443" />
```

- Change the configuration for SSL:

```
<Connector port="9393"
  SSLEnabled="true"
  maxThreads="150"
  scheme="https"
  secure="true"
  clientAuth="false"
  sslProtocol="TLS"
  keystoreFile="/opt/mapr/conf/ssl_keystore"
  keystorePass="<ssl-keystore-password>" />
```

NOTE: If you used Installer version 1.15.0.0 to install the cluster, see [Hive-on-Tez User Interface Known Issues](#) on page 5050.

Starting and Stopping the Tomcat Server

To start the Tomcat server, run this script:

```
$TEZ_HOME/tomcat/apache-tomcat-<version>/bin/startup.sh
```

To stop the Tomcat server, run this script:

```
$TEZ_HOME/tomcat/apache-tomcat-<version>/bin/shutdown.sh
```

NOTE: The `timelineBaseUrl` maps to the YARN Timeline Server, and the `RMwebUrl` maps to the YARN Resource Manager. For default port information, see [Ports Used by HPE Data Fabric Software](#) on page 3469.

Configuring the Tez UI (Tomcat) to be Managed by Warden

This section describes how to use manual steps to configure and verify that the Tez UI (Apache Tomcat) is managed by Warden.

Using the Installer to install Tez configures the Tez UI to be managed by *Warden* by default.

Prerequisites

Before continuing, ensure that the following prerequisites are met:

- Hive and Tez are installed on the node.
- You have completed all of the tasks described under [Hive-on-Tez User Interface](#) on page 5045.
- The Tez UI is up and running and functioning properly.

Manually Configure the Tez UI Server

To manually configure the Tez UI server so that it can be managed by Warden and the Control System, copy and rename the `warden.tezui.conf.template` file in the Tez conf dir:

```
mv /opt/mapr/tez/tez-<version>/conf/warden.tezui.conf.template /opt/mapr/
conf/conf.d/warden.tezui.conf
```

Verify that the Tez UI Is Managed by Warden

After configuration, to verify that the Tez UI is managed by Warden, you can try using the Tez UI directly, or use the command line to check the list of open files (specify port 9383 or 9393):

```
lsof -i:<port>
```

The following example shows that the Tomcat service is running:

```
lsof -i:9383
COMMAND  PID USER  FD  TYPE DEVICE SIZE/OFF NODE NAME
java     31580 mapr   56u  IPv6 271941      0t0  TCP *:9383 (LISTEN)
```

Use maprccli Commands to Stop, Start, or Restart the Tez UI

The following `maprccli` commands help you manage the Tomcat server. Use these commands to confirm that you can manage the Tez UI through the `maprccli`. You can also use these commands to stop, start, or restart the Tomcat server after configuration changes.

To stop node services for the Tez UI:

```
/opt/mapr/bin/maprccli node services -name tezui -action stop -nodes
<tez_ui_node_name>
```

To start node services for the Tez UI:

```
/opt/mapr/bin/maprccli node services -name tezui -action start -nodes
<tez_ui_node_name>
```

To restart node services for the Tez UI:

```
/opt/mapr/bin/maprccli node services -name tezui -action restart -nodes
<tez_ui_node_name>
```

Use the Control System Commands to Stop, Start, or Restart the Tez UI

In the Control System, the procedure is generally the same for stopping, starting, and restarting the Tez UI:

1. Log in to the Control System and click **Services** to display the list of services on the cluster.
2. Click one of the following icons for the Tez UI service:
 - To stop the service, click .
 - To start the service, click .
 - To restart the service, click .

Integrating the Hive-on-Tez User Interface with Tez

This topic describes how to integrate the Hive-on-Tez user interface with Tez.

1. Add the following entry to the `/opt/mapr/tez/tez-<version>/conf/tez-site.xml` file, replacing `<hostname>:<port>` with the real host name. You can use 9383 or 9393 for the port. 9383 is HTTP and 9393 is HTTPS Tomcat port for the Hive-on-Tez user interface.

```
<property>
  <description>Enable Tez to use the Timeline Server for History
  Logging</description>
  <name>tez.history.logging.service.class</name>

  <value>org.apache.tez.dag.history.logging.ats.ATSHistoryLoggingService</
  value>
</property>

<property>
  <description>URL for where the Tez UI is hosted</description>
  <name>tez.tez-ui.history-url.base</name>
  <value>http(s)://<hostname>:<port>/tez-ui/</value>
</property>
```

Repeat this step on each node where you want the Hive-on-Tez user interface to be configured.

Connecting to the Hive-on-Tez User Interface

This topic describes how to connect to the Hive-on-Tez user interface.

To start using the Hive-on-Tez user interface on a Data Fabric secure or Kerberized cluster, you must log in to the timeline server user interface and RM UI:

```
https://<hostname>:8190
```

```
https://<hostname>:8090
```

To connect to the Hive-on-Tez user interface on secure clusters, use a browser to navigate to:

```
https://<hostname>:9393/tez-ui/
```

where `<hostname>` is the host where the Tomcat server is running.

Hive-on-Tez User Interface Known Issues

This topic describes known issues that you should be aware of while troubleshooting.

Installer Configuration Known Issues

If you used Installer version 1.15.0.0 to install the cluster, re-assign the following existing truststore SSL variables with the correct keystore SSL variables:

Existing variables (truststore)	Correct variables (keystore)
keystoreFile="/opt/mapr/conf/ssl_truststore"	keystoreFile="/opt/mapr/conf/ssl_keystore"
keystorePass="<ssl-truststore-password>"/>	keystorePass="<ssl-keystore-password>"/>

Timeline Server Known Issues

(Issue 29538) After an incremental install or rolling upgrade to MapR 6.1, the timeline server does not start. To resolve this issue, add the following entry to /opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/yarn-env.sh:

```
export YARN_TIMELINESERVER_OPTS="${YARN_TIMELINESERVER_OPTS} $
{MAPR_LOGIN_OPTS}"
```

To grant administrative privileges to any user(s), modify yarn-site.xml, as shown:

```
<property>
  <name>yarn.admin.acl</name>
  <value><user_name></value>
</property>
```

After the yarn.admin.acl property takes effect, the user specified by <user_name> has administrative privileges and access to all jobs.

For example, User-A can access all the jobs owned by User-A, by default. If User-A needs access to jobs owned by other users, administrative privileges can be granted to User-A through the yarn.admin.acl property.

Timeline server (ATS) is out of reach issue

If you get an issue similar to the following example with Tez UI and TLS UI communication (especially on Chrome browser):

```
Adapter operation failed » Timeline server (ATS) is out of reach. Either
it's down, or CORS is not enabled.
```

Consider configuring Tez UI to HTTPS instead of HTTPS. For details, see [Configuring the Tomcat Server](#) on page 5047.

Tez Shuffle

Tez uses org.apache.hadoop.mapred.ShuffleHandler provided by MapReduce version 2.0 (MRv2) as an auxiliary service, which you can choose to configure via the /opt/mapr/hadoop/hadoop-<version>/etc/hadoop/mapred-site.xml file.

On a secured cluster, Tez shuffle, SSL encryption configuration is enabled in /opt/mapr/tez/tez-<version>/conf/tez-site.xml by default:

tez.runtime.shuffle.ssl.enable	true
tez.runtime.shuffle.keep-alive.enabled	true

Also, you must configure Tez shuffle for YARN by adding the following property to the `mapred-site.xml` file. Edit the `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/mapred-site.xml` file:

<code>mapreduce.shuffle.ssl.enabled</code>	<code>true</code>
--	-------------------

Queue Management with Hive-on-Tez

HiveServer2 provides built-in functionality to set-up and handle a pool of Tez sessions in default queues. Tez initiates a session and keeps it alive to run sequential queries. Queries can be submitted through HiveServer2 clients, such as Beeline and the Hive CLI. You can manage queues through properties in `hive-site.xml`.

Queue management is strongly connected to the type of YARN Scheduler used. By default, an HPE Data Fabric cluster uses Fair Scheduler and Hive-on-Tez to run queries in queues with a user name. If a query is submitted from the Hive CLI, the real user name is used. If a query is submitted from a HiveServer2 client, such as Beeline, the queue name depends on the HiveServer2 impersonation configuration property, `hive.server2.enable.doAs`, where the queue name could be the real user name or the user name of the Hiveserver2 process.

With Capacity Scheduler, Hive queries submitted from the CLI and Beeline are configured through the `capacity-scheduler.xml` file. Default queue names are chosen from the scheduler settings, but you can also use the `tez.queue.name=<queue_name>` property to run queries in a specific queue.

Application Masters (AM) are strongly bound to YARN. You cannot change the queue for an AM that is already started. If impersonation is enabled for HiveServer2, a new AM starts next to an existing AM for a default queue. Do not use or close a default queue at the end of a lifetime.

NOTE: HiveServer2 works with or without impersonation. Impersonation is set through the `hive.server2.enable.doAs` property.

Run Queries in a Specific Queue

If you want all queries to run in a specific queue, you can configure a queue name through the `tez.queue.name` property. When you configure a queue name through the `tez.queue.name` property, Tez sets the queue name for all jobs submitted from the client to the configured `tez.queue.name`. You can set this property before each query through the Hive SET command, as shown:

```
set tez.queue.name=<queue_name>;
```

Or, you can set the property in the `hive-site.xml` file, as shown:

```
<property>
  <name>tez.queue.name</name>
  <value>my_queue</value>
</property>
```

IMPORTANT: If you set `tez.queue.name` in `hive-site.xml`, and you want the queue name to persist across all queries in the session, you must also set the `hive.server2.tez.unset.tez.queue.name` property in `hive-site.xml` to `false`, as shown:

```
<property>
  <name>tez.queue.name</name>
  <value>my_queue</value>
</property>
<property>
  <name>hive.server2.tez.unset.tez.queue.name</name>
  <value>false</value>
</property>
```

If `hive.server2.tez.unset.tez.queue.name` is set to `true`, Hive will not persist the `tez.queue.name` across queries and instead uses the default cluster queue names.

Configuration Properties

HiveServer2 has several settings related to queue management. Specify the following properties in the `hive-site.xml` file:

Property	Description	Default Value
<code>tez.queue.name</code>	The queue name for all jobs submitted from a given client. Set through the Hive CLI via the SET command before running a query or through <code>hive-site.xml</code> . If you set the property through <code>hive-site.xml</code> , and you want the setting to persist across all queries that run, set <code>hive.server2.tez.unset.tez.queue.name</code> to <code>false</code> .	No default. Must be explicitly set.
<code>hive.server2.tez.initialize.default.sessions</code>	When set to <code>true</code> , enables you to use HiveServer2 without turning on Tez for HiveServer2. Useful when you want to run queries over Tez without the pool of sessions.	<code>false</code>
<code>hive.server2.tez.default.queues</code>	A list of comma-separated values that correspond to YARN queues of the same name. When HiveServer2 is launched in Tez mode, this configuration must be set to enable multiple Tez sessions to run in parallel on the cluster.	empty string
<code>hive.server2.tez.sessions.per.default.queue</code>	A positive integer that determines the number of Tez sessions that should launch in each of the queues specified by <code>hive.server2.tez.default.queues</code> . Determines the parallelism on each queue. For example, if you specify two default queues and two sessions per default queue, four application masters start.	1
<code>hive.server2.tez.session.lifetime</code>	Defines the lifetime of the Tez sessions launched by HiveServer2 when default sessions are enabled. Set to 0 to disable session expiration.	162h
<code>hive.server2.tez.unset.tez.queue.name</code>	Controls whether the <code>tez.queue.name</code> persists across all queries in a session. Must be set to <code>false</code> for the <code>tez.queue.name</code> to persist. When set to <code>true</code> , the <code>tez.queue.name</code> only applies to the first query that runs; thereafter, the default cluster queue names are used.  NOTE: This functionality was introduced in EEP 7.01 and EEP 6.3.2. A patch for previous EEP versions is available. See Applying a Patch .	<code>true</code>

Managing Hive Services

This section includes the following topics:

Starting Hive

You can start the Hive shell from `HIVE_HOME/bin/` with the `hive` command. Example:

```
/opt/mapr/hive/hive-<version>/bin/hive
```

When the Hive shell starts, it reads an initialization file called `.hiverc` which is located in the `HIVE_HOME/bin/` or `$HOME/` directories. You can edit this file to set custom parameters or commands that initialize the Hive command-line environment, one command per line.

When you run the Hive shell, you can specify a MySQL initialization script file using the `-i` option.
Example:

```
/opt/mapr/hive/hive-<version>/bin/hive -i <filename>
```

Setting the Execution Engine

Consider the following definitions:

Term	Definition
runtime	The execution time of the job.
session time	The time from the start of the Hive shell or Beeline until you exit.

You can change the execution engine during a session (session time), but not while executing a job in the session (runtime). If you specify the execution engine before starting the job, it overrides the `hive.execution.engine` property in the `hive-site.xml` file. For example, to specify the execution engine:

```
hive> set hive.execution.engine=tez;
hive> *perform some query here*
```

If you open another Hive shell or Beeline session, you will not see the setting in the session from before, and you can set the needed properties for every session.

 **IMPORTANT:** Hewlett Packard Enterprise strongly recommends configuring Tez as an execution engine instead of an MR execution engine. MR execution engine is deprecated in Hive and is not suitable for use in production environments.

If you are currently using the MR execution engine for accessing Hive CLI and HS2, Hive generates the following warning message:

```
Hive-on-MR is deprecated in Hive 2 and may not be available in the future
versions. Consider using a different execution engine (i.e. spark, tez) or
using Hive 1.X releases.
```

To install and configure Tez as an execution engine for Hive, see [Configuring Hive and Tez](#).

Managing Hive Metastore

The Hive Metastore is started automatically by the warden at installation time if the `mapr-hivemetastore` package is installed. It is sometimes necessary to start or stop the service (for example, after changing the configuration). You can start and stop Hive Metastore in two ways:

- Using the `maprccli node services` command - Using this command, you can start Hive Metastore on multiple nodes at one time.
- Using the Control System

To start Hive Metastore using the `maprccli`:

Procedure

1. Make a list of nodes on which Hive Metastore is configured.
2. Issue the `maprccli node services` command:

```
/opt/mapr/bin/maprccli node services -name hivemeta -action start -nodes
<space delimited list of nodes>
```

To stop Hive Metastore using the maprccli:

Procedure

1. Make a list of nodes on which Hive Metastore is configured.
2. Issue the maprccli node services command:

```
maprccli node services -name hivemeta -action stop -nodes <space
delimited list of nodes>
```

To start or stop Hive Metastore using the Control System:

Procedure

1. In the Navigation pane, expand the Cluster Views pane and click **Dashboard**.
2. In the Services pane, click **Hive Metastore** to open the Nodes screen displaying all the nodes on which Hive Metastore is configured.
3. On the Nodes screen, click the hostname of each node to display its Node Properties screen.
4. On each Node Properties screen, use the **Stop/Start** button in the Hive Metastore row under Manage Node Services to start Hive Metastore.

Managing Hiveserver2

Hiveserver2 is started automatically at installation time by the warden if the mapr-hiveserver2 package is installed. It is sometimes necessary to start or stop the service (for example, after changing the configuration). You can start and stop Hiveserver2 in two ways:

- Using the maprccli node services command - Using this command, you can start Hiveserver2 on multiple nodes at one time.
- Using the Control System

To start Hiveserver2 using the maprccli:

Procedure

1. Make a list of nodes on which Hiveserver2 is configured.
2. Issue the maprccli node services command:

```
maprccli node services -name hs2 -action start -nodes <space delimited
list of nodes>
```

To stop Hiveserver2 using the maprccli:

Procedure

1. Make a list of nodes on which Hiveserver2 is configured.
2. Issue the maprccli node services command:

```
maprccli node services -name hs2 -action stop -nodes <space delimited
list of nodes>
```

To start or stop Hiveserver2 using the Control System:

Procedure

1. In the Navigation pane, expand the Cluster Views pane and click **Dashboard**.
2. In the Services pane, click **Hiveserver2** to open the Nodes screen displaying all the nodes on which Hiveserver2 is configured.
3. On the Nodes screen, click the hostname of each node to display its Node Properties screen.
4. On each Node Properties screen, use the **Stop/Start** button in the Hiveserver2 row under Manage Node Services to start Hiveserver2.

Connecting to Hive

This section contains the following topics:

Connecting to Hive Metastore

The connection requirements Hive Metastore clients use to connect to Hive Metastore is based on the Hive Metastore authentication method:

Authentication Method	Connection Requirements
MapR-SASL	Client nodes require the following: <ul style="list-style-type: none"> • They are configured to use MapR-SASL when authenticating with Hive Metastore. • A valid Data Fabric ticket.
Kerberos	Client nodes require the following: <ul style="list-style-type: none"> • They are configured to use Kerberos when authenticating with Hive Metastore. • A valid Kerberos ticket.
No Authentication	If the cluster is not secure, client nodes do not require any Data Fabric tickets.

Connecting to HMS is provided by the thrift service. You can configure it in hive-site.xml with hive.metastore.uris property:

```
<property>
  <name>hive.metastore.uris</name>
  <value>thrift://<n.n.n.n>:9083</value>
  <description>IP address (or fully-qualified domain name) and port of the
  metastore host</description>
</property>
```

Connecting to HiveServer2

The method that HiveServer2 clients use to connect to HiveServer2 is based on the HiveServer2 Authentication method and the type of client.

Using JDBC or Beeline to Connect to HiveServer2

The HiveServer2 authentication method and client type determine how the HiveServer2 clients connect to HiveServer2.

TIP: For details on how to install and use ODBC to connect to Hive, see [Using ODBC to Connect to HiveServer2](#) on page 5063. When connecting to Hive via ODBC, the client must have a valid Data Fabric or Kerberos ticket.

Using JDBC or Beeline to Connect to HiveServer2

The default port for HiveServer2 is 10000.

The following table lists HiveServer2 authentication mechanisms with the connection parameters required in the JDBC connection string. For a complete list of the JDBC connection string parameters, refer to the next section, Hive JDBC Connection String Parameters.

HiveServer2 Authentication	Connection Requirements
No Authentication	<p>Connection String: jdbc:hive2://<hs2_hostname>:10000<database>; You must enter a valid user name.</p> <p>For encryption, JDBC requires a truststore and an optional truststore password.</p> <ul style="list-style-type: none"> Connection String with Encryption: jdbc:hive2://<hs2_hostname>:10000/<database>; You must enter a valid user name.ssl=true;sslTrustStore=<path-to-truststore>;sslTrustStorePassword=<password> Connection String with Encryption (truststore passed in JVM arguments): jdbc:hive2://<hs2_hostname>:<port>/<database>;ssl=true <p> NOTE: Prior to connecting to an application that uses JDBC, such as Beeline, you can run the following command to pass the truststore parameters as Java arguments:</p> <pre>export HADOOP_OPTS="-Djavax.net.ssl.trustStore=<path-to-trust-store-file> -Djavax.net.ssl.trustStorePassword=<password>"</pre>
MapR-SASL (included as part of the secure by default configuration)	<p>Connection String: jdbc:hive2://<hs2_hostname>:10000/<database>;auth=maprsasl;ssl=true;</p> <p>MapR-SASL encryption is enabled by default. For more information, see Configuring JDBC Connection String with SSL Encryption Enabled or Disabled.</p> <p> NOTE: MapR-SASL is not supported for Hive in HTTP mode.</p> <p>Connection for Java Application: Use the -D flag to append the JVM argument: -Dhadoop.login=maprsasl.</p>
PAM	<p>Connection String: jdbc:hive2://<hs2_hostname>:10000/<database>;user=<user>;password=<password></p>

HiveServer2 Authentication	Connection Requirements
PAM + SSL (included as part of the secure by default configuration)	Connection String: jdbc:hive2:// <hs2_hostname>:10000/ <database>;ssl=true;user=<user>;password=<password>. For more information, see Configuring JDBC Connection String with SSL Encryption Enabled or Disabled .
Kerberos	Connection String: jdbc:hive2:// <hostname>:10000/default;principal=mapr/ <FQDN@REALM> Connection for Java Application: Use the -D flag to append the JVM argument: -Dhadoop.login=hybrid  NOTE: The client nodes must also have a Kerberos ticket and be configured to connect to HiveServer2 to use Kerberos.
LDAP	Connection String: jdbc:hive2:// <hs2_hostname>:10000/ <database>;user=<ldap_user>;password=<ldap_password>
ZooKeeper	Connection String: jdbc:hive2:// <hostname>:<port>,<hostname>:<port>;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=hiveserver2 Example: <pre>hive --service beeline -u 'jdbc:hive2:// zookeeper1.com:5181,zookeeper2.com:5181, zookeeper3.com:5181;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=hiveserver2' -n mapr -p</pre>

Hive JDBC Connection String Parameters

The following example shows a common Hive JDBC connection string:

```
jdbc:hive2://zookeeper_quorum|hs2_host:port/[db]
[;principal=<hs2_principal>/<hs2_host>|_HOST@<KDC_REALM>]
[;transportMode=binary|http][;httpPath=<http_path>]
[;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=<zk_namespace>]
[;auth=maprsasl][;ssl=true|false][;sslKeyStore=<key_store_path>]
[;keyStorePassword=<key_store_password>][;sslTrustStore=<trust_store_path>]
[;trustStorePassword=<trust_store_password>][;twoWay=true|false]
```

The following table lists all the Hive JDBC connection string parameters with default values where applicable:

JDBC Parameter	Default	Comment
zookeeper_quorum		Zookeeper quorum. Used only if HA mode for HiveServer2 is enabled.
hs2_host		The hostname of the node with an active HS2 server running.

port	10000/10001	HiveServer2 port. Defaults to 10000 in binary mode. Defaults to 10001 in HTTP transport mode.
[db]	default	The database name to which you want to connect.
[;principal=<hs2_principal>/<hs2_host> _HOST@<KDC_REALM>]		Kerberos principal. Used with Kerberos security only.
[;transportMode=binary http]	binary	HS2 uses a TThreadPoolServer (from Thrift) for TCP (binary) mode, or a Jetty server for the HTTP mode. HTTP mode is required when a proxy is needed between the client and server, for example, for load balancing or security reasons.
[;httpPath=<http_path>]	cliservice or /	The corresponding HTTP endpoint. The default value is cliservice or /. See conf hive.server2.thrift.http.path
[;serviceDiscoveryMode=zookeeper;zooKeeperNamespace=<zk_namespace>]		<zk_namespace> is the parent node in ZooKeeper used by HiveServer2 when supporting dynamic service discovery.
[;auth=maprsasl]		Used with MapR SASL security.
[;ssl=true false]	false	Used to enable SSL encryption.
[;sslKeyStore=<key_store_path>]	Default value is read from \$MAPR_HOME/conf/ssl-client.xml	This parameter only takes effect when ssl=true. Path is the path to the keystore.
[;keyStorePassword=<key_store_password>]	Default value is read from \$MAPR_HOME/conf/ssl-client.xml	This param will take effect only when ssl=true. Keystore password.
[;sslTrustStore=<trust_store_path>]	Default value is read from \$MAPR_HOME/conf/ssl-client.xml	This param will take effect only when ssl=true. Path is the path to the truststore.
[;trustStorePassword=<trust_store_password>]	Default value is read from \$MAPR_HOME/conf/ssl-client.xml	This parameter only takes effect when ssl=true. Password is the truststore password.
[;twoWay=true false]		HIVE-10447 enabled the JDBC driver to support 2-way SSL in HTTP mode. Currently, HiveServer2 does not support 2-way SSL. This features is useful when there is an intermediate server, such as Knox, which requires the client to support 2-way SSL.

Beeline Examples

This page shows examples for connecting to HiveServer2 using Beeline.

The following table is a guide for interpreting the examples on this page. In the examples, replace the variables (information in brackets) with your site-specific values. Be sure to remove the brackets when you insert your information:

Variable	Description
<hs2_hostname>	The name of the host where HiveServer2 is installed.
<database>	The database name to connect to.
<username>	The JDBC username.
<password>	The password for the JDBC user.
<FQDN@realm>	Fully qualified domain name & Kerberos realm.

Using Beeline with no Encryption and no Authentication

```
hive --service beeline
Beeline version 2.3.3-mapr-1901 by Apache Hive
beeline> !connect jdbc:hive2://<hs2_hostname>:10000/<database>;
Connecting to jdbc:hive2://<hs2_hostname>:10000/<database>;
Enter username for jdbc:hive2://<hs2_hostname>:10000/<database>;: <username>
0: jdbc:hive2://<hs2_hostname>:10000/<database>
```

Using Beeline with Encryption and no Authentication

```
hive --service beeline
Beeline version 2.3.3-mapr-1901 by Apache Hive
beeline> !connect jdbc:hive2://<hs2_hostname>:10000/
<database>;ssl=true;sslTrustStore=truststore.jks;sslTrustStorePassword=tsp
Connecting to jdbc:hive2://<hs2_hostname>:10000/
<database>;ssl=true;sslTrustStore=truststore.jks;sslTrustStorePassword=tsp
Enter username for jdbc:hive2://<hs2_hostname>:10000/
<database>;ssl=true;sslTrustStore=truststore.jks;sslTrustStorePassword=tsp:
<username>
0: jdbc:hive2://<hs2_hostname>:10000/<database>
```

Connecting to HiveServer2 with MapR-SASL Authentication

```
hive --service beeline
Beeline version 2.3.3-mapr-1901 by Apache Hive
beeline> !connect jdbc:hive2://<hs2_hostname>:10000/
<database>;auth=maprsasl;ssl=true
Connecting to jdbc:hive2://<hs2_hostname>:10000/
<database>;auth=maprsasl;ssl=true
19/01/31 12:15:33 [main]: WARN maprsasl.MaprSaslClient: SASL
Server qopProperty: auth-confis different from Client:
auth-conf,auth-int,auth.Using Server one
Connected to: Apache Hive (version 2.3.3-mapr-1901)
Driver: Hive JDBC (version 2.3.3-mapr-1901)
Transaction isolation: TRANSACTION_REPEATABLE_READ
0: jdbc:hive2://<hs2_hostname>:10000/<database>
```

Starting from EEP 6.0.0, with secure by default configuration, it is a default connection string for a secure cluster. For more information, see [Configuring JDBC Connection String with SSL Encryption Enabled or Disabled](#).

Using Beeline with PAM Authentication

```
hive --service beeline
Beeline version 2.3.3-mapr-1901 by Apache Hive
beeline> !connect jdbc:hive2://<hs2_hostname>:10000/<database>;
Connecting to jdbc:hive2://<hs2_hostname>:10000/<database>;
Enter username for jdbc:hive2://<hs2_hostname>:10000/<database>;: <username>
Enter password for jdbc:hive2://<hs2_hostname>:10000/<database>;:
<password>
Connected to: Apache Hive (version 2.3.3-mapr-1901)
Driver: Hive JDBC (version 2.3.3-mapr-1901)
Transaction isolation: TRANSACTION_REPEATABLE_READ
0: jdbc:hive2://<hs2_hostname>:10000/<database>
```

Connecting to HiveServer2 with ZooKeeper

```
hive --service beeline -u
'jdbc:hive2://
zookeeper1.com:5181,zookeeper2.com:5181,zookeeper3.com:5181/;serviceDiscover
yMode=zooKeeper;zooKeeperNamespace=hiveserver2' -n mapr -p
```

Connecting to HiveServer2 with PAM Authentication and SSL Encryption

```
hive --service beeline
Beeline version 2.3.3-mapr-1901 by Apache Hive
beeline> !connect jdbc:hive2://<hs2_hostname>:10000/<database>;ssl=true;
Connecting to jdbc:hive2://<hs2_hostname>:10000/<database>;ssl=true;
Enter username for jdbc:hive2://<hs2_hostname>:10000/<database>: <username>
Enter password for jdbc:hive2://<hs2_hostname>:10000/<database>: <password>
Connected to: Apache Hive (version 2.3.3-mapr)
Driver: Hive JDBC (version 2.3.3-mapr)
Transaction isolation: TRANSACTION_REPEATABLE_READ
0: jdbc:hive2://<hs2_hostname>:10000/<database>
```

Starting from EEP 6.0.0, with secure-by-default configurations, the default connection string is for a secure cluster. For more information, see [Configuring JDBC Connection String with SSL Encryption Enabled or Disabled](#).

Using Beeline with Kerberos

Beeline must pass the Kerberos principal for HiveServer2 in the JDBC connection string. The connection strings you pass to Beeline must use the principal name that you configured for HiveServer2.

The following example shows a sample Beeline authentication with Kerberos:

```
hive --service beeline
Beeline version 2.3.3-mapr-1901 by Apache Hive
beeline> !connect jdbc:hive2://<hs2_hostname>:10000/
<database>;principal=mapr<FQDN@REALM>
Connecting to jdbc:hive2://<hs2_hostname>:10000/<database>;principal=mapr/
<FQDN@REALM>
Transaction isolation: TRANSACTION_REPEATABLE_READ
0: jdbc:hive2://<hs2_hostname>:10000/def>
Connected to: Apache Hive (version 2.3.3-mapr)
Driver: Hive JDBC (version 2.3.3-mapr)
Transaction isolation: TRANSACTION_REPEATABLE_READ
0: jdbc:hive2://<hs2_hostname>:10000/<database>
```

Using Beeline with Encryption but no Authentication (truststore parameters passed as JVM arguments)

```
Hive --service beeline
Beeline version 2.3.3-mapr-1901 by Apache Hive
beeline> !connect jdbc:hive2://<hs2_hostname>:1000/<database>;ssl=true
Connecting to jdbc:hive2://<hs2_hostname>:10000/<database>;ssl=true
Enter username for jdbc:hive2://<hs2_hostname>:10000/<database>;ssl=true:
<username>
Enter password for jdbc:hive2://<hs2_hostname>:10000/<database>;ssl=true:
<password>
Connected to: Apache Hive (version 2.3.3-mapr)
Driver: Hive JDBC (version 2.3.3-mapr)
Transaction isolation: TRANSACTION_REPEATABLE_READ
0: jdbc:hive2://<hs2_hostname>:10000/<database>
```

Generating a Kerberos Ticket

Use the kinit utility to generate the ticket and then use klist to verify that a ticket exists.

```
# kinit <username>/<FQDN@REALM>
# klist

Credentials cache: API:501:9
    Principal: username/<FQDN@REALM>
    Cache version: 0

Server: krbtgt/<FQDN@REALM>
Client: username/<FQDN@REALM>
Ticket etype: aes128-cts-hmac-sha1-96
Ticket length: 256
Auth time:   Jun 11 10:01:48 2014
End time:    Jun 12 18:01:34 2014
Renew till:  Jun 18 10:01:48 2014
Ticket flags: pre-authent, initial, renewable, forwardable
Addresses: addressless
```

Configuring JDBC Connection String with SSL Encryption Enabled or Disabled

You can configure a JDBC connection string with SSL encryption enabled or disabled.

SSL encryption to HiveServer2 is enabled (hive.server2.use.SSL=true)

The following table describes the JDBC connection string when SSL encryption is enabled between the Hive client and HiveServer2.

Table

Authentication Type	JDBC Parameter	Example
PAM	ssl=true	jdbc:hive2://<hostname>:10000/default;ssl=true <login><password>
MapR-SASL	ssl=true	jdbc:hive2://<hostname>:10000/default;auth=maprsasl;ssl=true
Kerberos	ssl=true	jdbc:hive2://<hostname>:10000/default;principal=<user/fqdn@EXAMPLE.COM>;ssl=true

SSL encryption to HiveServer2 is disabled (hive.server2.use.SSL=false)

The following table describes the JDBC connection string when SSL encryption is disabled between the Hive client and HiveServer2.

Table

Authentication Type	JDBC Parameter	Example
PAM	--	jdbc:hive2:// <hostname>:10000/default; <login> <password>
MapR-SASL	--	jdbc:hive2:// <hostname>:10000/ default;auth=maprsasl
Kerberos	--	jdbc:hive2:// <hostname>:10000/ default;principal=<user/ fqdn@EXAMPLE.COM

Using ODBC to Connect to HiveServer2

This section contains details about setting up and using the ODBC Connector for Hive.

Before You Begin

The Data Fabric Hive ODBC Connector is an ODBC driver for Apache Hive 0.7.0 and later that complies with the ODBC 3.52 specification. You can download the Hive ODBC connector from https://package.ezmeral.hpe.com/tools/MapR-ODBC/MapR_Hive/. To access the repository, see [Using the HPE Data Fabric Token-Authenticated Internet Repository](#) on page 153.

After downloading the driver, refer to the documentation for [Hive ODBC Driver](#) to install and configure the driver. The [Hive ODBC Driver](#) supports the following Advanced Options:

- Enable Auto Reconnect
- Driver Config Take Precedence
- Fast SQL Prepare
- Get Tables With Query
- Invalid Session Auto Recover
- Show System Table
- Socket Timeout
- Default String Column Length
- Rows Fetched Per Block
- Use Native Query

To use the ODBC driver, configure a *Data Source Name* (DSN), a definition that specifies how to connect to Hive. DSNs are typically managed by the operating system and may be used by multiple applications. Some applications do not use DSNs. You will need to refer to your particular application's documentation to understand how it connects using ODBC.

The standard query language for ODBC is SQL. HiveQL, the standard query language for Hive, includes a subset of ANSI SQL-92. Applications that connect to Hive using ODBC may need queries altered if the

queries use SQL features that are not present in Hive. Applications that use SQL will recognize HiveQL, but might not provide access to HiveQL-specific features such as multi-table insert.

Please refer to the [Hive Language Manual](#) for up-to-date information on HiveQL.

The SQL Connector

The SQL Connector feature translates standard SQL-92 queries into equivalent HiveQL queries. The SQL Connector performs syntactical translations and structural transformations. For example:

- Quoted Identifiers: When quoting identifiers, HiveQL uses back quotes (`), while SQL uses double quotes ("). Even when a driver reports the back quote as the quote character, some applications still generate double-quoted identifiers.
- Table Aliases: HiveQL does not support the AS keyword between a table reference and its alias.
- The JOIN, INNER JOIN, and CROSS JOIN SQL syntaxes are translated to the HiveQL JOIN syntax.
- SQL TOP N queries are transformed to HiveQL LIMIT queries.

Hive ODBC Connector on Linux

System Requirements

- The 32-bit and 64-bit version of the following operating systems:
 - Red Hat® Enterprise Linux® (RHEL) 6 or 7
 - SUSE Linux Enterprise Server (SLES) 11 or 12
 - Debian 8 or 9
 - Ubuntu 14.04, 16.04, or 18.04
- 45 MB of available disk space.
- An installed ODBC driver manager:
 - iODBC 3.52.7 or above (OR)
 - unixODBC 2.2.12 or above

The HPE Data Fabric ODBC Driver with SQL Connector for Apache Hive requires a Hadoop cluster with the Hive service installed and running. The HPE Data Fabric ODBC Driver with SQL Connector for Apache Hive is suitable for use with all versions of Hive. Download the ODBC connector from the following location: [MapR_Hive](#).

IMPORTANT: To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see [Using the HPE Data Fabric Token-Authenticated Internet Repository](#) on page 153.

The RPM files are applicable for:

- Red Hat® Enterprise Linux® (RHEL) 6 or 7
- SUSE Linux Enterprise Server (SLES) 11 or 12

The DEB files are applicable for:

- Debian 8 or 9
- Ubuntu 14.04, 16.04, or 18.04

The latest version of the Hive ODBC connector is at version 2.6.14.1014.

Install the Hive ODBC Connector on Linux

About this task

The Data Fabric ODBC Driver with SQL Connector for Apache Hive driver files are installed in the following directories:

- /opt/mapr/hiveodbc/ErrorMessage – Error messages files directory
- /opt/mapr/hiveodbc/Setup – Sample configuration files directory
- /opt/mapr/hiveodbc/lib/32 – 32-bit shared libraries directory
- /opt/mapr/hiveodbc/lib/64 – 64-bit shared libraries directory

To install the Data Fabric ODBC Driver with SQL Connector for Apache Hive:

Procedure

1. Log in as the root user.
2. Use RPM to install the rpm package corresponding to your Linux distribution:
 - [32-bit](#)
 - [64-bit](#)

The Data Fabric ODBC Driver with SQL Connector for Apache Hive depends on the following resources:

- cyrus-sasl-2.1.22-7 or later
- cyrus-sasl-gssapi-2.1.22-7 or later
- cyrus-sasl-plain-2.1.22-7 or later

If the package manager in your Linux distribution cannot resolve the dependencies automatically when installing the driver, download and manually install the packages required by the version of the driver that you want to install.

Configure the Hive ODBC Connector Driver on Linux

The LD_LIBRARY_PATH environment variable must include the paths to the:

- Libraries for the installed ODBC driver manager
- Shared libraries for the Data Fabric ODBC Driver with SQL Connector for Apache Hive

Important: The Linux version of the driver bundles together functionality for both 32-bit and 64-bit environments. Do not include the paths to both 32- and 64-bit shared libraries in LD_LIBRARY_PATH at the same time. Include only the path to the shared libraries corresponding to the driver matching the bitness of the client application used. For example, if you are using a 64-bit client application and ODBC driver manager libraries are installed in /usr/local/lib, then set LD_LIBRARY_PATH as follows:

```
export LD_LIBRARY_PATH=/usr/local/lib:/opt/mapr/hiveodbc/lib/64
```

For more information about how to set environment variables permanently, refer to your Linux shell documentation.

Configuring ODBC Connections for Linux

Files

ODBC driver managers use configuration files to define and configure ODBC data sources and drivers. By default, the following configuration files residing in the user's home directory are used:

- `.odbc.ini` – The file used to define ODBC data sources (required)
- `.odbcinst.ini` – The file used to define ODBC drivers (optional)
- `.mapr.hiveodbc.ini` – The file used to configure the Data Fabric ODBC Driver with SQL Connector for Apache Hive (required)

Sample Files

The driver installation contains the following sample configuration files in the Setup directory:

- `odbc.ini`
- `odbcinst.ini`
- `mapr.hiveodbc.ini`

The names of the sample configuration files do not begin with a period (.) so that they will appear in directory listings by default. A filename beginning with a period (.) is hidden. For `odbc.ini` and `odbcinst.ini`, if the default location is used, then the filenames must begin with a period (.) . For `mapr.hiveodbc.ini`, the filename must begin with a period (.) and must reside in the user's home directory. If the configuration files do not already exist in the user's home directory, then the sample configuration files can be copied to that directory and renamed. If the configuration files already exist in the user's home directory, then the sample configuration files should be used as a guide for modifying the existing configuration files.

Configuring the Environment

By default, the configuration files reside in the user's home directory. However, two environment variables, `ODBCINI` and `ODBCSYSINI`, can be used to specify different locations for the `odbc.ini` and `odbcinst.ini` configuration files. Set `ODBCINI` to point to your `odbc.ini` file. Set `ODBCSYSINI` to point to the directory containing the `odbcinst.ini` file. For example, if your `odbc.ini` file is located in `/etc` and your `odbcinst.ini` file is located in `/usr/local/odbc`, then set the environment variables as follows:

```
export ODBCINI=/etc/odbc.ini export ODBCSYSINI=/usr/local/odbc
```

```
export ODBCINI=/etc/odbc.ini export ODBCSYSINI=/usr/local/odbc
```

For version 2.1.8 and above, you must also set `MAPRHIVEINI` to point to the `mapr.hiveodbc.ini` file in the user's home directory:

```
export MAPRHIVEINI=/etc/.mapr.hiveodbc.ini
```

For version 2.1.5 and below, you set `MAPRINI` to point to the `mapr.hiveodbc.ini` file in the user's home directory:

```
export MAPRINI=/<user_home>/mapr.hiveodbc.ini
```

Configuring the `odbc.ini` File

ODBC Data Sources are defined in the `odbc.ini` configuration file. The file is divided into several sections:

- `[ODBC]` is optional and used to control global ODBC configuration, such as ODBC tracing.
- `[ODBC Data Sources]` is required, listing DSNs and associating DSNs with a driver.

- A section having the same name as the data source specified in the [ODBC Data Sources] section is required to configure the data source.

Here is an example `odbc.ini` configuration file for Linux:

```
[ODBC Data Sources]
Sample MapR Hive DSN 32=MapR Hive ODBC Driver 32-bit
[Sample MapR Hive DSN 32]
Driver=/opt/mapr/hiveodbc/lib/32/libmaprhiveodbc32.so
HOST=MyHiveServer
PORT=10000
```

To create a data source:

1. Open the `.odbc.ini` configuration file in a text editor.
2. Add a new entry to the [ODBC Data Sources] section. Type the data source name (DSN) and the driver name.
3. To set configuration options, add a new section having a name matching the data source name (DSN) you specified in step 2. Specify configuration options as keyvalue pairs.
4. Save the `.odbc.ini` configuration file.

NOTE: You can set configuration options in your `odbc.ini` and `.mapr.hiveodbc.ini` files. Configuration options set in a `.mapr.hiveodbc.ini` file apply to all connections, whereas configuration options set in an `odbc.ini` file are specific to a connection. Configuration options set in `odbc.ini` take precedence over configuration options set in `.mapr.hiveodbc.ini`.

Configuring the `odbcinst.ini` File

ODBC Drivers are defined in the `odbcinst.ini` configuration file. The configuration file is optional because drivers can be specified directly in the `odbc.ini` configuration file. The `odbcinst.ini` file is divided into the following sections:

- [ODBC Drivers] lists the names of all the installed ODBC drivers.
- section having the same name as the driver name specified in the [ODBC Drivers] section lists driver attributes and values.

Here is an example `odbcinst.ini` file for Linux:

```
[ODBC Drivers]
MapR Hive ODBC Driver 32-bit=Installed
MapR Hive ODBC Driver 64-bit=Installed
[MapR Hive ODBC Driver 32-bit]
Description=MapR Hive ODBC Driver (32-bit)
Driver=/opt/mapr/hiveodbc/lib/32/libmaprhiveodbc32.so
[MapR Hive ODBC Driver 64-bit]
Description=MapR Hive ODBC Driver (64-bit)
Driver=/opt/mapr/hiveodbc/lib/64/libmaprhiveodbc64.so
```

To define a driver:

1. Open the `.odbcinst.ini` configuration file in a text editor.

2. Add a new entry to the [ODBC Drivers] section. Type the driver name, and then type **=Installed**

NOTE: Assign the driver name as the value of the Driver attribute in the data source definition instead of the driver shared library name.

3. In `.odbcinst.ini`, add a new section having a name matching the driver name you typed in step 2, and then add configuration options to the section based on the sample `odbcinst.ini` file provided with the MapR ODBC Driver with SQL Connector for Apache Hive in the Setup directory. Specify configuration options as keyvalue pairs.
4. Save the `.odbcinst.ini` configuration file.

Configuring the `mapr.hiveodbc.ini` File

Describes how to configure the Data Fabric ODBC Driver with SQL Connector for Apache Hive to work with your ODBC driver manager.

About this task

To configure the Data Fabric ODBC Driver with SQL Connector for Apache Hive to work with your ODBC driver manager:

Procedure

1. Open the `.mapr.hiveodbc.ini` configuration file in a text editor.

The following is an example of the `.mapr.hiveodbc.ini` file template:

```
[Driver]

ErrorMessagesPath=/opt/mapr/hiveodbc/ErrorMessage/
LogLevel=0
LogPath=
SwapFilePath=/tmp
```

2. Edit the `DriverManagerEncoding` setting. The value usually must be UTF-16 or UTF-32, depending on the ODBC driver manager you use. iODBC uses UTF-32 and unixODBC uses UTF-16. Consult your ODBC Driver Manager documentation for the correct setting to use.

3. Edit the `ODBCInstLib` setting. The value is the name of the `ODBCInst` shared library for the ODBC driver manager you use. The configuration file defaults to the shared library for `iODBC`. In Linux, the shared library name for `iODBC` is `libiodbcinst.so`.

NOTE: Consult your ODBC driver manager documentation for the correct library to specify. You can specify an absolute or relative filename for the library. If you intend to use the relative filename, then the path to the library must be included in the library path environment variable. In Linux, the library path environment variable is named `LD_LIBRARY_PATH`.

The following is an example of the `.mapr.hiveodbc.ini` file with filled `DriverManagerEncoding` and `ODBCInstLib` settings:

```
$ cat /etc/.mapr.hiveodbc.ini

[Driver]

ErrorMessagesPath=/opt/mapr/hiveodbc/ErrorMessage/
LogLevel=0
LogPath=
SwapFilePath=/tmp

#add for unixODBC
DriverManagerEncoding=UTF-16
ODBCInstLib=libodbcinst.so
```

4. Save the `.mapr.hiveodbc.ini` configuration file.

Configuring Authentication

You can configure the following types of authentication:

- No authentication
- MapR-SASL
- User name
- User name and password
- Kerberos

When `hive.server2.authentication` is set to `KERBEROS`, then you must configure your connection to use Kerberos.

To find out the authentication setting your Hive Server 2 is set to use, review the following properties in the `hive-site.xml` file:

- `hive.server2.authentication`
- `hive.server2.enable.doAs`

Using No Authentication

To use no authentication, set the `AuthMech` configuration key for the DSN to 0.

Using MapR-SASL

To configure MapR-SASL SASL in `odbc.ini`, set the following option:

```
AuthMech=13
```

Using User Name

To configure User Name authentication:

1. Set the AuthMech configuration key for the DSN to 2.
2. Set the UID key to the appropriate user name recognized by the Hive server.

Using User Name and Password

To configure User Name and Password authentication:

1. Set the AuthMech configuration key for the DSN to 3.
2. Set the UID key to the appropriate user name recognized by the Hive server.
3. Set the PWD key to the password corresponding to the user name you provided in step 2.

Using Kerberos

To configure Kerberos authentication:

1. Set the H2SAuthMech configuration key for the DSN to 1.
2. If your Kerberos setup does not define a default realm or if the realm of your Hive server is not the default, then set the appropriate realm using the HS2KrbRealm key.
3. Set the HS2HostFQDN key to the fully qualified domain name of the Hive Server 2 host.
4. Set the HS2KrbServiceName key to the service name of the Hive Server 2 host.

Hive ODBC Connector on Windows

There are versions of the connector for 32-bit and 64-bit applications. The 64-bit version of the connector works only with 64-bit DSNs; the 32-bit connector works only with 32-bit DSNs. Because 64-bit Windows machines can run both 64-bit and 32-bit applications, install both versions of the connector in order to set up DSNs to work with both types of applications. If both the 32-bit connector and the 64-bit connector are installed, you must configure DSNs for each independently, in their separate Data Source Administrators.

Install the Hive ODBC Connector on Windows**About this task**

To use MapR Hive ODBC Connector on Windows requires:

- Windows® 7 Professional or Windows® 2008 R2. Both 32 and 64-bit editions are supported.
- The Microsoft Visual C++ 2010 Redistributable Package (runtimes required to run applications developed with Visual C++ on a computer that does not have Visual C++ 2010 installed.)
- A Hadoop cluster with the Hive service installed and running. You should find out from the cluster administrator the hostname or IP address for the Hive service and the port that the service is running on. (The default port for Hive is 10000.)

Procedure

1. Download and run the ODBC connector.

Download the ODBC connector from the following location: [MapR_Hive](#). Select either the 64-bit or 32-bit connector.

IMPORTANT: To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see [Using the HPE Data Fabric Token-Authenticated Internet Repository](#) on page 153.

2. Accept the license agreement.
3. Select an installation folder.
4. On the Information window, click **Next**.
5. On the Completing... window, click **Finish**.
6. Install a DSN corresponding to your Hive server.

Configure Hive ODBC Connections on Windows

About this task

To create a Data Source Name (DSN)

Procedure

1. Open the Data Source Administrator from the Start menu. Example: **Start > MapR Hive ODBC Driver 2.0 > 64-Bit ODBC Driver Manager**
2. On the **User DSN** tab click **Add** to open the Create New Data Source dialog.

3. Select **MapR Hive ODBC Connector** and click **Finish** to open the Hive ODBC Driver DSN Setup window.

4. Enter the connection information for the Hive instance:

The image shows a Windows-style dialog box titled "MapR Hive ODBC Connector DSN Setup". It contains various input fields and dropdown menus for configuring a DSN. The fields are organized into sections: general DSN information, authentication, and transport options. At the bottom, there are buttons for "Advanced Options...", "Logging Options...", "Test", "OK", and "Cancel". The version "v2.6.1.1001 (64 bit)" is displayed in the bottom left corner.

MapR Hive ODBC Connector DSN Setup

Data Source Name: HiveServer2 on MapR

Description:

Hive Server Type: Hive Server 2

Service Discovery Mode: No Service Discovery

Host(s): hivenode

Port: 10000

Database: default

ZooKeeper Namespace:

Authentication

Mechanism: User Name and Password

Realm:

Host FQDN: _HOST

Service Name: hive

☒ Canonicalize Principal FQDN

☐ Delegate Kerberos Credentials

User Name: mapr

Password: ••••

☐ Save Password (Encrypted)

Delegation UID:

Thrift Transport: SASL

HTTP Options SSL Options

Advanced Options... Logging Options...

v2.6.1.1001 (64 bit) Test OK Cancel

- **Data Source Name** — Specify a name for the DSN.
- **Description** — Enter an optional description for the DSN.
- **Host** — Enter the hostname or IP of the server running HiveServer1 or HiveServer2.
- **Port** — Enter the listening port for the Hive service.

- **Database** — Leave as default to connect to the default Hive database, or enter a specific database name.
 - **Hive Server Type:** — Set to HiveServer1 or HiveServer2.
 - **Authentication** — If you are using HiveServer2, set the following.
 - **Mechanism:** — Set to the authentication mechanism you're using. The MapR ODBC driver supports user name, user name and password, username and password over SSL authentication, and Kerberos.
 - **User Name:** — Set the user to run queries as.
 - **Password:** — The user's password, if your selected authentication mechanism requires one.
5. Optionally, click **Test** to test the connection.
 6. Click OK.

Your new connector will appear in the User Data Sources list.

What to do next

For steps to apply custom configurations, see [Hive ODBC Driver](#).

Hive ODBC Connector on Mac OS X

System Requirements

- Mac OS X version 10.6.8 or later
- 100 MB of available disk space
- iODBC 3.52.7 or above
- unixODBC 2.2.12 or above

The Data Fabric ODBC Driver with SQL Connector for Apache Hive requires a Hadoop cluster with the Hive service installed and running. The Data Fabric ODBC Driver with SQL Connector for Apache Hive is suitable for use with all versions of Hive. The driver supports both 32- and 64-bit client applications.

Download the MacOS Hive ODBC connector from [MapR_Hive](#).

IMPORTANT: To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see [Using the HPE Data Fabric Token-Authenticated Internet Repository](#) on page 153.

Installation

The Data Fabric ODBC Driver with SQL Connector for Apache Hive driver files are installed in the following directories:

- /opt/mapr/hiveodbc/ErrorMessage – Error messages files directory
- /opt/mapr/hiveodbc/Setup – Sample configuration files directory
- /opt/mapr/hiveodbc/lib/universal – Binaries directory

To install the Data Fabric ODBC Driver with SQL Connector for Apache Hive:

1. Double-click to mount the MapRHiveODBC.dmg disk image.
2. Double-click MapRHiveODBC.pkg to run the Installer.
3. Follow the instructions in the Installer to complete the installation process.
4. When the installation completes, click **Close**.

Configuration

Setting the DYLD_LIBRARY_PATH Environment Variable

The DYLD_LIBRARY_PATH environment variable must include the paths to:

- Installed ODBC driver manager libraries
- Installed Data Fabric ODBC Driver with SQL Connector for Apache Hive shared libraries

For example, if ODBC driver manager libraries are installed in /usr/local/lib, then set DYLD_LIBRARY_PATH as follows:

```
export DYLD_LIBRARY_PATH=/usr/local/lib/opt/mapr/hiveodbc/lib/universal
```

Refer to your Mac OS X shell documentation for details on how to set environment variables permanently.

Configure Hive ODBC Connections on Mac OS X

See [Configuring ODBC Connections for Linux](#) for details on creating ODBC connections.

Configuring Encryption for ODBC Connection

Explains how to configure SSL encryption between ODBC connection to Hiveserver2 on non-secure cluster.

About this task

Hive uses cyrus-sasl-plain package for ODBC connection.

Procedure

1. Generate ssl_keystore/ssl_truststore by running the following command:

```
sudo bash /opt/mapr/server/manageSSLKeys.sh create -ug mapr:mapr
```

IMPORTANT: Make a note of the CN=HOST_NAME parameter in the output.

2. Configure SSL for Hive as described in [Configure Encryption without Authentication](#) on page 4981.
3. Generate the .pem file. To generate:
 - a) Verify that ssl_keystore and ssl_truststore are present on the system.

```
cd /opt/mapr/conf
ll *ssl*store*
```

If ssl_keystore and ssl_truststore are not present, then generate them.

- b) Generate .pem file using <ssl-keystore-password> password.

```
keytool -importkeystore -srckeystore ssl_keystore -destkeystore
ssl_keystore.p12 -srcstoretype jks -deststoretype pkcs12
```

- c) Verify that the `ssl_keystore.p12` and `ssl_keystore.pem` files are created.

For example:

```
openssl pkcs12 -in ssl_keystore.p12 -out ssl_keystore.pem
openssl x509 -text -in ssl_keystore.pem
```

4. Configure SSL for ODBC driver by making the following changes in the `/etc/odbc.ini`, `/etc/odbcinst.ini`, and `/etc/mapr.hiveodbc.init` files. That is, in the:

- `/etc/odbc.ini` file:
 - a. Replace `<HOST_NAME>` with the host name.
 - b. Set the value for `TrustedCerts` to path to `ssl_keystore.pem` file.
 - c. Add the following to the file:

```
[ODBC Data Sources]
Sample MapR Hive DSN=Hive Hive ODBC Driver 64-bit
[Hive]
Driver=/opt/mapr/hiveodbc/lib/64/libmaprhiveodbc64.so
HOST=<HOST_NAME>
PORT=10000
SSL=1
CAIssuedCertNamesMismatch=1
TrustedCerts=/opt/mapr/conf/ssl_keystore.pem
AuthMech=4
```

- `/etc/odbcinst.ini` file, add the following:

```
[ODBC Drivers]
MapR Hive ODBC Driver=Installed
[MapR Hive ODBC Driver 64-bit]
Description=MapR Hive ODBC Driver (64-bit)
Driver=/opt/mapr/hiveodbc/lib/64/libmaprhiveodbc64.so
```

- `etc/mapr.hiveodbc.ini` file, add the following:

```
[Driver]
ErrorMessagesPath=/opt/mapr/hiveodbc/ErrorMessage/
LogLevel=0
LogPath=
SwapFilePath=/tmp
```

Example

Sample `/etc/odbc.ini` file

```
[ODBC Data Sources]
Sample MapR Hive DSN=Hive Hive ODBC Driver 64-bit
[Hive]
Driver=/opt/mapr/hiveodbc/lib/64/libmaprhiveodbc64.so
HOST=<HOST_NAME>
PORT=10000
SSL=1
CAIssuedCertNamesMismatch=1
TrustedCerts=/opt/mapr/conf/ssl_keystore.pem
AuthMech=4
```

Sample /etc/odbcinst.ini file

```
[ODBC Drivers]
Mapr Hive ODBC Driver=Installed
[Mapr Hive ODBC Driver 64-bit]
Description=Mapr Hive ODBC Driver (64-bit)
Driver=/opt/mapr/hiveodbc/lib/64/libmaprhiveodbc64.so
```

Sample /etc/mapr.hiveodbc.ini file

```
[Driver]
ErrorMessagePath=/opt/mapr/hiveodbc/ErrorMessage/
LogLevel=0
LogPath=
SwapFilePath=/tmp
```

Connecting to WebHCat

The method that WebHCat clients use to connect to WebHCat is based on the WebHCat Authentication method:

WebHCat Authentication	Connection Requirements
Simple	<p>Clients pass the username as the user . name parameter in the REST call. No password is required. Example:</p> <pre>http://<hostname>:50111/templeton/v1/ddl/database/default/table/table01?user.name=juser</pre>
PAM	<p>Clients enter username and password authentication through a pop-up dialog box in the web browser session.</p>
Kerberos with SPNEGO	<p>Clients can use one of the following methods:</p> <ul style="list-style-type: none"> curl example: <pre>curl --negotiate -i -u : 'http://<FQDN>:50111/templeton/v1/ddl/database/'</pre> Web browser with user name and password. For more information, see Configuring SPNEGO on Data Fabric on page 2114 <p> NOTE: With either method you must also have a Kerberos ticket in the cache. See Example: Generating a Kerberos Ticket</p>

Enabling High Availability for Hive

This section describes how to enable High Availability for HiveServer2 and HiveMetastore.

NOTE: You can achieve High Availability(HA) through HA tools like HAProxy or F5. Based on the tools used, you need to configure reverse DNS lookups and implement other security features. However, the HPE Data Fabric does not support any HA tool.

Related concepts

[Enabling High Availability for Spark Thrift Server](#) on page 5437

Enabling High Availability for HiveServer2

About this task

Perform the following steps to enable High Availability for HiveServer2.

Configuring Hive

Procedure

- 1. Modify the warden.hs2.conf file as shown below on all the nodes where Hive is installed.

```
services=hs2:all
```

- 2. Add the following properties to the hive-site.xml file on all the nodes where HiveServer2 is installed.

Property	Value	Description
hive.server2.support.dynamic.service.discovery	true (default is false)	Set to true to enable HiveServer2 dynamic service discovery for its clients.
hive.server2.zookeeper.namespace	hiveserver2 (default value)	The parent node in ZooKeeper, which is used by HiveServer2 when supporting dynamic service discovery.
hive.zookeeper.quorum	<hostname>:5181,<hostname>:5181,<hostname>:5181	List of ZooKeeper servers to talk to. Used in connection string by JDBC/ODBC clients instead of URI of specific HiveServer2 instance.
hive.zookeeper.client.port	5181 (default value)	The port of the ZooKeeper servers to talk to. If the list of Zookeeper servers specified in hive.zookeeper.quorum does not contain port numbers and so, this value is used.
hive.zookeeper.session.timeout	600000 (default value)	Zookeeper client's session timeout value. The client is disconnected, and as a result, all locks are released if a heartbeat is not sent within the timeout period.

- 3. Restart all the nodes where Hive service is installed after updating the configuration.

Connecting with JDBC/ODBC Clients

Procedure

- Connect to HiveServer2 with JDBC/ODBC clients using the following connection string:

```
jdbc:hive2://<zookeeper_ensemble>;serviceDiscoveryMode=zooKeeper;  
zooKeeperNamespace=<hiveserver2_zookeeper_namespace>
```

Here:

<zookeeper_ensemble>	Specifies a comma-separated list of ZooKeeper servers that form the ensemble. For example: <zk_host1>:<zk_port1>,<zk_host2>:<zk_port2>,<zk_host3>:<zk_port3>
<hiveserver2_zookeeper_namespace>	Specifies the namespace on Zookeeper under which HiveServer2 znodes are added. The namespace value is configured in hive.server2.zookeeper.namespace

*Deregistering HiveServer2 Instances from Zookeeper***About this task**

Remove a HiveServer2 instance from Zookeeper by running the following commands (in the ZooKeeper command line interface) to deregister the server.

Procedure

1. Launch the ZooKeeper command line interface and get the HiveServer2 znode by running the following commands:

```
/opt/mapr/zookeeper/zookeeper-<version>/bin/zkCli.sh -server <ip:port of
zookeeper instance>
ls /<hive.server2.zookeeper.namespace>
```

2. Run the command to deregister HiveServer2. To deregister:

- A particular HiveServer2, run the following command:

```
delete /hiveserver2 serverUri=<hostname:port>;version=<hive
version>;sequence=<sequence number>
```

After you deregister the HiveServer2 from Zookeeper, it will not return the deregistered HiveServer2 for new client connections. However, active client sessions are not affected by deregistering the HiveServer2 from Zookeeper.

- All HiveServer2 instances of a particular version, run the following command:

```
hive --service hiveserver2 --deregister <version_number>
```

Example HiveServer2 High Availability Setup

This section describes a High Availability set up for HiveServer2 on a sample HPE Data Fabric cluster. Suppose a three-node cluster with the following (optional) IP addresses and host names:

IP Address	Host Name
192.168.33.11	node1
192.168.33.12	node2
192.168.33.13	node3

Use the following string to connect to the HiveServer2:

```
jdbc:hive2://
node1:5181,node2:5181,node3:5181/;serviceDiscoveryMode=zooKeeper;zooKeeperNa
mespace=hiveserver2
```

To deregister HiveServer2:

1. Launch the ZooKeeper command-line interface using the following command:

```
/opt/mapr/zookeeper/zookeeper-3.5.6/bin/zkCli.sh -server
192.168.33.13:5181
```

2. Look at the ZooKeeper namespace using the following command:

```
ls /hiveserver2
```

Output:

```
[serverUri=node3:10000;version=2.1.1-mapr-1703;sequence=0000000004,  
serverUri=node1:10000;version=2.1.1-mapr-1703;sequence=0000000006]
```

3. Deregister:

- HiveServer2 on node3:

```
delete  
serverUri=node3:10000;version=2.1.1-mapr-1703;sequence=0000000004
```

- All HiveServer2 instances:

```
hive --service hiveserver2 --deregister 2.1.1-mapr-1703
```

Enabling High Availability for Hive Metastore

About this task

To enable High Availability for Hive Metastore.

Procedure

1. Enable remote access to the underlying database from different nodes.
2. Add all Metastore instances to `hive.metastore.uris` on all the nodes, as a list of comma-separated values.

```
<property>  
  <name>hive.metastore.uris</name>  
  <value>thrift://<hostname1>:9083,thrift://<hostname2>:9083</value>  
</property>
```

3. Restart Hive Metastore services on all nodes, where Hive Metastore services are installed.
4. Restart all HiveServer2 instances.

Results

Enabling high availability for the Hive Metastore does not require changes to the `warden.hivemetastore.conf` file. Active-active mode is not supported for Hive Metastore. Hence, there is one active instance of the Hive Metastore service at any given point in time. The other instances of the Hive Metastore service are in standby state.

You can check the state of Hive Metastore service on the Control System.

Example

Suppose that Hive Metastore is installed on three nodes, node1, node2, node3, while MySQLServer is installed on node3, as given below.

IP Address	Host Name
192.168.33.11	node1
192.168.33.12	node2
192.168.33.13	node3

1. Change the MySQL configuration:

```
nano /etc/my.cnf
```

2. Comment out the following properties:

```
#bind-address
#skip-networking
```

If these properties are not in my.cnf, you can skip editing my.cnf. Restart the MySQL server.

3. Enable remote access for the underlying database by granting permissions in the underlying database. Connect to MySQL server from node3, and provide access to node1 and node2.

```
mysql> GRANT ALL PRIVILEGES ON metastore.* TO 'root'@'192.168.33.11'
IDENTIFIED BY 'secret' WITH GRANT OPTION;
mysql> GRANT ALL PRIVILEGES ON metastore.* TO 'root'@'192.168.33.12'
IDENTIFIED BY 'secret' WITH GRANT OPTION;
mysql> flush privileges;
```

4. Optionally, verify the connectivity to the MySQL server running on node3 from node1 and node2. For example, run the following commands:

- On node1:

```
mysql -h node3 -uroot -psecret
```

- On node2:

```
mysql -h node3 -uroot -psecret
```

5. Add all Metastore instances to hive.metastore.uris on all nodes with the Hive instance:

```
<property>
  <name>hive.metastore.uris</name>
  <value>thrift://192.168.33.11:9083,thrift://
192.168.33.12:9083,thrift://192.168.33.13:9083 </value>
</property>
```

6. Restart Hive Metastore services on all nodes where Hive Metastore service is installed and then all HiveServer2 instances.

```
maprcli node services -name hivemeta -action restart -nodes
<comma-separated list of Hive Metastore nodes>
```

7. Restart all HiveServer2 instances.

```
maprcli node services -name hs2 -action restart -nodes <comma-separated list of HiveServer2 nodes>
```

Check the status of Hive Metastore on the Control System. Following is a sample view of the Control System displaying the status of Hive Metastore.

All (23)

Service	Running Nodes	Standby Nodes	Failed Nodes	Stopped Nodes
MEP				
Data Access Gateway	2	0	0	0
HBase Rest Server	3	0	0	0
HBase Thrift Server	1	0	0	0
HBase Master	2	0	0	0
HBase Region Server	3	0	0	0
Yarn Server	3	0	0	0
Tez UI	1	0	0	0
Timeline Server	1	0	0	0
Hive				
• HiveServer2	1	0	0	0
• Hive Metastore	1	2	0	0
• WebHCat	1	0	0	0

Hive Features in HPE Data Fabric

Describes HPE Data Fabric-specific features in Hive.

Removing Temporary Hive Files

Starting from EEP 8.1.0, EEP 7.1.2, and EEP 6.3.6, to remove the temporary Hive files created during the Hive session, set the value of `hive.scratchdir.lock` property to `true` on `hive-site.xml` file.

```
<property>
  <name>hive.scratchdir.lock</name>
  <value>true</value>
</property>
```

For the previous EEP versions, manually remove the temporary Hive files that are not used by the active Hive sessions.

You have two different situations:

- If you have configured the HiveServer2 in a node, set `hive.scratchdir.lock` property on the `hive-site.xml` file to automatically remove the temporary Hive files.
- If you have not configured the HiveServer2 in a node, set the `hive.scratchdir.lock` property and run the following command to remove the temporary Hive files.

```
hive --service cleardanglingscratchdir
```

Symbolic Link Support in Hive

Starting from EEP 7.1.0, all [hadoop fs](#) commands support operations on symlinks (symbolic links). Hive supports symlinks in EEP 8.0.0 onwards. You can create symlinks through the command line interface or file system API (MapRFileSystem.java).

Symlink creation via CLI has the following requirements:

- [NFS installed](#)
- [NFS mounted](#) (mount hadoop fs to the local file system)

Creating Symlinks

The following examples demonstrate how to create symbolic links via CLI and MapRFileSystem API:

- Create a *relative* symlink via CLI:

```
ln -rs /mountPoint/path/to/file /
mountPoint/path/to/symlink
```

- Create an *absolute* symlink via CLI:

```
ln -s /mountPoint/path/to/file /
mountPoint/path/to/symlink
```

- Create a symlink via MapRFileSystem API:

```
MapRFileSystem maprFS =
MapRFileSystem.get(new
Configuration());
maprFS.createSymlink(pathToTarget,
pathToLink, createParentFlag);
```

Using Symlinks for Hive Operations

Once a symlink is created, you can use the symlink for Hive operations, such as table location and data file, as demonstrated in the following steps:

1. Create a table directory:

```
mkdir /mapr/my.cluster.com/user/
hive/warehouse/ext_tbl_symlink
```

2. Create a symlink from a data source to a table location:

```
ln -s /mapr/my.cluster.com/user/
mapr/source_files/data.txt /mapr/
my.cluster.com/user/hive/warehouse/
ext_tbl_mh120/data_link.txt
```

3. Create an external Hive table in the ext_tbl_symlink directory (created in step 1):

```
CREATE EXTERNAL TABLE
file_link_table (...) ROW FORMAT
DELIMITED FIELDS TERMINATED BY ","
STORED AS TEXTFILE LOCATION '/user/
hive/warehouse/ext_tbl_symlink';
```

The Hive table has a symbolically linked text file as the data source. Data can be processed as if it is a regular data file.

Configuring Symlinks Support

When you have many small files and you are using symlinks, the performance of Hive operations are slower.

To enable or disable the symlink support, configure the `hive.sym.link.support.enabled` property in `hive-site.xml` file.

```
<property>

<name>hive.sym.link.support.enabled</name>
  <value>false</value>
  <description>Enables or disables
symlink support in Hive. Enabling
this functionality leads to
verification of each files and
folders to be a symlink which results
in slower performance when there
are many small files to process.</description>
</property>
```

The value of this property is set to `false` by default. To enable the symlink support, set the value to `true` and restart Hive services.

Hive 3.1.3 API Changes

This topic describes the public API changes that occurred between Hive 2.3.9 EEP 8.1.0 and Hive 3.1.3 EEP 9.0.0.

For more information, see [Hive 3.1.3.0 - 2210 \(EEP 9.0.0\) Release Notes](#) on page 7996.

JDBC Classes API Changes

This section contains changes made to classes related to the JDBC API in Hive.

Class `org.apache.hive.jdbc.HiveConnection` The following table lists the added methods for Hive.

Method	Description
<code>List<JdbcConnectionParams> getAllUrls(String zookeeperBasedHSUrl)</code>	Get all direct HiveServer2 URLs from a ZooKeeper based HiveServer2 URL .

Class `org.apache.hive.jdbc.HiveStatement` No changes.

Class `org.apache.hive.jdbc.Utils` The following table lists the added methods for Hive.

Method	Description
<code>public JdbcConnectionParams(JdbcConnectionParams params) {</code>	Constructor: based on connection parameters.

<pre>public static String getCanonicalHostName(String hostName)</pre>	<p>Method to get canonicalized hostname, given a hostname (possibly a CNAME).</p> <ul style="list-style-type: none"> Allows service-principals to use simplified CNAMEs. @param hostName: The hostname to be canonicalized. @return: Given a CNAME, the canonicalized hostname is returned. If not found, the original hostname is returned.
<pre>static void configureConnParams FromZooKeeper(JdbcC onnectionParams connParams)</pre>	<p>To configure using ZooKeeper.</p>

Security-related API Changes:

None.

NOTE:

- All API functionality changes are compatible with previous versions.
- For migration from ACID (transactional) tables in Hive 2.x to ACID (transactional) tables in Hive 3.x. separate document.
- To learn about known issues related to Hive-3.1.3 database configuration, Data Fabric SASL connection from edge nodes, HPE Data Fabric Object Store data processing with Hive-3.1.3, see [Hive 3.1.3.0 - 2210 \(EEP 9.0.0\) Release Notes](#) on page 7996.

Hive 2.3 API Changes

This topic describes the public API changes that occurred between Hive 2.1 EEP 5.0.0 and Hive 2.3 EEP 6.0.0.

For more information, see [Hive Release Notes](#) on page 7962.

JDBC classes API changes

This section contains changes made to classes related to the JDBC API in Hive.

Table

Method	Description
<code>List<String> parseInitFile(String initFile)</code>	Parses initial SQL file skipping comments that starts with # or --.

Table

Method	Description
<code>void setInPlaceUpdateStream(InPlaceUpdate stream)</code>	Only used by the beeline client to set the stream on which in place progress updates are to be shown.

Table

Method	Description
<code>JdbcConnectionParams parseURL(String uri)</code>	<p>Parse JDBC connection URL The new format of the URL is:</p> <pre>jdbc:hive2://:./dbName;sess_var_list? hive_conf_list#hive_var_list</pre> <p>where the optional sess, conf, and var lists are semicolon separated = pairs. For utilizing dynamic service discovery with HiveServer2, multiple comma-separated host:port pairs can be specified as shown above. The JDBC driver resolves the list of URIs and picks a specific server instance to connect to. Currently, dynamic service discovery using ZooKeeper is supported, in which case the host:port pairs represent a ZooKeeper ensemble. As before, if the host/port is not specified, it the driver runs an embedded Hive:</p> <ul style="list-style-type: none"> <code>jdbc:hive2://ubuntu:11000/db2?hive.cli.conf.printhead=true;hive.exec.mode.local.auto.inputbytes.max=9999#stab=salesTable;icol=customerID</code> <code>jdbc:hive2://?hive.cli.conf.printhead=true;hive.exec.mode.local.auto.inputbytes.max=9999#stab=salesTable;icol=customerID</code> <code>jdbc:hive2://ubuntu:11000/db2;user=foo;password=bar</code> <p>Connect to <code>http://server:10001/hs2</code>, with specified basicAuth credentials and initial database:</p> <pre>jdbc:hive2://server:10001/ db;user=foo;password=bar? hive.server2.transport.mode= http;hive.server2.thrift.http.path=hs2</pre>

Security-related API changes

The following properties are removed from the default `hive-site.xml` configuration on a secured cluster:

Table

Property	Value
<code>hive.server2.webui.keystore.path</code>	<code>/opt/mapr/conf/ssl_keystore.</code>
<code>hive.server2.webui.keystore.password</code>	Default keystore password.

The following property is added to the default `hive-site.xml` configuration on a secured cluster:

Table

Method	Description
hive.server2.use.SSL true	true

Since the HiveServer2 server is configured to use SSL encryption by default starting from Hive-2.3 EEP-6.0.0, add `ssl=true;` to a JDBC connection string when PAM or MAPR-SASL authentication is used.

For example:

Old JDBC connection string with PAM authentication:

```
beeline> !connect jdbc:hive2://<host>:10000/default;
```

New JDBC connection string with PAM authentication:

```
beeline> !connect jdbc:hive2://<host>:10000/default;ssl=true;
```

NOTE: All API functionality changes are compatible with previous versions.

Hive 2.1 API

This section contains the following:

New Classes in Hive 2.1

Hive 2.1 includes the following new classes:

Class	Description
org.apache.hadoop.hive.common. DiskRangeInfo	Contains disk range information including disk ranges and total length.
org.apache.hadoop.hive.common. JvmPauseMonitor	This is based on the JvmPauseMonitor from Hadoop.
org.apache.hadoop.hive.common. StringableMap	A utility class that can convert a HashMap of Properties into a colon separated string, and can take the same format of string and convert it to a HashMap of Properties.
org.apache.hadoop.hive.common. ValidCompactorTxnList	An implementation of org.apache.hadoop.hive.common.ValidTxnList for use by the compactor.
org.apache.hadoop.hive.common.io. DiskRange	The sections of a file.
org.apache.hadoop.hive.common.io. DiskRangeList	Alternative for Java linked list iterator interface to support concurrent modifications of the same list by multiple iterators.
org.apache.hadoop.hive.common.jsonexplain.tez. Printer	Creation of output string to show JSON plan.
org.apache.hadoop.hive.common.jsonexplain.tez. TezJsonParserUtils	JsonParser for Tez that prints a JSONObject into outputStream.

Class	Description
org.apache.hadoop.hive.common.metrics. LegacyMetrics	<p>The Metrics Subsystem allows exposure of a number of named parameters/counters via JMX, is intended to be used as a static subsystem, and has a couple of primary ways in which it can be used:</p> <ul style="list-style-type: none"> Using the set and get methods to set and get named parameters. Using the incrementCounter method to increment and set named parameters in one go, rather than having to make a get and then a set. Using the startScope and endScope methods to start and end named "scopes" that record the number of times they have been instantiated and amount of time (in milliseconds) spent inside the scopes.
org.apache.hadoop.hive.common.type. RandomTypeUtil	Creates random data of different object types.
org.apache.hadoop.hive.conf. VariableSubstitution	Substitution of environment variables.
org.apache.hadoop.hive.contrib.genericudf.example. GenericUDFAdd10	Initializes the GenericUDF (once per instance), evaluates the GenericUDF with the arguments, and gets the string to display.
org.apache.hadoop.hive.io. HdfsUtils	Utils to resolve file properties in MAPR filesystem.
org.apache.hadoop.hive.metastore. AcidEventListener	It handles cleanup of dropped partition/table/database in ACID related metastore tables.
org.apache.hadoop.hive.metastore. FileMetadataHandler	The base implementation of a file metadata handler for a specific file type.
org.apache.hadoop.hive.metastore. FileMetadataManager	Handle storage functions of metadata.
org.apache.hadoop.hive.metastore. HMSMetricsListener	Report metrics of metadata added and deleted by this Hive Metastore.
org.apache.hadoop.hive.metastore. Metastore	Class to arrange work with Metastore.
org.apache.hadoop.hive.metastore. PartFilterExprUtil	Utility functions for working with partition filter expressions.
org.apache.hadoop.hive.metastore.api. AbortTxnsRequest	Class for handling transactions request.
org.apache.hadoop.hive.metastore.api. AddForeignKeyRequest	Class for handling foreign key request.
org.apache.hadoop.hive.metastore.api. AddPrimaryKeyRequest	Class for handling primary key request.
org.apache.hadoop.hive.metastore.api. CacheFileMetadataRequest	Class for caching metadata requests.
org.apache.hadoop.hive.metastore.api. CacheFileMetadataResult	Class for caching metadata results.
org.apache.hadoop.hive.metastore.api. ClearFileMetadataResult	Class for clearing metadata results.
org.apache.hadoop.hive.metastore.api. DropConstraintRequest	Class for dropping constraint requests.
org.apache.hadoop.hive.metastore.api. ForeignKeysRequest	Class for handling foreign key requests.

Class	Description
org.apache.hadoop.hive.metastore.api. ForeignKeysResponse	Class for getting response from all functions.
org.apache.hadoop.hive.metastore.api. GetAllFunctionsResponse	Class for getting response from all functions.
org.apache.hadoop.hive.metastore.api. GetFileMetadataByExprRequest	Class for getting metadata from expression response.
org.apache.hadoop.hive.metastore.api. GetFileMetadataByExprResult	Class for getting metadata from expression result.
org.apache.hadoop.hive.metastore.api. MetadataPpdResult	Class for describing metadata rpd result.
org.apache.hadoop.hive.metastore.api. PrimaryKeysRequest	Class for describing primary key result.
org.apache.hadoop.hive.metastore.api. PrimaryKeysResponse	Class for describing primary key response.
org.apache.hadoop.hive.metastore.api. PutFileMetadataRequest	Class for output metadata request to file.
org.apache.hadoop.hive.metastore.api. PutFileMetadataResult	Class for output metadata result to file.
org.apache.hadoop.hive.metastore.api. SQLForeignKey	Class for describing SQL foreign key.
org.apache.hadoop.hive.metastore.api. SQLPrimaryKey	Class for describing SQL primary key.
org.apache.hadoop.hive.metastore.api. TableMeta	Class for describing table metadata.
org.apache.hadoop.hive.metastore.model. MConstraint	Model of constraints stored in metastore.
org.apache.hadoop.hive.metastore.txn. TxnUtils	Class for handling transactions.
org.apache.hadoop.hive ql. CompilationOpContext	Contains the operator sequence ID and a subset of compilation context that is passed to operators to get rid of some globals.
org.apache.hadoop.hive ql. QueryDisplay	Contains limited query information to save for WebUI. The class is synchronized, as WebUI may access information about a running query.
org.apache.hadoop.hive ql. QueryState	The class to store query level info such as queryId.
org.apache.hadoop.hive ql.exec. AbstractMapOperator	Abstract Map operator.
org.apache.hadoop.hive ql.exec. GlobalWorkMapFactory	Get job that has been executed on cluster as a map value.
org.apache.hadoop.hive ql.exec. ObjectCacheWrapper	Wrapping class for ObjectCache class.
org.apache.hadoop.hive ql.exec. SerializationUtilities	Utilities related to serialization and deserialization.
org.apache.hadoop.hive ql.exec. UDFClassLoader	UDFClassLoader is used to dynamically register udf (and related) jars. This was introduced to fix HIVE-11878. Each session will have its own instance of UDFClassLoader to support HiveServer2, which can contain multiple active sessions.
org.apache.hadoop.hive ql.exec.spark. CacheTran	Class for making cache persistent.
org.apache.hadoop.hive ql.exec.spark. SmallTableCache	Class for cache cleaning if new query is present.
org.apache.hadoop.hive ql.exec.spark. SparkDynamicPartitionPruner	The spark version of DynamicPartitionPruner.

Class	Description
org.apache.hadoop.hive ql.exec.spark.status.impl. SparkJobUtils	Utilities for spark job.
org.apache.hadoop.hive ql.exec.tez. ColumnarSplitSizeEstimator	Split size estimator for columnar file formats.
org.apache.hadoop.hive ql.exec.tez. HostAffinitySplitLocationProvider	This maps a split (path + offset) to an index based on the number of locations provided.
org.apache.hadoop.hive ql.exec.tez. InPlaceUpdates	Class responsible for inplace updates.
org.apache.hadoop.hive ql.exec.tez. KeyValuesFromKeyValue	Provides a key/values (note the plural values) interface out of a KeyValueReader, needed by ReduceRecordSource when reading input from a key/value source.
org.apache.hadoop.hive ql.exec.tez. KeyValuesFromKeyValues	Provides a key/values interface out of a KeyValuesReader for use by ReduceRecordSource.
org.apache.hadoop.hive ql.exec.tez. LlapObjectCache	Llap implementation for the shared object cache.
org.apache.hadoop.hive ql.exec.tez. Utils	Utilities for running tez jobs.
org.apache.hadoop.hive ql.exec.vector. IntervalDayTimeColumnVector	This class represents a nullable interval day time column vector capable of handling a wide range of interval day time values.
org.apache.hadoop.hive ql.exec.vector. ListColumnVector	The representation of a vectorized column of list objects.
org.apache.hadoop.hive ql.exec.vector. MapColumnVector	The representation of a vectorized column of map objects.
org.apache.hadoop.hive ql.exec.vector. MultiValuedColumnVector	The representation of a vectorized column of multi-valued objects, such as lists and maps.
org.apache.hadoop.hive ql.exec.vector. StructColumnVector	The representation of a vectorized column of struct objects.
org.apache.hadoop.hive ql.exec.vector. TimestampColumnVector	This class represents a nullable timestamp column vector capable of handling a wide range of timestamp values.
org.apache.hadoop.hive ql.exec.vector. UnionColumnVector	The representation of a vectorized column of struct objects.
org.apache.hadoop.hive ql.exec.vector. VectorSparkHashTableSinkOperator	Vectorized version of SparkHashTableSinkOperator. It delegates all the work to super class Copied from VectorFileSinkOperator.
org.apache.hadoop.hive ql.exec.vector. VectorSparkPartitionPruningSinkOperator	Vectorized version for SparkPartitionPruningSinkOperator.
org.apache.hadoop.hive ql.exec.vector.expressions. BRoundWithNumDigitsDoubleToDouble	Banking rounding implementation.
org.apache.hadoop.hive ql.exec.vector.expressions. CastDoubleToTimestamp	Cast double type to timestamp type.
org.apache.hadoop.hive ql.exec.vector.expressions. CastLongToTimestamp	Cast long type to timestamp type.
org.apache.hadoop.hive ql.exec.vector.expressions. CastMillisecondsLongToTimestamp	Cast milliseconds long type to timestamp.
org.apache.hadoop.hive ql.exec.vector.expressions. CastStringGroupToString	Cast string group type to string type.
org.apache.hadoop.hive ql.exec.vector.expressions. CastTimestampToBoolean	Cast timestamp type to boolean.

Class	Description
org.apache.hadoop.hive.ql.exec.vector.expressions. CastTimestampToDate	Cast timestamp type to decimal type.
org.apache.hadoop.hive.ql.exec.vector.expressions. CastTimestampToDouble	Cast timestamp type to double type.
org.apache.hadoop.hive.ql.exec.vector.expressions. CastTimestampToLong	Cast timestamp type to long type.
org.apache.hadoop.hive.ql.exec.vector.expressions. DateColSubtractDateColumn	Subtract two variables of date type.
org.apache.hadoop.hive.ql.exec.vector.expressions. DateColSubtractDateScalar	Subtract two variables of date type.
org.apache.hadoop.hive.ql.exec.vector.expressions. DateScalarSubtractDateColumn	Subtract two variables of date type.
org.apache.hadoop.hive.ql.exec.vector.expressions. FilterStructColumnInList	Evaluates an IN filter on a batch for a vector of structs.
org.apache.hadoop.hive.ql.exec.vector.expressions. FilterTimestampColumnInList	Evaluates IN filter on a batch for a vector of timestamps.
org.apache.hadoop.hive.ql.exec.vector.expressions. FuncBRoundWithNumDigitsDecimalToDecimal	Banking rounding for decimal digits.
org.apache.hadoop.hive.ql.exec.vector.expressions. FuncDecimalToTimestamp	This is a superclass for unary decimal functions and expressions returning timestamps that operate directly on the input and set the output.
org.apache.hadoop.hive.ql.exec.vector.expressions. FuncTimestampToDecimal	This is a superclass for unary timestamp functions and expressions returning decimals that operate directly on the input and set the output.
org.apache.hadoop.hive.ql.exec.vector.expressions. FuncTimestampToLong	This is a superclass for unary timestamp functions and expressions returning long that operate directly on the input and set the output.
org.apache.hadoop.hive.ql.exec.vector.expressions. IfExprDoubleColumnDoubleColumn	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions. IfExprIntervalDayTimeColumnColumn	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions. IfExprIntervalDayTimeColumnScalar	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions. IfExprIntervalDayTimeScalarColumn	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions. IfExprIntervalDayTimeScalarScalar	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions. IfExprLongColumnLongColumn	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions. IfExprTimestampColumnColumn	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions. IfExprTimestampColumnColumnBase	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions. IfExprTimestampColumnScalar	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions. IfExprTimestampColumnScalarBase	Computes IF(expr1, expr2, expr3) for 3 input column expressions.

Class	Description
org.apache.hadoop.hive ql.exec.vector.expressions.IfExprTimestampScalarColumn	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive ql.exec.vector.expressions.IfExprTimestampScalarColumnBase	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive ql.exec.vector.expressions.IfExprTimestampScalarScalar	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive ql.exec.vector.expressions.IfExprTimestampScalarScalarBase	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive ql.exec.vector.expressions.LongColEqualLongColumn	If equal two columns as vectors.
org.apache.hadoop.hive ql.exec.vector.expressions.LongColEqualLongScalar	If equal long column and long scalar as vectors.
org.apache.hadoop.hive ql.exec.vector.expressions.LongColGreaterEqualLongColumn	If greater or equal two columns as vectors.
org.apache.hadoop.hive ql.exec.vector.expressions.LongColGreaterEqualLongScalar	If greater or equal long column and long scalar.
org.apache.hadoop.hive ql.exec.vector.expressions.LongColGreaterLongColumn	If greater two columns as vectors.
org.apache.hadoop.hive ql.exec.vector.expressions.LongColGreaterLongScalar	If greater long column and long scalar as vectors.
org.apache.hadoop.hive ql.exec.vector.expressions.LongColLessEqualLongColumn	If less equal two columns as vectors.
org.apache.hadoop.hive ql.exec.vector.expressions.LongColLessEqualLongScalar	If less equal long column and long scalar as vectors.
org.apache.hadoop.hive ql.exec.vector.expressions.LongColLessLongColumn	If less two columns as vectors.
org.apache.hadoop.hive ql.exec.vector.expressions.LongColLessLongScalar	If less long column and long scalar as vectors.
org.apache.hadoop.hive ql.exec.vector.expressions.LongColNotEqualLongColumn	If not equal two columns as vectors.
org.apache.hadoop.hive ql.exec.vector.expressions.LongColNotEqualLongScalar	If not equal long column and long scalar as vectors.
org.apache.hadoop.hive ql.exec.vector.expressions.LongScalarEqualLongColumn	If equal long scalar and long column.
org.apache.hadoop.hive ql.exec.vector.expressions.LongScalarGreaterEqualLongColumn	If greater equal long scalar and long column as vector.
org.apache.hadoop.hive ql.exec.vector.expressions.LongScalarGreaterLongColumn	If greater long scalar and long column as vectors.
org.apache.hadoop.hive ql.exec.vector.expressions.LongScalarLessEqualLongColumn	If less equal long scalar and long column as vector.
org.apache.hadoop.hive ql.exec.vector.expressions.LongScalarLessLongColumn	If less long scalar and long column as vectors.
org.apache.hadoop.hive ql.exec.vector.expressions.LongScalarNotEqualLongColumn	If not equal long scalar and long column as vectors.
org.apache.hadoop.hive ql.exec.vector.expressions.SelectStringColLikeStringScalar	Select like statement for string column and string scalar.

Class	Description
org.apache.hadoop.hive.ql.exec.vector.expressions. StructColumnInList	Evaluates an IN boolean expression (not a filter) on a batch for a vector of structs.
org.apache.hadoop.hive.ql.exec.vector.expressions. TimestampColumnInList	Returns a boolean value indicating if a column is IN a list of constants.
org.apache.hadoop.hive.ql.exec.vector.expressions. TimestampToStringUnaryUDF	This is a superclass for unary long functions returning strings that operate directly on the input and set the output.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFDateTimestamp	Vectorized version of TO_DATE(timestamp).
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFDayOfMonthDate	Expression to get day of month.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFDayOfMonthTimestamp	Expression to get day of month.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFHourDate	Returns hour of day.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFHourTimestamp	Returns hour of day.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFMinuteDate	Returns minute value.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFMinuteTimestamp	Returns minute value.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFMonthDate	Returns month value.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFMonthTimestamp	Returns month value.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFSecondDate	Expression to get seconds.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFSecondTimestamp	Expression to get seconds.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFTimestampFieldDate	Abstract class to return various fields from a Timestamp or Date.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFTimestampFieldTimestamp	Abstract class to return various fields from a Timestamp.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFUnixTimeStampDate	Returns Unix Timestamp.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFUnixTimeStampTimestamp	Returns Unix Timestamp.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFWeekOfYearDate	Expression to get week of year.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFWeekOfYearTimestamp	Expression to get week of year.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFYearDate	Expression to get year as a long.
org.apache.hadoop.hive.ql.exec.vector.expressions. VectorUDFYearTimestamp	Expression to get year as a long.

Class	Description
org.apache.hadoop.hive.ql.exec.vector.expressions.agggregates. VectorUDAFAvgTimestamp	Generated from template VectorUDAFAvg.txt.
org.apache.hadoop.hive.ql.exec.vector.expressions.agggregates. VectorUDAFStdPopTimestamp	Vectorized implementation for VARIANCE aggregates.
org.apache.hadoop.hive.ql.exec.vector.expressions.agggregates. VectorUDAFStdSampTimestamp	Vectorized implementation for VARIANCE aggregates.
org.apache.hadoop.hive.ql.exec.vector.expressions.agggregates. VectorUDAFVarPopTimestamp	Vectorized implementation for VARIANCE aggregates.
org.apache.hadoop.hive.ql.exec.vector.expressions.agggregates. VectorUDAFVarSampTimestamp	Vectorized implementation for VARIANCE aggregates.
org.apache.hadoop.hive.ql.hooks. LineageLogger	Implementation of a post execute hook that logs lineage info to a log file.
org.apache.hadoop.hive.ql.hooks. PostExecOrcFileDump	Post execution hook to print orc file dump for files that will be read by fetch task.
org.apache.hadoop.hive.ql.hooks. PostExecTezSummaryPrinter	Post execution hook to print hive tez counters to console error stream.
org.apache.hadoop.hive.ql.io. HdfsUtils	Utilities for hadoop fs.
org.apache.hadoop.hive.ql.io. IOContextMap	Uses the global static map of IOContext-s inside IOContext, uses threadlocal for Spark, and creates inheritable threadlocal with attemptId (only set in LLAP), which will propagate to all the Tez threads.
org.apache.hadoop.hive.ql.io. NullScanFileSystem	Filesystem that does not allow Hive to read files for nullscans.
org.apache.hadoop.hive.ql.io. ProxyLocalFileSystem	This class is to workaround existing issues on LocalFileSystem.
org.apache.hadoop.hive.ql.io. SyntheticFileId	Create synthetic ID for file.
org.apache.hadoop.hive.ql.io.orc. ExternalCache	Metastore-based footer cache storing serialized footers.
org.apache.hadoop.hive.ql.io.orc. MetastoreExternalCachesByConf	An implementation of external cache and factory based on metastore.
org.apache.hadoop.hive.ql.io.orc. OrcFileFormatProxy	File format proxy for ORC.
org.apache.hadoop.hive.ql.io.orc. RecordReaderImpl	Implementation of record reader.
org.apache.hadoop.hive.ql.io.parquet.read. ParquetFilterPredicateConverter	Translate the search argument to the filter predicate parquet uses.
org.apache.hadoop.hive.ql.io.sarg. ConvertAstToSearchArg	Converting asterisk and use it as a search argument.
org.apache.hadoop.hive.ql.io.sarg. SearchArgumentImpl	The implementation of SearchArguments.
org.apache.hadoop.hive.ql.lib. PreOrderOnceWalker	This class takes list of starting nodes and walks them in pre-order.
org.apache.hadoop.hive.ql.log. HiveEventCounter	A log4J2 appender that simply counts logging events in four levels: fatal, error, warn, and info.
org.apache.hadoop.hive.ql.log. NoDeleteRollingFileAppender	Instantiate a RollingFileAppender and open the file designated by filename. The opened filename will become the output destination for this appender.
org.apache.hadoop.hive.ql.log. NullAppender	A NullAppender that never outputs a message to any device.

Class	Description
org.apache.hadoop.hive.ql.log.PidFilePatternConverter	FilePattern converter that converts %pid pattern to @ information obtained at runtime.
org.apache.hadoop.hive.ql.metadata.ForeignKeyInfo	ForeignKeyInfo is a metadata structure containing the foreign keys associated with a table.
org.apache.hadoop.hive.ql.metadata.PrimaryKeyInfo	PrimaryKeyInfo is a metadata structure containing the primary key associated with a table.
org.apache.hadoop.hive.ql.metadata.TableIterable	Gets Table objects for a table list.
org.apache.hadoop.hive.ql.optimizer.OperatorComparatorFactory	Comparator for table operators.
org.apache.hadoop.hive.ql.optimizer.PartitionColumnsSelector	Takes a Filter expression, and if its predicate contains an IN operator whose children are constant structs or structs containing constant fields, it will try to generate predicate with IN clauses containing only partition columns.
org.apache.hadoop.hive.ql.optimizer.PointLookupOptimizer	Takes a Filter expression, and if its predicate contains an OR operator whose children are constant equality expressions, it will try to generate an IN clause (which is more efficient).
org.apache.hadoop.hive.ql.optimizer.RedundantDynamicPruningConditionsRemoval	Takes a Filter operator on top of a TableScan and removes dynamic pruning conditions if static partition pruning has been triggered already.
org.apache.hadoop.hive.ql.optimizer.SparkRemoveDynamicPruningBySize	Disables pruning if the number of keys for dynamic pruning is too large.
org.apache.hadoop.hive.ql.optimizer.calcite.HivePlannerContext	Creating context for Hive Planner.
org.apache.hadoop.hive.ql.optimizer.calcite.HiveRelBuilder	Builder for relational expressions in Hive.
org.apache.hadoop.hive.ql.optimizer.calcite.HiveRelFactories	Factory class for creating relational operators for queries.
org.apache.hadoop.hive.ql.optimizer.calcite.HiveRexExecutorImpl	Hive registry executor implementation.
org.apache.hadoop.hive.ql.optimizer.calcite.HiveRexUtil	Utilities for hive registry executor.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveBetween	Operand type-inference strategy where an unknown operand type is derived from the first operand with a known type, but the first operand is a boolean.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveIn	Create in clause instance for hive queries.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveMultiJoin	A HiveMultiJoin represents a succession of binary joins.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveSortLimit	Sorting limit in hive queries.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveAggregateJoinTransposeRule	Planner rule that pushes an org.apache.calcite.rel.core.Aggregate past a org.apache.calcite.rel.core.Join.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveAggregateProjectMergeRule	Planner rule that recognizes a HiveAggregate on top of a HiveProject and if possible, aggregates through the project or removes the project.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveAggregatePullUpConstantsRule	Rule for pull up constants aggregation.

Class	Description
org.apache.hadoop.hive.ql.optimizer.calcite.rules. HiveFilterAggregateTransposeRule	Transpose rule for filter aggregation.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. HiveFilterProjectTSTransposeRule	Transpose rule for filtering project TST.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. HiveFilterSortTransposeRule	Transpose rule for filtering sort.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. HiveJoinProjectTransposeRule	Transpose rule for join project.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. HiveJoinLookupOptimizerRule	Takes a Filter expression, and if its predicate contains an OR operator whose children are constant equality expressions, tries to generate an IN clause (which is more efficient).
org.apache.hadoop.hive.ql.optimizer.calcite.rules. HiveProjectFilterPullUpConstantsRule	Planner rule that infers constant expressions from Filter into a Project operator.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. HiveProjectSortTransposeRule	Transpose rule for project sort.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. HiveReduceExpressionsRule	Collection of planner rules that apply various simplifying transformations on RexNode trees.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. HiveReduceExpressionsWithStatsRule	This rule simplifies the condition in Filter operators using the column statistics (if available).
org.apache.hadoop.hive.ql.optimizer.calcite.rules. HiveRelColumnsAlignment	Infers the order in Aggregate columns and the order of conjuncts in a Join condition that might be more beneficial to avoid additional sort stages.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. HiveSortJoinReduceRule	Planner rule that pushes a org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveSortLimit past a org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveJoin.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. HiveSortLimitPullUpConstantsRule	Planner rule that pulls up constant keys through a SortLimit operator.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. HiveSortMergeRule	This rule will merge two HiveSortLimit operators.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. HiveSortProjectTransposeRule	Transpose rule for sort project.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. HiveSortRemoveRule	Planner rule that removes a org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveSortLimit.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. HiveSortUnionReduceRule	Planner rule that pushes a org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveSortLimit past a org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveUnion.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. HiveUnionPullUpConstantsRule	Planner rule that pulls up constants through a Union operator.
org.apache.hadoop.hive.ql.optimizer.calcite.stats. HiveRelMdPredicates	Infers predicates for a project.
org.apache.hadoop.hive.ql.optimizer.physical. LlapDecider	LlapDecider takes care of tagging certain vertices in the execution graph as "llap", which in turn causes them to be submitted to an llap daemon instead of a regular yarn container.

Class	Description
org.apache.hadoop.hive.ql.optimizer.physical. MemoryDecider	MemoryDecider is a simple physical optimizer that adjusts the memory layout of tez tasks.
org.apache.hadoop.hive.ql.optimizer.physical. SerializeFilter	SerializeFilter is a simple physical optimizer that serializes all filter expressions in Tablescan Operators.
org.apache.hadoop.hive.ql.optimizer.spark. CombineEquivalentWorkResolver	CombineEquivalentWorkResolver searches inside SparkWork, finds and combines equivalent works.
org.apache.hadoop.hive.ql.optimizer.spark. SparkPartitionPruningSinkDesc	Description of spark partition pruning sink.
org.apache.hadoop.hive.ql.parse. AnalyzeCommandUtils	Utilities for command analysis.
org.apache.hadoop.hive.ql.parse. ColumnStatsAutoGatherContext	ColumnStatsAutoGatherContext is passed to the compiler when set hive.stats.autogather is true during the INSERT OVERWRITE command.
org.apache.hadoop.hive.ql.parse. MaskAndFilterInfo	Information for masking and filtering.
org.apache.hadoop.hive.ql.parse. TableMask	The main purpose for this class is for authorization.
org.apache.hadoop.hive.ql.parse.spark. SparkPartitionPruningSinkOperator	This operator gets partition info from the upstream operators and writes them to HDFS.
org.apache.hadoop.hive.ql.parse.spark. SplitOpTreeForDPP	This processor triggers on SparkPartitionPruningSinkOperator.
org.apache.hadoop.hive.ql.plan. AbortTxnsDesc	Descriptor for aborting transactions.
org.apache.hadoop.hive.ql.plan. CacheMetadataDesc	Description for metadata cache.
org.apache.hadoop.hive.ql.plan. ShowCreateDatabaseDesc	Shows the name of the database.
org.apache.hadoop.hive.ql.plan. VectorPartitionConversion	PartitionConversion.
org.apache.hadoop.hive.ql.plan. VectorPartitionDesc	VectorMapDesc.
org.apache.hadoop.hive.ql.plan. VectorReduceSinkDesc	VectorReduceSinkDesc.
org.apache.hadoop.hive.ql.plan. VectorReduceSinkInfo	VectorGroupByAggregationInfo.
org.apache.hadoop.hive.ql.ppd. SimplePredicatePushDown	Implementation of predicate push down.
org.apache.hadoop.hive.ql.security.authorization. DefaultHiveAuthorizationTranslator	Default implementation of HiveAuthorizationTranslator.
org.apache.hadoop.hive.ql.security.authorization.plugin. AbstractHiveAuthorizer	Abstract class that extends HiveAuthorizer.
org.apache.hadoop.hive.ql.session. ClearDanglingScratchDir	A tool to remove dangling scratch directory.
org.apache.hadoop.hive.ql.stats. StatsCollectionContext	Creating context for stats collection.
org.apache.hadoop.hive.ql.txn.compactor. HouseKeeperServiceBase	Housekeeper for running services.
org.apache.hadoop.hive.ql.udf. UDFChr	UDFChr converts an integer into its ASCII equivalent.
org.apache.hadoop.hive.ql.udf. UDFCrc32	UDFCrc32.
org.apache.hadoop.hive.ql.udf. UDFMd5	UDFMd5.
org.apache.hadoop.hive.ql.udf. UDFReplace	UDFReplace replaces all substrings that are matched with a replacement substring.

Class	Description
org.apache.hadoop.hive ql.udf.UDFSha1	UDFSha.
org.apache.hadoop.hive ql.udf.UDFVersion	UDFVersion
org.apache.hadoop.hive ql.udf.generic.BaseMaskUDF	User defined function for masking.
org.apache.hadoop.hive ql.udf.generic.GenericUDAFSumEmptyIsZero	User defined aggregation function for summing empty as zeros.
org.apache.hadoop.hive ql.udf.generic.GenericUDFAesBase	Base for user defined functions.
org.apache.hadoop.hive ql.udf.generic.GenericUDFAesDecrypt	User defined function for decryption.
org.apache.hadoop.hive ql.udf.generic.GenericUDFAesEncrypt	User defined function for encryption.
org.apache.hadoop.hive ql.udf.generic.GenericUDFBRound	User defined function for banking rounding.
org.apache.hadoop.hive ql.udf.generic.GenericUDFBaseNWayCompare	Base class for comparison UDF's (Greatest and Least).
org.apache.hadoop.hive ql.udf.generic.GenericUDFMask	User defined function for masking.
org.apache.hadoop.hive ql.udf.generic.GenericUDFMaskFirstN	User defined function for masking first n symbols.
org.apache.hadoop.hive ql.udf.generic.GenericUDFMaskHash	User defined function that returns a hashed value based on str.
org.apache.hadoop.hive ql.udf.generic.GenericUDFMaskLastN	User defined function for masking last n symbols.
org.apache.hadoop.hive ql.udf.generic.GenericUDFMaskShowFirstN	User defined function for showing masked first n symbols.
org.apache.hadoop.hive ql.udf.generic.GenericUDFMaskShowLastN	User defined function for showing masked last n symbols.
org.apache.hadoop.hive ql.udf.generic.GenericUDFParamUtils	Generic UDF params utility class.
org.apache.hadoop.hive ql.udf.generic.GenericUDFQuarter	GenericUDFQuarter.
org.apache.hadoop.hive ql.udf.generic.GenericUDFRegex	UDF to extract a specific group identified by a java regex.
org.apache.hadoop.hive ql.udf.generic.GenericUDFSha2	GenericUDFSha2.
org.apache.hadoop.hive ql.udf.generic.GenericUDFSubstringIndex	GenericUDFSubstringIndex.
org.apache.hadoop.hive ql.udf.generic.GenericUDTFGetSplits	GenericUDTFGetSplits.
org.apache.hadoop.hive ql.util.DependencyResolver	Query dependency resolver.
org.apache.hadoop.hive ql.util.ResourceDownloader	Resource downloader.
org.apache.hadoop.hive ql.util.TimestampUtils	Utilities for Timestamps and the relevant conversions.
org.apache.hadoop.hive.serde2.DefaultFetchFormatter	Serializes row by user specified serde and calls toString() to make string type result.
org.apache.hadoop.hive.serde2.NoOpFetchFormatter	A No-op fetch formatter.

Class	Description
org.apache.hadoop.hive.serde2.binarysortable. BinarySortableSerDeWithEndPrefix	Serializer deserializer for binary sortable.
org.apache.hadoop.hive.serde2.thrift. ColumnBuffer	Column buffer.
org.apache.hadoop.hive.serde2.thrift. ThriftFormatter	Thrift formatter.
org.apache.hadoop.hive.serde2.thrift. ThriftJDBCBinarySerDe	Serializes the final output to thrift-able objects directly in the SerDe.
org.apache.hadoop.hive.thrift. HiveDelegationTokenManager	Delegation token manager.
org.apache.hive.beeline. ClientCommandHookFactory	Updates some client side information after executing some Hive commands.
org.apache.hive.beeline. ClientHook	This is the client's hook and used for new Hive CLI.
org.apache.hive.common.util. DateParser	Date parser class for Hive.
org.apache.hive.common.util. FixedSizeObjectPool	Simple object pool of limited size.
org.apache.hive.common.util. HashCodeUtil	Utilities for hash code.
org.apache.hive.common.util. IntervalDayTimeUtils	DateUtils.
org.apache.hive.hcatalog.streaming. AbstractRecordWriter	Class for defining record writer.
org.apache.hive.jdbc. HttpTokenAuthInterceptor	The class is instantiated with the username and password, it is then used to add header with these credentials to HTTP requests
org.apache.hive.jdbc. XsrfHttpRequestInterceptor	Http request interceptor for xsrf token.
org.apache.hive.service.cli.operation. GetCrossReferenceOperation	GetCrossReferenceOperation.
org.apache.hive.service.cli.operation. GetPrimaryKeysOperation	GetPrimaryKeysOperation.
org.apache.hive.service.cli.operation. SQLOperationDisplay	Used to display some info in the HS2 WebUI.
org.apache.hive.service.cli.operation. SQLOperationDisplayCache	Cache some SQLOperation information for WebUI
org.apache.hive.service.cli.thrift. RetryingThriftCLIServiceClient	RetryingThriftCLIServiceClient.

New Interfaces in Hive 2.1

Hive 2.1 includes the following new interfaces:

Interface	Description
org.apache.hadoop.hive.common. Pool	Simple object pool to prevent GC on small objects passed between threads.
org.apache.hadoop.hive.common.io. Allocator	An allocator provided externally to storage classes to allocate MemoryBuffer-s.
org.apache.hadoop.hive.common.io. DataCache	An abstract data cache that IO formats can use to retrieve and cache data.
org.apache.hadoop.hive.conf. HiveVariableSource	Getting hive variables.
org.apache.hadoop.hive.metastore. FileFormatProxy	Same as PartitionExpressionProxy, but for file format specific methods for metadata cache.

org.apache.hadoop.hive.metastore. HouseKeeperService	Runs arbitrary background logic inside the metastore service.
org.apache.hadoop.hive.metastore.txn. TxnStore	A handler to answer transaction related calls that come into the metastore server.
org.apache.hadoop.hive ql.exec.tez. KeyValuesAdapter	Key-values interface for the Reader used by ReduceRecordSource
org.apache.hadoop.hive ql.exec.vector.expressions. IStructInExpr	Interface used for both filter and non-filter versions of IN to simplify VectorizationContext code.
org.apache.hadoop.hive ql.exec.vector.expressions. ITimestampInExpr	Interface used to process timestamp in expression.
org.apache.hadoop.hive ql.io. ColumnarSplit	Interface when implemented should return the estimated size of columnar projections that will be read from the split.
org.apache.hadoop.hive ql.io. LlapAwareSplit	Split that is aware that it could be executed in LLAP.
org.apache.hadoop.hive ql.io. LlapWrappableInputFormatInterface	Marker interface for LLAP; serves no other purpose.
org.apache.hadoop.hive ql.io. SelfDescribingInputFormatInterface	Marker interface to indicate a given input format is self-describing and can perform schema evolution itself.
org.apache.hadoop.hive ql.io. StreamingOutputFormat	Marker interface for streaming output formats.
org.apache.hadoop.hive ql.security.authorization.plugin. HiveAuthorizationTranslator	This interface has functions that provide the ability to customize the translation from Hive internal representations of Authorization objects to the public API objects This is an interface that is not meant for general use, it is targeted to some specific use cases of Apache Sentry (incubating).
org.apache.hadoop.hive.serde2. FetchFormatter	(For internal-use only) Used in ListSinkOperator for formatting final output.

Changed Classes in Hive 2.1

The following classes have changes in Hive 2.1:

Class	Description
org.apache.hadoop.hive.accumulo.mr. HiveAccumuloTableOutputFormat	Output format for accumulo tables.
org.apache.hadoop.hive.cli. CliDriver	CliDriver.
org.apache.hadoop.hive.cli. OptionsProcessor	OptionsProcessor.
org.apache.hadoop.hive.common. CompressionUtils	Contains methods used for the purposes of compression. This class should not be accessed from code run in Hadoop.
org.apache.hadoop.hive.common. FileUtils	Collection of file manipulation utilities common across Hive.
org.apache.hadoop.hive.common. HiveStatsUtils	HiveStatsUtils.
org.apache.hadoop.hive.common. JavaUtils	Collection of Java class loading/reflection related utilities common across Hive.
org.apache.hadoop.hive.common. LogUtils	Utilities common to logging operations.
org.apache.hadoop.hive.common. ObjectPair	Creating pair out of templates.
org.apache.hadoop.hive.common. ServerUtils	ServerUtils (specific to HiveServer version 1)

Class	Description
org.apache.hadoop.hive.common. StatsSetupConst	Defines the constant strings used by the statistics implementation.
org.apache.hadoop.hive.common. ValidReadTxnList	An implementation of org.apache.hadoop.hive.common.ValidTxnList for use by readers.
org.apache.hadoop.hive.common.cli. CommonCliOptions	Reusable code for Hive Cli's.
org.apache.hadoop.hive.common.io. NonSyncByteArrayInputStream	A thread-not-safe version of ByteArrayOutputStream, which removes all synchronized modifiers.
org.apache.hadoop.hive.common.type. HiveDecimal	HiveDecimal.
org.apache.hadoop.hive.common.type. HiveIntervalDayTime	Day-time interval type representing an offset in days/hours/minutes/seconds, with nanosecond precision.
org.apache.hadoop.hive.common.type. HiveVarchar	HiveVarChar.
org.apache.hadoop.hive.conf. HiveConf	Hive Configuration.
org.apache.hadoop.hive.conf. HiveConfUtil	Hive Configuration utils
org.apache.hadoop.hive.contrib.serde2. MultiDelimitSerDe	This SerDe allows user to use multiple characters as the field delimiter for a table.
org.apache.hadoop.hive.contrib.serde2. RegexSerDe	RegexSerDe uses regular expression (regex) to serialize/deserialize.
org.apache.hadoop.hive.contrib.serde2. TypedBytesSerDe	TypedBytesSerDe uses typed bytes to serialize/deserialize.
org.apache.hadoop.hive.contrib.serde2.s3. S3LogDeserializer	S3LogDeserializer.
org.apache.hadoop.hive.hbase. AbstractHBaseKeyPredicateComposer	Simple abstract class to help with creation of a DecomposedPredicate.
org.apache.hadoop.hive.hbase. CompositeHBaseKeyFactory	Factory that creates composite keys.
org.apache.hadoop.hive.hbase. HBaseLazyObjectFactory	Replaces original keyOI with OI which is create by HBaseKeyFactory provided by serde property for hbase.
org.apache.hadoop.hive.hbase. HBaseSerDe	HBaseSerDe can be used to serialize object into an HBase table and deserialize objects from an HBase table.
org.apache.hadoop.hive.hbase. HBaseSerDeHelper	Helper class for HBaseSerDe
org.apache.hadoop.hive.hbase. HiveHBaseTableInputFormat	HiveHBaseTableInputFormat implements InputFormat for HBase storage handler tables, decorating an underlying HBase TableInputFormat with extra Hive logic such as column pruning and filter pushdown.
org.apache.hadoop.hive.hbase. HiveHBaseTableOutputFormat	HiveHBaseTableOutputFormat implements HiveOutputFormat for HBase tables.
org.apache.hadoop.hive.hbase. LazyHBaseCellMap	LazyHBaseCellMap refines LazyMap with HBase column mapping.
org.apache.hadoop.hive.hwi. HWIContextListener	After getting a contextInitialized event, this component starts an instance of the HiveSessionManager.
org.apache.hadoop.hive.hwi. HWIServer	This is the entry point for HWI.
org.apache.hadoop.hive.hwi. HWISessionItem	HWISessionItem can be viewed as a wrapper for a Hive shell.

Class	Description
org.apache.hadoop.hive.hwi. HWISessionManager	HiveSessionManager is a Runnable started inside a web application context.
org.apache.hadoop.hive.metastore. Deadline	Monitors long running methods in a thread.
org.apache.hadoop.hive.metastore. HiveAlterHandler	Hive specific implementation of alter.
org.apache.hadoop.hive.metastore. HiveMetaStore	Removes application logic to a separate interface.
org.apache.hadoop.hive.metastore. HiveMetaStoreClient	Hive Metastore Client.
org.apache.hadoop.hive.metastore. HiveMetaStoreFsImpl	Class to handle methods for filesystem and data related to metastore.
org.apache.hadoop.hive.metastore. LockComponentBuilder	A builder for LockComponents.
org.apache.hadoop.hive.metastore. LockRequestBuilder	Builder class to make constructing LockRequest easier.
org.apache.hadoop.hive.metastore. MetaStoreSchemaInfo	Information about metastore schemas stored in database.
org.apache.hadoop.hive.metastore. MetaStoreUtils	Utilities to handle metastore data.
org.apache.hadoop.hive.metastore. ObjectStore	Interface between the application logic and the database store that contains the objects.
org.apache.hadoop.hive.metastore. PartitionDropOptions	Generalizes the switches for dropPartitions().
org.apache.hadoop.hive.metastore. RetryingHMSHandler	Handler for hive metastore.
org.apache.hadoop.hive.metastore. RetryingMetaStoreClient	RetryingMetaStoreClient.
org.apache.hadoop.hive.metastore. StatObjectConverter	Contains conversion logic that creates Thrift stat objects from JDO stat objects and plain arrays from DirectSQL.
org.apache.hadoop.hive.metastore. Warehouse	Represents a warehouse where data of Hive tables is stored.
org.apache.hadoop.hive.metastore.api. AbortTxnRequest	Aborting transaction request.
org.apache.hadoop.hive.metastore.api. AddDynamicPartitions	Adding dynamic partitions.
org.apache.hadoop.hive.metastore.api. AddPartitionsRequest	Adding partition request.
org.apache.hadoop.hive.metastore.api. AddPartitionsResult	Adding partition result.
org.apache.hadoop.hive.metastore.api. AggrStats	Aggregation statistics.
org.apache.hadoop.hive.metastore.api. BinaryColumnStatsData	Binary column statistics data.
org.apache.hadoop.hive.metastore.api. BooleanColumnStatsData	Boolean column statistics data.
org.apache.hadoop.hive.metastore.api. CheckLockRequest	Checking request on acquiring lock.
org.apache.hadoop.hive.metastore.api. ColumnStatistics	Column statistics class.
org.apache.hadoop.hive.metastore.api. ColumnStatisticsDesc	Column statistics description.
org.apache.hadoop.hive.metastore.api. ColumnStatisticsObject	Column statistics object.

Class	Description
org.apache.hadoop.hive.metastore.api. CommitTxnRequest	Commit transaction request.
org.apache.hadoop.hive.metastore.api. CompactionRequest	Compaction request.
org.apache.hadoop.hive.metastore.api. CurrentNotificationEventId	Current notification event ID.
org.apache.hadoop.hive.metastore.api. Database	Class that describes database.
org.apache.hadoop.hive.metastore.api. Date	Date class.
org.apache.hadoop.hive.metastore.api. DateColumnStatsData	Date column statistics data.
org.apache.hadoop.hive.metastore.api. Decimal	Handling decimal type.
org.apache.hadoop.hive.metastore.api. DecimalColumnStatsData	Decimal column statistics data.
org.apache.hadoop.hive.metastore.api. DoubleColumnStatsData	Double column statistics data.
org.apache.hadoop.hive.metastore.api. DropPartitionsExpr	Drop partitions expression.
org.apache.hadoop.hive.metastore.api. DropPartitionsRequest	Drop partitions request.
org.apache.hadoop.hive.metastore.api. DropPartitionsResult	Drop partitions result.
org.apache.hadoop.hive.metastore.api. EnvironmentContext	Environment context structure.
org.apache.hadoop.hive.metastore.api. FieldSchema	Field schema structure.
org.apache.hadoop.hive.metastore.api. FireEventRequest	Fire event request.
org.apache.hadoop.hive.metastore.api. FireEventResponse	Fire event response.
org.apache.hadoop.hive.metastore.api. Function	Function structure.
org.apache.hadoop.hive.metastore.api. GetOpenTxnsInfoResponse	Getter for open transactions information about response.
org.apache.hadoop.hive.metastore.api. GetOpenTxnsResponse	Getter for open transactions response.
org.apache.hadoop.hive.metastore.api. GetPrincipalsInRoleRequest	Getting request for principals in role.
org.apache.hadoop.hive.metastore.api. GetPrincipalsInRoleResponse	Getting response for principals in role.
org.apache.hadoop.hive.metastore.api. GetRoleGrantsForPrincipalRequest	Getting request for granting role for principal.
org.apache.hadoop.hive.metastore.api. GetRoleGrantsForPrincipalResponse	Getting response for granting role for principal.
org.apache.hadoop.hive.metastore.api. GrantRevokePrivilegeRequest	Request for revoking granted privilege.
org.apache.hadoop.hive.metastore.api. GrantRevokePrivilegeResponse	Response for revoking granted privilege.

Class	Description
org.apache.hadoop.hive.metastore.api. GrantRevokeRoleRequest	Request for revoking granted role.
org.apache.hadoop.hive.metastore.api. GrantRevokeRoleResponse	Response for revoking granted role.
org.apache.hadoop.hive.metastore.api. HeartbeatRequest	Request for heartbeat.
org.apache.hadoop.hive.metastore.api. HeartbeatTxnRangeRequest	Request for transaction range request.
org.apache.hadoop.hive.metastore.api. HeartbeatTxnRangeResponse	Response for transaction range response.
org.apache.hadoop.hive.metastore.api. HiveObjectPrivilege	Description of privileges for hive object.
org.apache.hadoop.hive.metastore.api. HiveObjectRef	Hive object reference.
org.apache.hadoop.hive.metastore.api. Index	Description of index.
org.apache.hadoop.hive.metastore.api. InsertEventRequestData	Class to handle data about insert event on request.
org.apache.hadoop.hive.metastore.api. LockComponent	Description of lock component.
org.apache.hadoop.hive.metastore.api. LockRequest	Description of lock request.
org.apache.hadoop.hive.metastore.api. LockResponse	Description of lock response.
org.apache.hadoop.hive.metastore.api. LongColumnStatsData	Description of long column statistics data.
org.apache.hadoop.hive.metastore.api. NotificationEvent	Description of notification event.
org.apache.hadoop.hive.metastore.api. NotificationEventRequest	Description of notification event on request.
org.apache.hadoop.hive.metastore.api. NotificationEventResponse	Description of notification event on response.
org.apache.hadoop.hive.metastore.api. OpenTxnRequest	Description of open transactions on request.
org.apache.hadoop.hive.metastore.api. OpenTxnsResponse	Description of open transactions on response.
org.apache.hadoop.hive.metastore.api. Order	Description of order.
org.apache.hadoop.hive.metastore.api. Partition	Description of partition.
org.apache.hadoop.hive.metastore.api. PartitionListComposingSpec	Description of partition list composing specification.
org.apache.hadoop.hive.metastore.api. PartitionSpec	Description of partition specification.
org.apache.hadoop.hive.metastore.api. PartitionSpecWithSharedSD	Description of partition specification with shared sd.
org.apache.hadoop.hive.metastore.api. PartitionWithoutSD	Description of partition without sd.
org.apache.hadoop.hive.metastore.api. PartitionsByExprRequest	Description of partitions by expression request.
org.apache.hadoop.hive.metastore.api. PartitionsByExprResult	Description of partitions by expression result.
org.apache.hadoop.hive.metastore.api. PartitionsStatsRequest	Description of partition statistics request.

Class	Description
org.apache.hadoop.hive.metastore.api. PartitionsStatsResult	Description of partitions statistics result.
org.apache.hadoop.hive.metastore.api. PrincipalPrivilegeSet	Description of setting principal privilege.
org.apache.hadoop.hive.metastore.api. PrivilegeBag	Description of privilege bag.
org.apache.hadoop.hive.metastore.api. PrivilegeGrantInfo	Description of granted privilege info.
org.apache.hadoop.hive.metastore.api. ResourceUri	Description of resource URI.
org.apache.hadoop.hive.metastore.api. Role	Description of role.
org.apache.hadoop.hive.metastore.api. RolePrincipalGrant	Description of granted principal role.
org.apache.hadoop.hive.metastore.api. Schema	Description of schema.
org.apache.hadoop.hive.metastore.api. SerDeInfo	Description of serializer deserializer information.
org.apache.hadoop.hive.metastore.api. SetPartitionsStatsRequest	Description of setting partition statistics on request.
org.apache.hadoop.hive.metastore.api. ShowCompactRequest	Show compaction on request.
org.apache.hadoop.hive.metastore.api. ShowCompactResponse	Show compaction on response.
org.apache.hadoop.hive.metastore.api. ShowCompactResponseElement	Show compaction response element.
org.apache.hadoop.hive.metastore.api. ShowLocksRequest	Show locks on request.
org.apache.hadoop.hive.metastore.api. ShowLocksResponse	Show locks on response.
org.apache.hadoop.hive.metastore.api. ShowLocksResponseElement	Show locks response element.
org.apache.hadoop.hive.metastore.api. SkewedInfo	Description for skewed information.
org.apache.hadoop.hive.metastore.api. StorageDescriptor	Description for storage descriptor.
org.apache.hadoop.hive.metastore.api. StringColumnStatisticsData	Description for string column statistics data.
org.apache.hadoop.hive.metastore.api. Table	Description for data.
org.apache.hadoop.hive.metastore.api. TableStatsRequest	Description for table statistics request.
org.apache.hadoop.hive.metastore.api. TableStatsResult	Description for table statistics result.
org.apache.hadoop.hive.metastore.api. AlreadyExistsException	Custom exception to handle already exists error.
org.apache.hadoop.hive.metastore.api. ConfigValSecurityException	Custom exception to handle configuration value security error.
org.apache.hadoop.hive.metastore.api. IndexAlreadyExistsException	Custom exception to handle index already exists error.
org.apache.hadoop.hive.metastore.api. InvalidInputException	Custom exception for invalid input error.
org.apache.hadoop.hive.metastore.api. InvalidObjectException	Custom exception for invalid object error.

Class	Description
org.apache.hadoop.hive.metastore.api.InvalidOperationException	Custom exception for invalid operation error.
org.apache.hadoop.hive.metastore.api.InvalidPartitionException	Custom exception for invalid partition error.
org.apache.hadoop.hive.metastore.api.MetaException	Custom exception for metastore related error.
org.apache.hadoop.hive.metastore.api.NoSuchLockException	Custom exception in case of invalid lock.
org.apache.hadoop.hive.metastore.api.NoSuchObjectException	Custom exception in case of invalid object.
org.apache.hadoop.hive.metastore.api.NoSuchTxnException	Custom exception in case of invalid transaction.
org.apache.hadoop.hive.metastore.api.TxnAbortedException	Custom exception in case of aborted transaction.
org.apache.hadoop.hive.metastore.api.TxnOpenException	Custom exception in case of not close transaction.
org.apache.hadoop.hive.metastore.api.UnknownDBException	Custom exception in case of unknown database.
org.apache.hadoop.hive.metastore.api.UnknownPartitionException	Custom exception in case of unknown partition.
org.apache.hadoop.hive.metastore.api.UnknownTableException	Custom partition in case of unknown table.
org.apache.hadoop.hive.metastore.events.EventCleanerTask	Cleaning tasks from event table.
org.apache.hadoop.hive.metastore.parser.ExpressionTree	Represents the filter as a binary tree.
org.apache.hadoop.hive.metastore.txn.CompactionInfo	Information on a possible or running compaction.
org.apache.hadoop.hive.metastore.txn.CompactionInfo	Utility methods for creating and destroying txn database/schema, plus methods for querying against metastore tables.
org.apache.hadoop.hive ql.Context	Context for Semantic Analyzers.
org.apache.hadoop.hive ql.Driver	Driver to process commands on cluster.
org.apache.hadoop.hive ql.QueryPlan	QueryPlan can be serialized to disk to restart/resume the progress of it in the future, either within or outside of the current JVM.
org.apache.hadoop.hive ql.QueryProperties	QueryProperties.
org.apache.hadoop.hive ql.exec.AbstractFileMergeOperator	Fast file merge operator for ORC and RCfile.
org.apache.hadoop.hive ql.exec.AbstractMapJoinOperator	Class to handle join input's join keys.
org.apache.hadoop.hive ql.exec.AppMasterEventOperator	AppMasterEventOperator sends any rows it receives to the Tez AM.
org.apache.hadoop.hive ql.exec.AutoProgressor	AutoProgressor periodically sends updates to the job tracker so that it doesn't consider this task attempt dead if there is a long period of inactivity.
org.apache.hadoop.hive ql.exec.CollectOperator	Buffers rows emitted by other operators.
org.apache.hadoop.hive ql.exec.ColumnStatsTask	ColumnStatsTask implementation.

Class	Description
org.apache.hadoop.hive.ql.exec. ColumnStatsUpdateTask	ColumnStatsUpdateTask implementation.
org.apache.hadoop.hive.ql.exec. CommonJoinOperator	Join operator implementation.
org.apache.hadoop.hive.ql.exec. CommonMergeJoinOperator	Consolidate the join algorithms to either hash based joins (MapJoinOperator) or sort-merge based joins, this operator is being introduced.
org.apache.hadoop.hive.ql.exec. ConditionalTask	Conditional Task implementation.
org.apache.hadoop.hive.ql.exec. DDLTask	DDLTask implementation.
org.apache.hadoop.hive.ql.exec. DefaultBucketMatcher	Finding right bucket.
org.apache.hadoop.hive.ql.exec. DemuxOperator	DemuxOperator is an operator used by MapReduce Jobs optimized by CorrelationOptimizer.
org.apache.hadoop.hive.ql.exec. DummyStoreOperator	For SortMerge joins, this is a dummy operator, which stores the row for the small table before it reaches the sort merge join operator.
org.apache.hadoop.hive.ql.exec. ExplainTask	ExplainTask implementation.
org.apache.hadoop.hive.ql.exec. FetchOperator	FetchTask implementation.
org.apache.hadoop.hive.ql.exec. FetchTask	FetchTask implementation.
org.apache.hadoop.hive.ql.exec. FileSinkOperator	File Sink operator implementation.
org.apache.hadoop.hive.ql.exec. FilterOperator	Filter operator implementation.
org.apache.hadoop.hive.ql.exec. ForwardOperator	Forward Operator Just forwards.
org.apache.hadoop.hive.ql.exec. FunctionRegistry	FunctionRegistry.
org.apache.hadoop.hive.ql.exec. FunctionTask	FunctionTask.
org.apache.hadoop.hive.ql.exec. GroupByOperator	GroupBy operator implementation.
org.apache.hadoop.hive.ql.exec. HashTableDummyOperator	Hash table operator implementation.
org.apache.hadoop.hive.ql.exec. HashTableSinkOperator	Hash table sink operator implementation.
org.apache.hadoop.hive.ql.exec. JoinOperator	Join operator implementation.
org.apache.hadoop.hive.ql.exec. LateralViewForwardOperator	LateralViewForwardOperator.
org.apache.hadoop.hive.ql.exec. LateralViewJoinOperator	The lateral view join operator is used for FROM src LATERAL VIEW udtf()...
org.apache.hadoop.hive.ql.exec. LimitOperator	Limit operator implementation Limits the number of rows to be passed on.
org.apache.hadoop.hive.ql.exec. ListSinkOperator	For fetch task with operator tree, row read from FetchOperator is processed via operator tree and finally arrives to this operator.
org.apache.hadoop.hive.ql.exec. MapJoinOperator	Map side Join operator implementation.
org.apache.hadoop.hive.ql.exec. MapOperator	Map operator.
org.apache.hadoop.hive.ql.exec. MapredContext	Runtime context of MapredTask providing additional information to GenericUDF
org.apache.hadoop.hive.ql.exec. MoveTask	MoveTask implementation.
org.apache.hadoop.hive.ql.exec. MuxOperator	MuxOperator is used in the Reduce side of MapReduce jobs optimized by Correlation Optimizer.

Class	Description
org.apache.hadoop.hive ql.exec. ObjectCacheFactory	ObjectCacheFactory returns the appropriate cache depending on settings in the hive conf.
org.apache.hadoop.hive ql.exec. Operator	Base operator implementation.
org.apache.hadoop.hive ql.exec. OperatorFactory	OperatorFactory.
org.apache.hadoop.hive ql.exec. OperatorUtils	Utilities to handle operators.
org.apache.hadoop.hive ql.exec. OrcFileMergeOperator	Fast file merge operator for ORC files.
org.apache.hadoop.hive ql.exec. PTFOperator	Class to handle partitioned table functions operators.
org.apache.hadoop.hive ql.exec. PTFPartition	Represents a collection of rows that is acted upon by a TableFunction or a WindowFunction.
org.apache.hadoop.hive ql.exec. PTFRollingPartition	Represents a collection of rows that is acted upon by a TableFunction or a WindowFunction.
org.apache.hadoop.hive ql.exec. PTFUtils	Utilities to handle partitioned table functions.
org.apache.hadoop.hive ql.exec. PartitionKeySampler	Class to handle partition key sampler.
org.apache.hadoop.hive ql.exec. RCFileMergeOperator	Fast file merge operator for RC files.
org.apache.hadoop.hive ql.exec. ReduceSinkOperator	Reduce Sink Operator sends output to the reduce stage.
org.apache.hadoop.hive ql.exec. Registry	Function registry.
org.apache.hadoop.hive ql.exec. SMBMapJoinOperator	Sorted Merge Map Join Operator.
org.apache.hadoop.hive ql.exec. ScriptOperator	ScriptOperator.
org.apache.hadoop.hive ql.exec. SelectOperator	Select operator implementation.
org.apache.hadoop.hive ql.exec. SkewJoinHandler	At runtime in Join, output big keys in one table into one corresponding directories, and all same keys in other tables into different dirs (one for each table).
org.apache.hadoop.hive ql.exec. SparkHashTableSinkOperator	Operator for spark hashtable sink.
org.apache.hadoop.hive ql.exec. StatsNoJobTask	StatsNoJobTask is used in cases where stats collection is the only task for the given query (no parent MR or Tez job).
org.apache.hadoop.hive ql.exec. TableScanOperator	Table Scan Operator If the data is coming from the map-reduce framework, just forward it.
org.apache.hadoop.hive ql.exec. Task	Task implementation.
org.apache.hadoop.hive ql.exec. TaskResult	TaskResult implementation.
org.apache.hadoop.hive ql.exec. TemporaryHashSinkOperator	Operator temporary hash sink.
org.apache.hadoop.hive ql.exec. TerminalOperator	Terminal Operator Base Class.
org.apache.hadoop.hive ql.exec. TezDummyStoreOperator	A dummy store operator same as the dummy store operator but for tez.
org.apache.hadoop.hive ql.exec. TopNHash	Stores binary key/value in sorted manner to get top-n key/value TODO: rename to TopNHeap?
org.apache.hadoop.hive ql.exec. UDTFOperator	UDTFOperator.
org.apache.hadoop.hive ql.exec. UnionOperator	Union Operator Just forwards.
org.apache.hadoop.hive ql.exec. Utilities	Utilities.

Class	Description
org.apache.hadoop.hive ql.exec.mr. ExecDriver	ExecDriver is the central class in co-ordinating execution of any map-reduce task.
org.apache.hadoop.hive ql.exec.mr. ExecMapper	ExecMapper is the generic Map class for Hive.
org.apache.hadoop.hive ql.exec.mr. ExecMapperContext	ExecMapperContext is the generic Map context class for Hive.
org.apache.hadoop.hive ql.exec.mr. HadoopJobExecHelper	Handle information about hadoop job.
org.apache.hadoop.hive ql.exec.mr. JobDebugger	JobDebugger takes a RunningJob that has failed and grabs the top 4 failing tasks and outputs this information to the Hive CLI.
org.apache.hadoop.hive ql.exec.mr. MapredLocalTask	MapredLocalTask represents any local work (i.e.: client side work) that hive needs to execute.
org.apache.hadoop.hive ql.exec.mr. Throttle	Intelligence to make clients wait if the cluster is in a bad state.
org.apache.hadoop.hive ql.exec.persistence. BytesBytesMultiHashMap	HashMap that maps byte arrays to byte arrays with limited functionality necessary for MapJoin hash tables, with small memory overhead.
org.apache.hadoop.hive ql.exec.persistence. HashMapWrapper	Simple wrapper for persistent Hashmap implementing only the put/get/remove/clear interface.
org.apache.hadoop.hive ql.exec.persistence. HybridHashTableContainer	Hash table container that can have many partitions -- each partition has its own hashmap, as well as row container for small table and big table.
org.apache.hadoop.hive ql.exec.persistence. KeyValueContainer	An eager key/value container that puts every row directly to output stream.
org.apache.hadoop.hive ql.exec.persistence. MapJoinBytesTableContainer	Table container that serializes keys and values using LazyBinarySerDe into BytesBytesMultiHashMap, with very low memory overhead.
org.apache.hadoop.hive ql.exec.persistence. MapJoinKey	The base class for MapJoinKey.
org.apache.hadoop.hive ql.exec.persistence. MapJoinTableContainerSerDe	Serialization/deserialization of table container for join.
org.apache.hadoop.hive ql.exec.persistence. ObjectContainer	An eager object container that puts every row directly to output stream.
org.apache.hadoop.hive ql.exec.persistence. RowContainer	Simple persistent container for rows.
org.apache.hadoop.hive ql.exec.persistence. UnwrapRowContainer	Unwraps values from current key with valueIndex in mapjoin desc.
org.apache.hadoop.hive ql.exec.spark. GroupByShuffler	Shuffle group by operator.
org.apache.hadoop.hive ql.exec.spark. HiveSparkClientFactory	Factory class for spark client.
org.apache.hadoop.hive ql.exec.spark. LocalHiveSparkClient	LocalSparkClient submit Spark job in local driver, it's responsible for build spark client environment and execute spark work.
org.apache.hadoop.hive ql.exec.spark. MapInput	Input for mapper.
org.apache.hadoop.hive ql.exec.spark. MapTran	Mapper tran.
org.apache.hadoop.hive ql.exec.spark. ReduceTran	Reduce tran.

Class	Description
org.apache.hadoop.hive.ql.exec.spark. RemoteHiveSparkClient	RemoteSparkClient is a wrapper of org.apache.hive.spark.client.SparkClient, which wrap a spark job request and send to an remote SparkContext.
org.apache.hadoop.hive.ql.exec.spark. ShuffleTran	Shuffle tran.
org.apache.hadoop.hive.ql.exec.spark. SortByShuffler	Sorting class for shuffler.
org.apache.hadoop.hive.ql.exec.spark. SparkTask	Description of spark task.
org.apache.hadoop.hive.ql.exec.spark. SparkUtilities	Contains utilities methods used as part of Spark tasks.
org.apache.hadoop.hive.ql.exec.spark.session. SparkSessionImpl	Implementation of spark session.
org.apache.hadoop.hive.ql.exec.spark.status.impl. JobMetricsListener	Listener for job metrics.
org.apache.hadoop.hive.ql.exec.spark.status.impl. LocalSparkJobStatus	Spark job local status.
org.apache.hadoop.hive.ql.exec.spark.status.impl. RemoteSparkJobStatus	Used with remove spark client.
org.apache.hadoop.hive.ql.exec.tez. DagUtils	DagUtils.
org.apache.hadoop.hive.ql.exec.tez. DynamicPartitionPruner	DynamicPartitionPruner takes a list of assigned partitions at runtime (split generation) and prunes them using events generated during execution of the dag.
org.apache.hadoop.hive.ql.exec.tez. HiveSplitGenerator	Generates splits inside the AM on the cluster.
org.apache.hadoop.hive.ql.exec.tez. MapRecordProcessor	Process input from tez LogicalInput and write output - for a map plan Just pump the records through the query plan.
org.apache.hadoop.hive.ql.exec.tez. MapRecordSource	Process input from tez LogicalInput and write output - for a map plan Just pump the records through the query plan.
org.apache.hadoop.hive.ql.exec.tez. MergeFileRecordProcessor	Record processor for fast merging of files.
org.apache.hadoop.hive.ql.exec.tez. RecordProcessor	Process input from tez LogicalInput and write output It has different subclasses for map and reduce processing
org.apache.hadoop.hive.ql.exec.tez. ReduceRecordProcessor	Process input from tez LogicalInput and write output - for a map plan Just pump the records through the query plan.
org.apache.hadoop.hive.ql.exec.tez. ReduceRecordSource	Process input from tez LogicalInput and write output - for a map plan Just pump the records through the query plan.
org.apache.hadoop.hive.ql.exec.tez. SplitGrouper	SplitGrouper is used to combine splits based on head room and locality.
org.apache.hadoop.hive.ql.exec.tez. TezJobMonitor	TezJobMonitor keeps track of a tez job while it's being executed.
org.apache.hadoop.hive.ql.exec.tez. TezProcessor	Hive processor for Tez that forms the vertices in Tez and processes the data.
org.apache.hadoop.hive.ql.exec.tez. TezSessionPoolManager	This class is for managing multiple tez sessions particularly when HiveServer2 is being used to submit queries.
org.apache.hadoop.hive.ql.exec.tez. TezSessionState	Holds session state related to Tez

Class	Description
org.apache.hadoop.hive ql.exec.tez. TezTask	TezTask handles the execution of TezWork.
org.apache.hadoop.hive ql.exec.tez.tools. KeyValueInputMerger	A KeyValuesReader implementation that returns a sorted stream of key-values by doing a sorted merge of the key-value in LogicalInputs.
org.apache.hadoop.hive ql.exec.tez.tools. KeyValuesInputMerger	A KeyValuesReader implementation that returns a sorted stream of key-values by doing a sorted merge of the key-value in LogicalInputs.
org.apache.hadoop.hive ql.exec.vector. BytesColumnVector	This class supports string and binary data by value reference.
org.apache.hadoop.hive ql.exec.vector. ColumnVector	ColumnVector contains the shared structure for the sub-types, including NULL information, and whether this vector repeats, i.e.
org.apache.hadoop.hive ql.exec.vector. DecimalColumnVector	A vector of HiveDecimalWritable objects.
org.apache.hadoop.hive ql.exec.vector. DoubleColumnVector	This class represents a nullable double precision floating point column vector.
org.apache.hadoop.hive ql.exec.vector. LongColumnVector	This class represents a nullable int column vector.
org.apache.hadoop.hive ql.exec.vector. TimestampUtils	Utilities for Timestamps and the relevant conversions.
org.apache.hadoop.hive ql.exec.vector. VectorAppMasterEventOperator	App Master Event operator implementation.
org.apache.hadoop.hive ql.exec.vector. VectorAssignRow	This class assigns specified columns of a row from a Writable row objects.
org.apache.hadoop.hive ql.exec.vector. VectorColumnOrderedMap	This class collects column information for mapping vector columns, including the hive type name.
org.apache.hadoop.hive ql.exec.vector. VectorColumnInfo	Class to keep information on a set of typed vector columns.
org.apache.hadoop.hive ql.exec.vector. VectorCopyRow	This class copies specified columns of a row from one VectorizedRowBatch to another.
org.apache.hadoop.hive ql.exec.vector. VectorDeserializeRow	This class deserializes a serialization format into a row of a VectorizedRowBatch.
org.apache.hadoop.hive ql.exec.vector. VectorExtractRow	This class extracts specified VectorizedRowBatch row columns into writables.
org.apache.hadoop.hive ql.exec.vector. VectorFileSinkOperator	File Sink operator implementation.
org.apache.hadoop.hive ql.exec.vector. VectorFilterOperator	Filter operator implementation.
org.apache.hadoop.hive ql.exec.vector. VectorGroupByOperator	Vectorized GROUP BY operator implementation.
org.apache.hadoop.hive ql.exec.vector. VectorHashKeyWrapper	A hash map key wrapper for vectorized processing.
org.apache.hadoop.hive ql.exec.vector. VectorLimitOperator	Limit operator implementation Limits the number of rows to be passed on.
org.apache.hadoop.hive ql.exec.vector. VectorMapJoinBaseOperator	The *NON-NATIVE* base vector map join operator class used by VectorMapJoinOperator and VectorMapJoinOuterFilteredOperator.

Class	Description
org.apache.hadoop.hive ql.exec.vector. VectorMapJoinOperator	The vectorized version of the MapJoinOperator.
org.apache.hadoop.hive ql.exec.vector. VectorMapJoinOuterFilteredOperator	This is the *NON-NATIVE* vector map join operator for just LEFT OUTER JOIN and filtered.
org.apache.hadoop.hive ql.exec.vector. VectorMapOperator	The vectorized MapOperator.
org.apache.hadoop.hive ql.exec.vector. VectorReduceSinkOperator	The vectorized reduce sink operator.
org.apache.hadoop.hive ql.exec.vector. VectorSMBMapJoinOperator	VectorSMBJoinOperator.
org.apache.hadoop.hive ql.exec.vector. VectorSelectOperator	Select operator implementation.
org.apache.hadoop.hive ql.exec.vector. VectorSerializeRow	This class serializes columns from a row in a VectorizedRowBatch into a serialization format.
org.apache.hadoop.hive ql.exec.vector. VectorizationContext	Context class for vectorization execution.
org.apache.hadoop.hive ql.exec.vector. VectorizedBatchUtil	The vectorized MapOperator.
org.apache.hadoop.hive ql.exec.vector. VectorizedRowBatch	A VectorizedRowBatch is a set of rows, organized with each column as a vector.
org.apache.hadoop.hive ql.exec.vector. VectorizedRowBatchCtx	Context for Vectorized row batch.
org.apache.hadoop.hive ql.exec.vector.expressions. CastDecimalToTimestamp	Type cast decimal to timestamp.
org.apache.hadoop.hive ql.exec.vector.expressions. CastTimestampToDecimal	To be used to cast timestamp to decimal.
org.apache.hadoop.hive ql.exec.vector.expressions. ColAndCol	Evaluate AND of 2 or more boolean columns and store the boolean result in the output boolean column.
org.apache.hadoop.hive ql.exec.vector.expressions. ColOrCol	Evaluate OR of 2 or more boolean columns and store the boolean result in the output boolean column.
org.apache.hadoop.hive ql.exec.vector.expressions. ConstantVectorExpression	Constant is represented as a vector with repeating values.
org.apache.hadoop.hive ql.exec.vector.expressions. DecimalUtil	Utility functions for vector operations on decimal values.
org.apache.hadoop.hive ql.exec.vector.expressions. FilterExprOrExpr	Represents an Or expression.
org.apache.hadoop.hive ql.exec.vector.expressions. FilterStringColumnInList	Evaluate an IN filter on a batch for a vector of strings.
org.apache.hadoop.hive ql.exec.vector.expressions. FuncRoundWithNumDigitsDecimalToDecimal	Function for rounding decimals.
org.apache.hadoop.hive ql.exec.vector.expressions. MathExpr	Math expression evaluation helper functions.
org.apache.hadoop.hive ql.exec.vector.expressions. NullUtil	Utility functions to handle null propagation.
org.apache.hadoop.hive ql.exec.vector.expressions. StringColumnInList	Evaluate an IN boolean expression (not a filter) on a batch for a vector of strings.

Class	Description
org.apache.hadoop.hive ql.exec.vector.expressions. String Expr	String expression evaluation helper functions.
org.apache.hadoop.hive ql.exec.vector.expressions. VectorUDFDateAddColCol	Vectorized user defined function for adding columns.
org.apache.hadoop.hive ql.exec.vector.expressions. VectorUDFDateAddColScalar	Vectorized user defined function for adding column and scalar.
org.apache.hadoop.hive ql.exec.vector.expressions. VectorUDFDateDiffColCol	Vectorized user defined function for finding difference between two columns.
org.apache.hadoop.hive ql.exec.vector.expressions. VectorUDFDateLong	Vectorized version of TO_DATE(TIMESTAMP)/TO_DATE(DATE).
org.apache.hadoop.hive ql.exec.vector.expressions. VectorUDFDateString	Vectorized version of TO_DATE(STRING) As TO_DATE() now returns DATE type, this should be the same behavior as the DATE cast operator.
org.apache.hadoop.hive ql.exec.vector.mapjoin. VectorMapJoinCommonOperator	Common operator class for native vectorized map join.
org.apache.hadoop.hive ql.exec.vector.mapjoin. VectorMapJoinGenerateResultOperator	Contains methods for generating vectorized join results and forwarding batches.
org.apache.hadoop.hive ql.exec.vector.mapjoin. VectorMapJoinInnerBigOnlyGenerateResultOperator	This class has methods for generating vectorized join results for the big table only variation of inner joins.
org.apache.hadoop.hive ql.exec.vector.mapjoin. VectorMapJoinInnerBigOnlyLongOperator	Specialized class for doing a vectorized map join that is an inner join on a Single-Column Long and only big table columns appear in the join result so a hash multi-set is used.
org.apache.hadoop.hive ql.exec.vector.mapjoin. VectorMapJoinInnerBigOnlyMultiKeyOperator	Specialized class for doing a vectorized map join that is an inner join on Multi-Key and only big table columns appear in the join result so a hash multi-set is used.
org.apache.hadoop.hive ql.exec.vector.mapjoin. VectorMapJoinInnerBigOnlyStringOperator	Specialized class for doing a vectorized map join that is an inner join on a Single-Column String and only big table columns appear in the join result so a hash multi-set is used.
org.apache.hadoop.hive ql.exec.vector.mapjoin. VectorMapJoinInnerGenerateResultOperator	Contains methods for generating vectorized join results for inner joins.
org.apache.hadoop.hive ql.exec.vector.mapjoin. VectorMapJoinInnerLongOperator	Specialized class for doing a vectorized map join that is an inner join on a Single-Column Long and only big table columns appear in the join result so a hash multi-set is used.
org.apache.hadoop.hive ql.exec.vector.mapjoin. VectorMapJoinInnerMultiKeyOperator	Specialized class for doing a vectorized map join that is an inner join on a Multi-Key using a hash map.
org.apache.hadoop.hive ql.exec.vector.mapjoin. VectorMapJoinInnerStringOperator	Specialized class for doing a vectorized map join that is an inner join on a Single-Column String using a hash map.
org.apache.hadoop.hive ql.exec.vector.mapjoin. VectorMapJoinLeftSemiGenerateResultOperator	Contains methods for generating vectorized join results for left semi joins.
org.apache.hadoop.hive ql.exec.vector.mapjoin. VectorMapJoinLeftSemiLongOperator	Specialized class for doing a vectorized map join that is an left semi join on a Single-Column Long using a hash set.
org.apache.hadoop.hive ql.exec.vector.mapjoin. VectorMapJoinLeftSemiMultiKeyOperator	Specialized class for doing a vectorized map join that is an left semi join on Multi-Key using hash set.

Class	Description
org.apache.hadoop.hive.ql.exec.vector.mapjoin. VectorMapJoinLeftSemiStringOperator	Specialized class for doing a vectorized map join that is an left semi join on a Single-Column String using a hash set.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. VectorMapJoinOuterGenerateResultOperator	Contains methods for generating vectorized join results for outer joins.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. VectorMapJoinOuterLongOperator	Specialized class for doing a vectorized map join that is an outer join on a Single-Column Long using a hash map.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. VectorMapJoinOuterMultiKeyOperator	Specialized class for doing a vectorized map join that is an outer join on Multi-Key using a hash map.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. VectorMapJoinOuterStringOperator	Specialized class for doing a vectorized map join that is an outer join on a Single-Column String using a hash map.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. VectorMapJoinRowBytesContainer	An eager bytes container that puts row bytes to an output stream.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast. VectorMapJoinFastBytesHashMap	Bytes key hash map optimized for vector map join. This is the abstract base for the multi-key and string bytes key hash map implementations.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast. VectorMapJoinFastBytesHashMultiSet	Bytes key hash multi-set optimized for vector map join. This is the abstract base for the multi-key and string bytes key hash multi-set implementations.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast. VectorMapJoinFastBytesHashUtil	Utilities for bytes key hash multi-set optimized for vector map join.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast. VectorMapJoinFastHashTable	Vector map join fast hash table.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast. VectorMapJoinFastKeyStore	Vector map join fast key store.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast. VectorMapJoinFastLongHashMap	Vector map join fast long hash map.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast. VectorMapJoinFastLongHashMultiSet	Vector map join fast long hash multi set.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast. VectorMapJoinFastLongHashSet	A single LONG key hash set optimized for vector map join.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast. VectorMapJoinFastLongHashTable	A single long value map optimized for vector map join.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast. VectorMapJoinFastLongHashUtil	Utilities for vector map join of single long value.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast. VectorMapJoinFastMultiKeyHashMap	A multi-key value hash map optimized for vector map join. The key is stored as the provided bytes (uninterpreted).
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast. VectorMapJoinFastMultiKeyHashMultiSet	A multi-key hash multi-set optimized for vector map join. The key is stored as the provided bytes (uninterpreted).
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast. VectorMapJoinFastMultiKeyHashSet	A multi-key hash set optimized for vector map join. The key is stored as the provided bytes (uninterpreted).
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast. VectorMapJoinFastStringCommon	A single byte array value hash map optimized for vector map join.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast. VectorMapJoinFastTableContainer	HashTableLoader for Tez constructs the hashtable from records read from a broadcast edge.

Class	Description
org.apache.hadoop.hive.ql.exec.vector.mapjoin.hashtable. VectorMapJoinHashMapResult	Abstract class for a hash map result. For reading the values, one-by-one.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.hashtable. VectorMapJoinHashTableResult	Root abstract class for a hash table result.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.optimized. VectorMapJoinOptimizedCreateHashTable	Create hash table for vector map join.
org.apache.hadoop.hive.ql.hooks. HookContext	Hook Context keeps all the necessary information for all the hooks.
org.apache.hadoop.hive.ql.hooks. PostExecutePrinter	Implementation of a post execute hook that simply prints out its parameters to standard output.
org.apache.hadoop.hive.ql.hooks. PreExecutePrinter	Implementation of a pre execute hook that simply prints out its parameters to standard output.
org.apache.hadoop.hive.ql.index. HiveIndex	Holds index related constants.
org.apache.hadoop.hive.ql.index. HiveIndexQueryContext	Used to pass information between the IndexProcessor and the plugin IndexHandler during query processing
org.apache.hadoop.hive.ql.index. HiveIndexResult	HiveIndexResult parses the input stream from an index query to generate a list of file splits to query.
org.apache.hadoop.hive.ql.index. HiveIndexedInputFormat	Input format for doing queries that use indexes.
org.apache.hadoop.hive.ql.index. IndexPredicateAnalyzer	IndexPredicateAnalyzer decomposes predicates, separating the parts which can be satisfied by an index from the parts which cannot.
org.apache.hadoop.hive.ql.index. IndexSearchCondition	IndexSearchCondition represents an individual search condition found by IndexPredicateAnalyzer.
org.apache.hadoop.hive.ql.index. TableBasedIndexHandler	Index handler for indexes that use tables to store indexes.
org.apache.hadoop.hive.ql.index.compact. HiveCompactIndexInputFormat	Hive compact index input format.
org.apache.hadoop.hive.ql.io. AcidUtils	Utilities that are shared by all of the ACID input and output formats.
org.apache.hadoop.hive.ql.io. BucketizedHiveInputFormat	BucketizedHiveInputFormat serves the similar function as hiveInputFormat but its getSplits() always group splits from one input file into one wrapper split.
org.apache.hadoop.hive.ql.io. CombineHiveInputFormat	CombineHiveInputFormat is a parameterized InputFormat which looks at the path name and determine the correct InputFormat for that path name from mapredPlan.pathToPartitionInfo().
org.apache.hadoop.hive.ql.io. HiveFileFormatUtils	An util class for various Hive file format tasks.
org.apache.hadoop.hive.ql.io. HiveInputFormat	HiveInputFormat is a parameterized InputFormat which looks at the path name and determine the correct InputFormat for that path name from mapredPlan.pathToPartitionInfo().
org.apache.hadoop.hive.ql.io. IOConstants	Input output constants.
org.apache.hadoop.hive.ql.io. IOContext	IOContext basically contains the position information of the current key/value.
org.apache.hadoop.hive.ql.io. NullRowsInputFormat	NullRowsInputFormat outputs null rows, maximum 100.
org.apache.hadoop.hive.ql.io. OneNullRowInputFormat	OneNullRowInputFormat outputs one null row.

Class	Description
org.apache.hadoop.hive ql.io. RCFileInputFormat	RCFileInputFormat.
org.apache.hadoop.hive ql.io. SequenceFileInputFormatChecker	SequenceFileInputFormatChecker.
org.apache.hadoop.hive ql.io.avro. AvroContainerOutputFormat	Write to an Avro file from a Hive process.
org.apache.hadoop.hive ql.io.merge. MergeFileMapper	Mapper for fast file merging of ORC and RC files.
org.apache.hadoop.hive ql.io.merge. MergeFileTask	Task for fast merging of ORC and RC files.
org.apache.hadoop.hive ql.io.orc. CompressionKind	An enumeration that lists the generic compression algorithms that can be applied to ORC files.
org.apache.hadoop.hive ql.io.orc. OrcFile	Contains factory methods to read or write ORC files.
org.apache.hadoop.hive ql.io.orc. OrcFileKeyWrapper	Key for OrcFileMergeMapper task.
org.apache.hadoop.hive ql.io.orc. OrcFileStripeMergeRecordReader	Record reader for orc file stripe merge.
org.apache.hadoop.hive ql.io.orc. OrcFileValueWrapper	Value for OrcFileMergeMapper.
org.apache.hadoop.hive ql.io.orc. OrcInputFormat	A MapReduce/Hive input format for ORC files.
org.apache.hadoop.hive ql.io.orc. OrcNewSplit	OrcFileSplit.
org.apache.hadoop.hive ql.io.orc. OrcRecordUpdater	A RecordUpdater where the files are stored as ORC.
org.apache.hadoop.hive ql.io.orc. OrcSerde	A serde class for ORC.
org.apache.hadoop.hive ql.io.orc. OrcSplit	OrcFileSplit.
org.apache.hadoop.hive ql.io.orc. ReaderImpl	Implementation of record reader.
org.apache.hadoop.hive ql.io.orc. VectorizedOrcInputFormat	A MapReduce/Hive input format for ORC files.
org.apache.hadoop.hive ql.io.orc. WriterImpl	An ORC file writer.
org.apache.hadoop.hive ql.io.parquet. LeafFilterFactory	Factory class for leaf filter.
org.apache.hadoop.hive ql.io.parquet. MapredParquetOutputFormat	A Parquet OutputFormat for Hive (with the deprecated package mapred)
org.apache.hadoop.hive ql.io.parquet.convert. DataWritableRecordConverter	A MapWritableReadSupport, encapsulates the tuples
org.apache.hadoop.hive ql.io.parquet.convert. ETypeConverter.BinaryConverter	ETypeConverter is an easy way to set the converter for the right type.
org.apache.hadoop.hive ql.io.parquet.convert. HiveCollectionConverter	Converter for collections.
org.apache.hadoop.hive ql.io.parquet.convert. HiveGroupConverter	Converter for groups.
org.apache.hadoop.hive ql.io.parquet.convert. HiveStructConverter	A MapWritableGroupConverter, real converter between hive and parquet types recursively for complex types.
org.apache.hadoop.hive ql.io.parquet.read. DataWritableReadSupport	A MapWritableReadSupport Manages the translation between Hive and Parquet
org.apache.hadoop.hive ql.io.parquet.read. ParquetRecordReaderWrapper	Wrapper for parquet record reader.
org.apache.hadoop.hive ql.io.parquet.serde. ParquetHiveSerDe	A ParquetHiveSerDe for Hive (with the deprecated package mapred)

Class	Description
org.apache.hadoop.hive ql.io.parquet.write. DataWritableWriter	DataWritableWriter sends a record to the Parquet API with the expected schema in order to be written to a file.
org.apache.hadoop.hive ql.io.parquet.write. ParquetRecordWriterWrapper	Wrapper for parquet record writer.
org.apache.hadoop.hive ql.io.rcfile.stats. PartialScanMapper	PartialScanMapper.
org.apache.hadoop.hive ql.io.rcfile.stats. PartialScanTask	PartialScanTask.
org.apache.hadoop.hive ql.io.rcfile.stats. PartialScanWork	Partial Scan Work.
org.apache.hadoop.hive ql.io.rcfile.truncate. ColumnTruncateMapper	A factory for creating SearchArguments, as well as modifying those created by this factory.
org.apache.hadoop.hive ql.io.rcfile.truncate. ColumnTruncateTask	Base class for operator graph walker this class takes list of starting ops and walks them one by one.
org.apache.hadoop.hive ql.io.sarg. SearchArgumentFactory	A factory for creating SearchArguments, as well as modifying those created by this factory.
org.apache.hadoop.hive ql.lib. DefaultGraphWalker	Base class for operator graph walker this class takes list of starting ops and walks them one by one.
org.apache.hadoop.hive ql.lib. RuleExactMatch	Implementation of the Rule interface for Nodes Used in Node dispatching to dispatch process/visitor functions for Nodes.
org.apache.hadoop.hive ql.lockmgr. DbLockManager	An implementation of HiveLockManager for use with org.apache.hadoop.hive ql.lockmgr. DbTxnManager .
org.apache.hadoop.hive ql.lockmgr. DbTxnManager	An implementation of HiveTxnManager that stores the transactions in the metastore database.
org.apache.hadoop.hive ql.lockmgr. HiveLockObject	The class is used to uniquely identify a HiveLockObject.
org.apache.hadoop.hive ql.lockmgr. LockException	Exception from lock manager.
org.apache.hadoop.hive ql.lockmgr.zookeeper. ZooKeeperHiveLock	The class is used to uniquely identify ZookeeperHiveLock.
org.apache.hadoop.hive ql.lockmgr.zookeeper. ZooKeeperHiveLockManager	Zookeeper lock manager.
org.apache.hadoop.hive ql.log. PerfLogger	PerfLogger.
org.apache.hadoop.hive ql.metadata. Hive	Contains functions that implement meta data/DDDL operations using calls to the metastore.
org.apache.hadoop.hive ql.metadata. HiveException	Generic exception class for Hive.
org.apache.hadoop.hive ql.metadata. HiveMetaStoreChecker	Verify that the information in the metastore matches what is on the filesystem.
org.apache.hadoop.hive ql.metadata. HiveUtils	General collection of helper functions.
org.apache.hadoop.hive ql.metadata. Partition	A Hive Table Partition: is a fundamental storage unit within a Table.
org.apache.hadoop.hive ql.metadata. SessionHiveMetaStoreClient	Client for hivemetastore during session.
org.apache.hadoop.hive ql.metadata. Table	A Hive Table: is a fundamental unit of data in Hive that shares a common schema/DDDL.
org.apache.hadoop.hive ql.metadata. VirtualColumn	Provides metadata that is not stored in table itself.
org.apache.hadoop.hive ql.metadata.formatting. JsonMetadataFormatter	Format table and index information for machine readability using json.

Class	Description
org.apache.hadoop.hive.ql.metadata.formatting. MetaFormatUtils	This class provides methods to format table and index information.
org.apache.hadoop.hive.ql.optimizer. BucketMapJoinOptimizer	this transformation does bucket map join optimization.
org.apache.hadoop.hive.ql.optimizer. BucketingSortingReduceSinkOptimizer	This transformation does optimization for enforcing bucketing and sorting.
org.apache.hadoop.hive.ql.optimizer. ColumnPruner	Implementation of one of the rule-based optimization steps.
org.apache.hadoop.hive.ql.optimizer. ColumnPrunerProcCtx	This class implements the processor context for Column Pruner.
org.apache.hadoop.hive.ql.optimizer. ColumnPrunerProcFactory	Factory for generating the different node processors used by ColumnPruner.
org.apache.hadoop.hive.ql.optimizer. ConstantPropagate	Implementation of one of the rule-based optimization steps.
org.apache.hadoop.hive.ql.optimizer. ConstantPropagateProcCtx	Implements the processor context for Constant Propagate.
org.apache.hadoop.hive.ql.optimizer. ConstantPropagateProcFactory	Factory for generating the different node processors used by ConstantPropagate.
org.apache.hadoop.hive.ql.optimizer. ConvertJoinMapJoin	ConvertJoinMapJoin is an optimization that replaces a common join (aka shuffle join) with a map join (aka broadcast or fragment replicate join when possible).
org.apache.hadoop.hive.ql.optimizer. GenMRProcContext	Processor Context for creating map reduce task.
org.apache.hadoop.hive.ql.optimizer. GenMapRedUtils	General utility common functions for the Processor to convert operator into map-reduce tasks.
org.apache.hadoop.hive.ql.optimizer. GlobalLimitOptimizer	This optimizer is used to reduce the input size for the query for queries which are specifying a limit.
org.apache.hadoop.hive.ql.optimizer. GroupByOptimizer	This transformation does group by optimization.
org.apache.hadoop.hive.ql.optimizer. IdentityProjectRemover	This optimization tries to remove SelectOperator from tree which don't do any processing except forwarding columns from its parent to its children.
org.apache.hadoop.hive.ql.optimizer. JoinReorder	Implementation of rule-based join table reordering optimization.
org.apache.hadoop.hive.ql.optimizer. LimitPushdownOptimizer	Make RS calculate top-K selection for limit clause.
org.apache.hadoop.hive.ql.optimizer. MapJoinProcessor	Implementation of one of the rule-based map join optimization.
org.apache.hadoop.hive.ql.optimizer. NonBlockingOpDeDupProc	Merges SEL-SEL or FIL-FIL into single operator
org.apache.hadoop.hive.ql.optimizer. ReduceSinkMapJoinProc	This processor addresses the RS-MJ case that occurs in Tez on the small/hash table. The work that RS will be a part of must be connected to the MJ work via a broadcast edge.
org.apache.hadoop.hive.ql.optimizer. SamplePruner	The transformation step that does sample pruning.
org.apache.hadoop.hive.ql.optimizer. SimpleFetchAggregation	Execute final aggregation stage for simple fetch query on fetch task.

Class	Description
org.apache.hadoop.hive.ql.optimizer. SimpleFetchOptimizer	Tries to convert simple fetch query to single fetch task, which fetches rows directly from location of table/partition.
org.apache.hadoop.hive.ql.optimizer. SkewJoinOptimizer	SkewJoinOptimizer.
org.apache.hadoop.hive.ql.optimizer. SortedDynPartitionOptimizer	When dynamic partitioning (with or without bucketing and sorting) is enabled, this optimization sorts the records on partition, bucket and sort columns respectively before inserting records into the destination table.
org.apache.hadoop.hive.ql.optimizer. SortedMergeBucketMapJoinOptimizer	Replace a bucket map join with a sorted merge map join.
org.apache.hadoop.hive.ql.optimizer. StatsOptimizer	There is a set of queries which can be answered entirely from statistics stored in metastore.
org.apache.hadoop.hive.ql.optimizer. Transform	Optimizer interface.
org.apache.hadoop.hive.ql.optimizer.calcite. HiveCalciteUtil	Generic utility functions needed for Calcite based Hive CBO.
org.apache.hadoop.hive.ql.optimizer.calcite. HiveRelOptUtil	Splits different join conditions.
org.apache.hadoop.hive.ql.optimizer.calcite. RelOptHiveTable	Class for handling all table metadata.
org.apache.hadoop.hive.ql.optimizer.calcite. TraitsUtil	Traits utilities.
org.apache.hadoop.hive.ql.optimizer.calcite.cost. HiveRelMdCost	HiveRelMdCost supplies the implementation of cost model.
org.apache.hadoop.hive.ql.optimizer.calcite.cost. HiveVolcanoPlanner	Refinement of org.apache.calcite.plan.volcano.VolcanoPlanner for Hive.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators. HiveAggregate	Describing aggregate function as relational operator.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators. HiveFilter	Describing filter function as relational operator.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators. HiveJoin	Describing join function as relational operator.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators. HiveProject	Creates a HiveProject.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators. HiveSemiJoin	Describing semi join operator as relational operator.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators. HiveTableScan	Relational expression representing a scan of a HiveDB collection.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators. HiveUnion	Describing union operator as relational operator.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. HiveFilterJoinRule	Creates a PushFilterPastJoinRule with an explicit root operand.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. HiveJoinProjectTransposeRule	Transpose rule for hive join project.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. HiveFilterSetOpTransposeRule	Creates a HiveFilterSetOpTransposeRule.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. HiveInsertExchange4JoinRule	Not an optimization rule.

Class	Description
org.apache.hadoop.hive ql.optimizer.calcite.rules.HiveJoinAddNotNullRule	Creates an HiveJoinAddNotNullRule.
org.apache.hadoop.hive ql.optimizer.calcite.rules.HiveJoinPushTransitivePredicatesRule	Planner rule that infers predicates from on a org.apache.calcite.rel.core.Join and creates org.apache.calcite.rel.core.Filters if those predicates can be pushed to its inputs.
org.apache.hadoop.hive ql.optimizer.calcite.rules.HiveJoinToMultiJoinRule	Rule that merges a join with multijoin/join children if the equi compared the same set of input columns.
org.apache.hadoop.hive ql.optimizer.calcite.rules.HivePreFilteringRule	Pull out deterministic expressions from non-deterministic and push down deterministic expressions as a separate filter.
org.apache.hadoop.hive ql.optimizer.calcite.rules.HiveProjectMergeRule	ProjectMergeRule merges a org.apache.calcite.rel.core.Project into another org.apache.calcite.rel.core.Project, provided the projects aren't projecting identical sets of input references.
org.apache.hadoop.hive ql.optimizer.calcite.rules.HiveRelFieldTrimmer	Hive relational expression field trimmer.
org.apache.hadoop.hive ql.optimizer.calcite.stats.HiveRelMdCollation	Hive relational expression metadata collation.
org.apache.hadoop.hive ql.optimizer.calcite.stats.HiveRelMdDistinctRowCount	Hive relational expression metadata.
org.apache.hadoop.hive ql.optimizer.calcite.stats.HiveRelMdDistribution	Hive relational expression metadata distribuiton.
org.apache.hadoop.hive ql.optimizer.calcite.stats.HiveRelMdMemory	Hive relational expression metadata memory
org.apache.hadoop.hive ql.optimizer.calcite.stats.HiveRelMdParallelism	Hive relational expression metadata parallelism.
org.apache.hadoop.hive ql.optimizer.calcite.stats.HiveRelMdRowCount	Hive relational expression metadata row count.
org.apache.hadoop.hive ql.optimizer.calcite.stats.HiveRelMdSelectivity	Hive relational expression metadata selectivity.
org.apache.hadoop.hive ql.optimizer.calcite.stats.HiveRelMdSize	Hive relational expression metadata size.
org.apache.hadoop.hive ql.optimizer.calcite.stats.HiveRelMdUniqueKeys	Hive relational expression metadata unique keys.
org.apache.hadoop.hive ql.optimizer.calcite.translator.ASTConverter	Abstract syntax tree converter.
org.apache.hadoop.hive ql.optimizer.calcite.translator.ExpressionNodeConverter	Expression node converter.
org.apache.hadoop.hive ql.optimizer.calcite.translator.HiveOpConverter	Hive operation converter.
org.apache.hadoop.hive ql.optimizer.calcite.translator.HiveOpConverterPostProc	Post processing hive operation converter.
org.apache.hadoop.hive ql.optimizer.calcite.translator.PlanModifierForASTConv	Modifying plan for converting abstract syntax tree.
org.apache.hadoop.hive ql.optimizer.calcite.translator.PlanModifierForReturnPath	Modifying plan for operation tree.

Class	Description
org.apache.hadoop.hive.ql.optimizer.calcite.translator. RexNodeConverter	Row expression node converter.
org.apache.hadoop.hive.ql.optimizer.calcite.translator. SqlFunctionConverter	Converting SQL function.
org.apache.hadoop.hive.ql.optimizer.correlation. CorrelationOptimizer	Implementation of Correlation Optimizer.
org.apache.hadoop.hive.ql.optimizer.correlation. CorrelationUtilities	Utilities for both CorrelationOptimizer and ReduceSinkDeDuplication.
org.apache.hadoop.hive.ql.optimizer.correlation. ReduceSinkDeDuplication	If two reducer sink operators share the same partition/sort columns and order, they can be merged.
org.apache.hadoop.hive.ql.optimizer.index. RewriteGBUsingIndex	RewriteGBUsingIndex is implemented as one of the Rule-based Optimizations.
org.apache.hadoop.hive.ql.optimizer.index. RewriteParseContextGenerator	RewriteParseContextGenerator is a class that offers methods to generate operator tree for input queries.
org.apache.hadoop.hive.ql.optimizer.lineage. ExprProcFactory	Expression processor factory for lineage.
org.apache.hadoop.hive.ql.optimizer.lineage. Generator	Generates the lineage information for the columns and tables from the plan before it goes through other optimization phases.
org.apache.hadoop.hive.ql.optimizer.lineage. LineageCtx	Contains the lineage context that is passed while walking the operator tree in Lineage.
org.apache.hadoop.hive.ql.optimizer.lineage. OpProcFactory	Operator factory for the rule processors for lineage.
org.apache.hadoop.hive.ql.optimizer.listbucketingpruner. ListBucketingPruner	The transformation step that does list bucketing pruning.
org.apache.hadoop.hive.ql.optimizer.metainfo.annotation. AnnotateWithOpTraits	This class annotates each operator with its traits. The OpTraits class specifies the traits that are populated for each operator.
org.apache.hadoop.hive.ql.optimizer.pcr. PartitionConditionRemover	The transformation step that does partition condition remover.
org.apache.hadoop.hive.ql.optimizer.pcr. PcrExprProcFactory	Expression processor factory for partition condition removing.
org.apache.hadoop.hive.ql.optimizer.physical. CrossProductCheck	Check each MapJoin and ShuffleJoin Operator to see they are performing a cross product.
org.apache.hadoop.hive.ql.optimizer.physical. Vectorizer	Class to define vectorization.
org.apache.hadoop.hive.ql.optimizer.ppr. PartitionExpressionProxyForMetastore	The basic implementation of PartitionExpressionProxy that uses ql package classes.
org.apache.hadoop.hive.ql.optimizer.ppr. PartitionPruner	The transformation step that does partition pruning.
org.apache.hadoop.hive.ql.optimizer.spark. SparkReduceSinkMapJoinProc	This processor addresses the RS-MJ case that occurs in spark on the small/hash table side of things. The work that RS will be a part of must be connected to the MJ work via be a broadcast edge.
org.apache.hadoop.hive.ql.optimizer.stats.annotation. AnnotateWithStatistics	Create a list of top op nodes
org.apache.hadoop.hive.ql.optimizer.unionproc. UnionProcessor	FileSinkProcessor is a simple rule to remember seen unions for later processing.
org.apache.hadoop.hive.ql.parse. ASTNode	Definition of abstract syntax tree node.

Class	Description
org.apache.hadoop.hive.ql.parse. BaseSemanticAnalyzer	BaseSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse. CalcitePlanner	Cost based optimizer planner.
org.apache.hadoop.hive.ql.parse. ColumnAccessAnalyzer	Analysis of column access.
org.apache.hadoop.hive.ql.parse. ColumnStatsSemanticAnalyzer	ColumnStatsSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse. DDLSemanticAnalyzer	DDLSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse. ExplainSQRewriteSemanticAnalyzer	ExplainSQRewriteSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse. ExplainSemanticAnalyzer	ExplainSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse. ExportSemanticAnalyzer	ExportSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse. FunctionSemanticAnalyzer	FunctionSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse. GenTezProcContext	GenTezProcContext.
org.apache.hadoop.hive.ql.parse. GenTezUtils	GenTezUtils is a collection of shared helper methods to produce TezWork.
org.apache.hadoop.hive.ql.parse. GlobalLimitCtx	context for pruning inputs.
org.apache.hadoop.hive.ql.parse. ImportSemanticAnalyzer	ImportSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse. LoadSemanticAnalyzer	LoadSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse. MacroSemanticAnalyzer	MacroSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse. MapReduceCompiler	Compiling list of tasks.
org.apache.hadoop.hive.ql.parse. MetadataExportListener	Listens for drop events and, if set, exports the table's metadata as JSON to the trash of the user performing the drop
org.apache.hadoop.hive.ql.parse. ParseContext	Parse Context: The current parse context.
org.apache.hadoop.hive.ql.parse. ParseDriver	ParseDriver.
org.apache.hadoop.hive.ql.parse. ParseUtils	Library of utility functions used in the parse code.
org.apache.hadoop.hive.ql.parse. QB	Implementation of the query block.
org.apache.hadoop.hive.ql.parse. QBParseInfo	Implementation of the parse information related to a query block.
org.apache.hadoop.hive.ql.parse. RowResolver	Implementation of the Row Resolver.
org.apache.hadoop.hive.ql.parse. SemanticAnalyzer	Implementation of the semantic analyzer.
org.apache.hadoop.hive.ql.parse. SemanticAnalyzerFactory	SemanticAnalyzerFactory.
org.apache.hadoop.hive.ql.parse. SplitSample	Stores all the information specified in the TABLESAMPLE(...) clause.
org.apache.hadoop.hive.ql.parse. TaskCompiler	TaskCompiler is a the base class for classes that compile operator pipelines into tasks.
org.apache.hadoop.hive.ql.parse. TezCompiler	TezCompiler translates the operator plan into TezTasks.

Class	Description
org.apache.hadoop.hive.ql.parse. TypeCheckCtx	This class implements the context information that is used for typechecking phase in query compilation.
org.apache.hadoop.hive.ql.parse. TypeCheckProcFactory	The Factory for creating typecheck processors.
org.apache.hadoop.hive.ql.parse. UpdateDeleteSemanticAnalyzer	A subclass of the org.apache.hadoop.hive.ql.parse.SemanticAnalyzer that just handles update and delete statements.
org.apache.hadoop.hive.ql.parse. WindowingSpec	Windowing Specification.
org.apache.hadoop.hive.ql.parse.spark. GenSparkProcContext	GenSparkProcContext maintains information about the tasks and operators as we walk the operator tree to break them into SparkTasks.
org.apache.hadoop.hive.ql.parse.spark. GenSparkUtils	GenSparkUtils is a collection of shared helper methods to produce SparkWork Cloned from GenTezUtils.
org.apache.hadoop.hive.ql.parse.spark. GenSparkWorkWalker	Walks the operator tree in DFS fashion.
org.apache.hadoop.hive.ql.parse.spark. OptimizeSparkProcContext	OptimizeSparkProcContext.
org.apache.hadoop.hive.ql.plan. AbstractOperatorDesc	Operator description.
org.apache.hadoop.hive.ql.plan. AlterTableDesc	AlterTableDesc.
org.apache.hadoop.hive.ql.plan. AlterTableSimpleDesc	Contains information needed to modify a partition or a table
org.apache.hadoop.hive.ql.plan. BaseWork	BaseWork.
org.apache.hadoop.hive.ql.plan. ColumnStatsDesc	Contains the information needed to persist column level statistics
org.apache.hadoop.hive.ql.plan. ColumnStatsWork	ColumnStats Work.
org.apache.hadoop.hive.ql.plan. CommonMergeJoinDesc	Description of merge join operator.
org.apache.hadoop.hive.ql.plan. CreateTableDesc	CreateTableDesc.
org.apache.hadoop.hive.ql.plan. CreateViewDesc	CreateViewDesc.
org.apache.hadoop.hive.ql.plan. DDLWork	DDLWork.
org.apache.hadoop.hive.ql.plan. DropTableDesc	DropTableDesc.
org.apache.hadoop.hive.ql.plan. DynamicPartitionCtx	Dynamic partition context.
org.apache.hadoop.hive.ql.plan. DynamicPruningEventDesc	Dynamic pruning event description.
org.apache.hadoop.hive.ql.plan. ExplainWork	ExplainWork.
org.apache.hadoop.hive.ql.plan. ExprNodeDesc	ExprNodeDesc.
org.apache.hadoop.hive.ql.plan. ExprNodeDescUtils	Utilities for expression node description.
org.apache.hadoop.hive.ql.plan. FetchWork	FetchWork.
org.apache.hadoop.hive.ql.plan. FileSinkDesc	FileSinkDesc.
org.apache.hadoop.hive.ql.plan. FilterDesc	FilterDesc.
org.apache.hadoop.hive.ql.plan. GroupByDesc	GroupByDesc.
org.apache.hadoop.hive.ql.plan. HashTableSinkDesc	Map Join operator Descriptor implementation.
org.apache.hadoop.hive.ql.plan. JoinCondDesc	Join conditions Descriptor implementation.

Class	Description
org.apache.hadoop.hive.ql.plan. JoinDesc	Join operator Descriptor implementation.
org.apache.hadoop.hive.ql.plan. LateralViewJoinDesc	LateralViewJoinDesc.
org.apache.hadoop.hive.ql.plan. LimitDesc	LimitDesc.
org.apache.hadoop.hive.ql.plan. LoadTableDesc	LoadTableDesc.
org.apache.hadoop.hive.ql.plan. MapJoinDesc	Map Join operator Descriptor implementation.
org.apache.hadoop.hive.ql.plan. MapWork	MapWork represents all the information used to run a map task on the cluster.
org.apache.hadoop.hive.ql.plan. MapredWork	MapredWork.
org.apache.hadoop.hive.ql.plan. MergeJoinWork	Creating merge join work.
org.apache.hadoop.hive.ql.plan. PartitionDesc	PartitionDesc.
org.apache.hadoop.hive.ql.plan. PlanUtils	PlanUtils.
org.apache.hadoop.hive.ql.plan. ReduceSinkDesc	ReduceSinkDesc.
org.apache.hadoop.hive.ql.plan. ReduceWork	ReduceWork represents all the information used to run a reduce task on the cluster.
org.apache.hadoop.hive.ql.plan. SelectDesc	SelectDesc.
org.apache.hadoop.hive.ql.plan. SparkHashTableSinkDesc	Map Join operator Descriptor implementation.
org.apache.hadoop.hive.ql.plan. Statistics	Statistics.
org.apache.hadoop.hive.ql.plan. StatsWork	ConditionalStats.
org.apache.hadoop.hive.ql.plan. TableScanDesc	Table Scan Descriptor Currently, data is only read from a base source as part of map-reduce framework.
org.apache.hadoop.hive.ql.plan. TezWork	TezWork.
org.apache.hadoop.hive.ql.plan. UnionWork	Simple wrapper for union all cases.
org.apache.hadoop.hive.ql.plan. VectorGroupByDesc	VectorGroupByDesc.
org.apache.hadoop.hive.ql.plan.ptf. BoundaryDef	Map-reduce boundaries definition.
org.apache.hadoop.hive.ql.plan.ptf. CurrentRowDef	Current row definition.
org.apache.hadoop.hive.ql.plan.ptf. OrderExpressionDef	Order expression definition.
org.apache.hadoop.hive.ql.plan.ptf. RangeBoundaryDef	Range boundary definition.
org.apache.hadoop.hive.ql.plan.ptf. ValueBoundaryDef	Value boundary definition.
org.apache.hadoop.hive.ql.plan.ptf. WindowFrameDef	Window frame definition.
org.apache.hadoop.hive.ql.ppd. ExprWalkerInfo	Context for Expression Walker for determining predicate pushdown candidates It contains a ExprInfo object for each expression that is processed.
org.apache.hadoop.hive.ql.ppd. OpProcFactory	Operator factory for predicate pushdown processing of operator graph Each operator determines the pushdown predicates by walking the expression tree.
org.apache.hadoop.hive.ql.ppd. PredicatePushDown	Implements predicate pushdown.
org.apache.hadoop.hive.ql.ppd. PredicateTransitivePropagate	Propagates filters to other aliases based on join condition
org.apache.hadoop.hive.ql.ppd. SyntheticJoinPredicate	Creates synthetic predicates that represent "IN (keylist other table)"

Class	Description
org.apache.hadoop.hive.ql.processors. AddResourceProcessor	AddResourceProcessor.
org.apache.hadoop.hive.ql.processors. CommandProcessorResponse	Encapsulates the basic response info returned by classes the implement the CommandProcessor interface.
org.apache.hadoop.hive.ql.processors. CompileProcessor	Processor allows users to build code inside a hive session, then use this code as a UDF, Serde, or even a more complex entity like an input format or hook.
org.apache.hadoop.hive.ql.processors. CryptoProcessor	Processes HADOOP commands used for HDFS encryption.
org.apache.hadoop.hive.ql.processors. DeleteResourceProcessor	DeleteResourceProcessor.
org.apache.hadoop.hive.ql.processors. DfsProcessor	DfsProcessor.
org.apache.hadoop.hive.ql.processors. SetProcessor	SetProcessor.
org.apache.hadoop.hive.ql.security.authorization. AuthorizationPreEventListener	AuthorizationPreEventListener : A MetaStorePreEventListener that performs authorization/authentication checks on the metastore-side.
org.apache.hadoop.hive.ql.security.authorization. AuthorizationUtils	Utility code shared by hive internal code and sql standard authorization plugin implementation
org.apache.hadoop.hive.ql.security.authorization. HiveAuthorizationProviderBase	Class for authorization that returns userNames and groupNames.
org.apache.hadoop.hive.ql.security.authorization.plugin. AuthorizationMetaStoreFilterHook	Metastore filter hook for filtering out the list of objects that the current authorization implementation does not allow user to see
org.apache.hadoop.hive.ql.security.authorization.plugin. HiveAuthorizerImpl	Convenience implementation of HiveAuthorizer.
org.apache.hadoop.hive.ql.security.authorization.plugin. HiveAuthzContext	Provides context information in authorization check call that can be used for auditing and/or authorization.
org.apache.hadoop.hive.ql.security.authorization.plugin. HivePrivilegeObject	Represents the object on which privilege is being granted/revoked, and objects being used in queries.
org.apache.hadoop.hive.ql.security.authorization.plugin. HiveV1Authorizer	Hive v1 authorization class.
org.apache.hadoop.hive.ql.security.authorization.plugin.sqlstd. DummyHiveAuthorizationValidator	A no-op HiveAuthorizationValidator for use from hive cli.
org.apache.hadoop.hive.ql.security.authorization.plugin.sqlstd. SQLAuthorizationUtils	Utilities for SQL based authorization.
org.apache.hadoop.hive.ql.security.authorization.plugin.sqlstd. SQLStdHiveAccessController	Implements functionality of access control statements for sql standard based authorization
org.apache.hadoop.hive.ql.security.authorization.plugin.sqlstd. SQLStdHiveAuthorizationValidator	Class to check if user has privileges to perform certain action according to SQL standart hive authorization.
org.apache.hadoop.hive.ql.session. LineageState	LineageState.
org.apache.hadoop.hive.ql.session. OperationLog	OperationLog wraps the actual operation log file, and provides interface for accessing, reading, writing, and removing the file.
org.apache.hadoop.hive.ql.session. SessionState	SessionState encapsulates common data associated with a session.

Class	Description
org.apache.hadoop.hive.ql.stats. StatsFactory	A factory of stats publisher and aggregator implementations of the StatsPublisher and StatsAggregator interfaces.
org.apache.hadoop.hive.ql.stats. StatsUtils	Utilities of stats publisher and aggregator.
org.apache.hadoop.hive.ql.stats.fs. FSStatsAggregator	File system stats aggregator.
org.apache.hadoop.hive.ql.stats.fs. FSStatsPublisher	File system stats publisher.
org.apache.hadoop.hive.ql.txn.compactor. CompactorMR	Performs compactions via an MR job.
org.apache.hadoop.hive.ql.txn.compactor. Worker	Performs compactions.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFAverage	GenericUDFAverage.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFStreamingEvaluator	User defined aggregate function streaming evaluator.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFSum	GenericUDFSum.
org.apache.hadoop.hive.ql.udf.generic. GenericUDF	A Generic User-defined function (GenericUDF) for the use with Hive.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFBasePad	A Generic User-defined function (GenericUDF) for the use with Hive.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFBridge	GenericUDFBridge encapsulates UDF to provide the same interface as GenericUDF.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFDateAdd	UDFDateAdd.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFDateSub	UDFDateSub.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFFromUtcTimestamp	Generic user defined function to compute UTC timestamp.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFGreatest	GenericUDF Class for SQL construct "greatest(v1, v2, ..
org.apache.hadoop.hive.ql.udf.generic. GenericUDFLeast	GenericUDF Class for SQL construct "least(v1, v2, ..
org.apache.hadoop.hive.ql.udf.generic. GenericUDFLpad	UDFLpad.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFOPAnd	GenericUDF Class for computing and.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFOPEqual	GenericUDF Class for operation EQUAL.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFOPEqualOrGreaterThan	GenericUDF Class for operation EqualOrGreaterThan.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFOPEqualOrLessThan	GenericUDF Class for operation EqualOrLessThan.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFOPGreaterThan	GenericUDF Class for operation GreaterThan.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFOPLessThan	GenericUDF Class for operation LessThan.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFOPNotEqual	GenericUDF Class for operation Not EQUAL.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFOPNotNull	GenericUDFOPNotNull.

Class	Description
org.apache.hadoop.hive.ql.udf.generic. GenericUDFOPNull	GenericUDFOPNull.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFOPor	GenericUDF Class for computing or.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFRound	Rounding function permits rounding off integer digits in decimal numbers, which essentially downgrades the scale to negative territory.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFRpad	UDFRpad.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFToUnixTimeStamp	Deterministic version of UDFUnixTimeStamp.
org.apache.hadoop.hive.ql.udf.generic. GenericUDFUtils	Util functions for GenericUDF classes.
org.apache.hadoop.hive.ql.udf.generic. NumDistinctValueEstimator	Take the average of the index for all the bit vectors and get the estimated NDV (estimateNumDistinctValues).
org.apache.hadoop.hive.ql.udf.generic. NumericHistogram	A generic, re-usable histogram class that supports partial aggregations.
org.apache.hadoop.hive.ql.udf.generic. RoundUtils	Utility class for generic round UDF.
org.apache.hadoop.hive.ql.udf.ptf. WindowingTableFunction	A window function performs a calculation across a set of table rows that are somehow related to the current row.
org.apache.hadoop.hive.ql.util. DateTimeMath	Operations involving/returning year-month intervals.
org.apache.hadoop.hive.ql.util. DosToUnix	Converting windows script to UNIX.
org.apache.hadoop.hive.ql.util. ZooKeeperHiveHelper	Get the ensemble server addresses from the configuration. The format is: host1:port,host2:port
org.apache.hadoop.hive.serde2. AbstractSerDe	Abstract class for implementing SerDe.
org.apache.hadoop.hive.serde2. ColumnProjectionUtils	ColumnProjectionUtils.
org.apache.hadoop.hive.serde2. DelimitedJSONSerDe	DelimitedJSONSerDe.
org.apache.hadoop.hive.serde2. MetadataTypedColumnsetSerDe	MetadataTypedColumnsetSerDe.
org.apache.hadoop.hive.serde2. OpenCSVSerde	OpenCSVSerde use opencsv to deserialize CSV format.
org.apache.hadoop.hive.serde2. RegexSerDe	RegexSerDe uses regular expression (regex) to deserialize data.
org.apache.hadoop.hive.serde2. SerDeUtils	SerDeUtils.
org.apache.hadoop.hive.serde2. WriteBuffers	The structure storing arbitrary amount of data as a set of fixed-size byte buffers.
org.apache.hadoop.hive.serde2.avro. AvroLazyObjectInspector	Lazy objectinspector for avro serialization
org.apache.hadoop.hive.serde2.avro. AvroSerDe	Read or write Avro data from Hive.
org.apache.hadoop.hive.serde2.avro. AvroSerDeUtils	Utilities useful only to the AvroSerDe itself.
org.apache.hadoop.hive.serde2.binarysortable. BinarySortableSerDe	BinarySortableSerDe can be used to write data in a way that the data can be compared byte-by-byte with the same order.
org.apache.hadoop.hive.serde2.binarysortable.fast. BinarySortableDeserializeRead	Directly deserialize with the caller reading field-by-field the LazyBinary serialization format.
org.apache.hadoop.hive.serde2.binarysortable.fast. BinarySortableSerializeWrite	Directly serialize, field-by-field, the BinarySortable format.

Class	Description
org.apache.hadoop.hive.serde2.io. DateWritable	DateWritable Writable equivalent of java.sql.Date.
org.apache.hadoop.hive.serde2.io. HiveDecimalWritable	Get a HiveDecimal instance from the writable and constraint it with maximum precision/scale.
org.apache.hadoop.hive.serde2.io. TimestampWritable	TimestampWritable Writable equivalent of java.sql.Timestamp Timestamps are of the format YYYY-MM-DD HH:MM:SS.[fff...] We encode Unix timestamp in seconds in 4 bytes, using the MSB to signify whether the timestamp has a fractional portion.
org.apache.hadoop.hive.serde2.lazy. LazyBinary	LazyBinary stores a binary object in a LazyObject.
org.apache.hadoop.hive.serde2.lazy. LazyHiveDecimal	LazyHiveDecimal stores hive decimal object in LazyObject.
org.apache.hadoop.hive.serde2.lazy. LazyMap	LazyMap stores a map of Primitive LazyObjects to LazyObjects.
org.apache.hadoop.hive.serde2.lazy. LazySerDeParameters	SerDeParameters.
org.apache.hadoop.hive.serde2.lazy. LazySimpleSerDe	LazySimpleSerDe can be used to read the same data format as MetadataTypedColumnsetSerDe and TCTLSeparatedProtocol.
org.apache.hadoop.hive.serde2.lazy. LazyUtils	LazyUtils.
org.apache.hadoop.hive.serde2.lazy.fast. LazySimpleDeserializeRead	Directly deserialize with the caller reading field-by-field the LazySimple (text) serialization format.
org.apache.hadoop.hive.serde2.lazy.fast. LazySimpleSerializeWrite	Directly serialize, field-by-field, the LazyBinary format.
org.apache.hadoop.hive.serde2.lazy.objectinspector. LazyListObjectInspector	LazyListObjectInspector works on array data that is stored in LazyArray.
org.apache.hadoop.hive.serde2.lazy.objectinspector. LazyMapObjectInspector	LazyMapObjectInspector works on struct data that is stored in LazyStruct.
org.apache.hadoop.hive.serde2.lazy.objectinspector. LazyUnionObjectInspector	LazyUnionObjectInspector works on union data that is stored in LazyUnion.
org.apache.hadoop.hive.serde2.lazybinary. LazyBinarySerDe	The LazyBinarySerDe class combines the lazy property of LazySimpleSerDe class and the binary property of BinarySortable class.
org.apache.hadoop.hive.serde2.lazybinary.fast. LazyBinaryDeserializeRead	Directly deserialize with the caller reading field-by-field the LazyBinary serialization format.
org.apache.hadoop.hive.serde2.lazybinary.fast. LazyBinarySerializeWrite	Directly serialize, field-by-field, the LazyBinary format.
org.apache.hadoop.hive.serde2.objectinspector. ObjectInspectorFactory	ObjectInspectorFactory is the primary way to create new ObjectInspector instances.
org.apache.hadoop.hive.serde2.objectinspector. ObjectInspectorUtils	ObjectInspectorFactory is the primary way to create new ObjectInspector instances.
org.apache.hadoop.hive.serde2.objectinspector. ReflectionStructObjectInspector	ReflectionStructObjectInspector works on struct data that is stored as a native Java object.
org.apache.hadoop.hive.serde2.objectinspector. SettableUnionObjectInspector	SettableUnionObjectInspector.
org.apache.hadoop.hive.serde2.objectinspector. StandardStructObjectInspector	ListStructObjectInspector works on struct data that is stored as a Java List or Java Array object.

Class	Description
org.apache.hadoop.hive.serde2.objectinspector. StandardUnionObjectInspector	StandardUnionObjectInspector works on union data that is stored as UnionObject.
org.apache.hadoop.hive.serde2.objectinspector. ThriftUnionObjectInspector	Always use the ObjectInspectorFactory to create new ObjectInspector objects, instead of directly creating an instance of this class.
org.apache.hadoop.hive.serde2.typeinfo. HiveDecimalUtils	Utilities for decimal precision and scale.
org.apache.hadoop.hive.serde2.typeinfo. TypeInfoUtils	TypeInfoUtils.
org.apache.hadoop.hive.shims. Hadoop23Shims	Implementation of shims against Hadoop 0.23.0.
org.apache.hadoop.hive.shims. HadoopShimsSecure	Base implementation for shims against secure Hadoop 0.20.3/0.23.
org.apache.hadoop.hive.shims. ShimLoader	ShimLoader.
org.apache.hadoop.hive.shims. Utils	Utilities for split location provider.
org.apache.hadoop.hive.thrift. DelegationTokenSecretManager	A Hive specific delegation token secret manager.
org.apache.hadoop.hive.thrift. HadoopThriftAuthBridge	Functions that bridge Thrift's SASL transports to Hadoop's SASL callback handlers and authentication classes.
org.apache.hadoop.hive.thrift. TokenStoreDelegationTokenSecretManager	Extension of DelegationTokenSecretManager to support alternative to default in-memory token management for fail-over and clustering through plug-able token store (ZooKeeper etc.).
org.apache.hive.beeline. BeeLine	A console SQL shell with command completion.
org.apache.hive.beeline. Commands	Implementation of beeline commands.
org.apache.hive.common.util. BloomFilter	BloomFilter is a probabilistic data structure for set membership check.
org.apache.hive.common.util. DateUtils	DateUtils.
org.apache.hive.common.util. HiveStringUtils	HiveStringUtils General string utils Originally copied from o.a.hadoop.util.StringUtils
org.apache.hive.common.util. HiveTestUtils	Utilities for testing hive.
org.apache.hive.common.util. Murmur3	Murmur3 is successor to Murmur2 fast non-cryptographic hash algorithms.
org.apache.hive.common.util. ShutdownHookManager	The ShutdownHookManager enables running shutdownHook in a deterministic order, higher priority first.
org.apache.hive.common.util. StreamPrinter	StreamPrinter.
org.apache.hive.hcatalog.cli. HCatCli	HCatalog command line interface.
org.apache.hive.hcatalog.common. HCatConstants	List of constants used by HCatalog.
org.apache.hive.hcatalog.streaming. ConnectionError	Exception to catch connection errors.
org.apache.hive.hcatalog.streaming. DelimitedInputWriter	Streaming Writer handles delimited input (eg.
org.apache.hive.hcatalog.streaming. HiveEndPoint	Information about the hive end point (i.e.
org.apache.hive.hcatalog.streaming. InvalidTable	Exception to catch invalid table.
org.apache.hive.hcatalog.streaming. StrictJsonWriter	Streaming Writer handles utf8 encoded Json (Strict syntax).

Class	Description
org.apache.hive.hcatalog.templeton. AppConfig	The configuration for Templeton.
org.apache.hive.hcatalog.templeton. Main	The main executable that starts up and runs the Server.
org.apache.hive.jdbc .HiveConnection	HiveConnection.
org.apache.hive.jdbc .HiveDatabaseMetaData	HiveDatabaseMetaData.
org.apache.hive.jdbc .HivePreparedStatement	HivePreparedStatement.
org.apache.hive.jdbc .HiveQueryResultSet	HiveQueryResultSet.
org.apache.hive.jdbc .HiveStatement	HiveStatement.
org.apache.hive.jdbc .JdbcColumn	Column metadata.
org.apache.hive.jdbc .Utils	Utilities for jdbc.
org.apache.hive.service. ServiceUtils	Utilities to correctly process domain names etc.
org.apache.hive.service.auth. AuthenticationProviderFactory	Helps select a PasswdAuthenticationProvider for a given {@code AuthMethod}.
org.apache.hive.service.auth. HiveAuthFactory	Helps in some aspects of authentication.
org.apache.hive.service.auth. LdapAuthenticationProviderImpl	Utilities to correctly process domain names etc.
org.apache.hive.service.auth. TSetIpAddressProcessor	Sets the ipAddress for operations executed via HiveServer2.
org.apache.hive.service.cli. CLIService	CLIService.
org.apache.hive.service.cli. CLIServiceUtils	CLIServiceUtils.
org.apache.hive.service.cli. ColumnBasedSet	ColumnBasedSet.
org.apache.hive.service.cli. ColumnDescriptor	ColumnDescriptor.
org.apache.hive.service.cli. ColumnValue	Protocols before HIVE_CLI_SERVICE_PROTOCOL_V6 (used by RowBasedSet)
org.apache.hive.service.cli. EmbeddedCLIServiceClient	Embedded CLI Service Client.
org.apache.hive.service.cli. FetchOrientation	Fetch Orientation.
org.apache.hive.service.cli. GetInfoType	Get Info type.
org.apache.hive.service.cli. GetInfoValue	Get Info value.
org.apache.hive.service.cli. Handle	Handle.
org.apache.hive.service.cli. HandleIdentifier	Handle identifier.
org.apache.hive.service.cli. HiveSQLException	Hive SQL exception.

Class	Description
org.apache.hive.service.cli. OperationHandle	Handler for operation.
org.apache.hive.service.cli. OperationState	Operation State.
org.apache.hive.service.cli. OperationStatus	Operation Status.
org.apache.hive.service.cli. OperationType	OperationType.
org.apache.hive.service.cli. RowBasedSet	Row Based Set.
org.apache.hive.service.cli. RowSetFactory	Row set factory class.
org.apache.hive.service.cli. SessionHandle	Session Handle.
org.apache.hive.service.cli. TableSchema	Table Schema.
org.apache.hive.service.cli. TypeDescriptor	Type Descriptor.
org.apache.hive.service.cli. TypeQualifiers	Holds type qualifier information for a primitive type, such as char/varchar length or decimal precision/scale.
org.apache.hive.service.cli.operation. ClassicTableTypeMapping	Classic Table Type Mapping.
org.apache.hive.service.cli.operation. ExecuteStatementOperation	Implementation of statement execution.
org.apache.hive.service.cli.operation. HiveCommandOperation	Executes a HiveCommand.
org.apache.hive.service.cli.operation. HiveTableTypeMapping	Hive Table Type Mapping.
org.apache.hive.service.cli.operation. LogDivertAppender	Divert appender to redirect operation logs to separate files.
org.apache.hive.service.cli.operation. MetadataOperation	Metadata Operation.
org.apache.hive.service.cli.operation. Operation	Class to define operation.
org.apache.hive.service.cli.operation. OperationManager	Operation Manager.
org.apache.hive.service.cli.operation. SQLOperation	SQL Operation.
org.apache.hive.service.cli.session. HiveSessionImpl	Hive Session.
org.apache.hive.service.cli.session. HiveSessionImplwithUGI	Hive session implementation with UGI.
org.apache.hive.service.cli.session. SessionManager	Session Manager.
org.apache.hive.service.cli.thrift. ThriftBinaryCLIService	Initialize worker threads in hive CLI startup.
org.apache.hive.service.cli.thrift. ThriftCLIService	Thrift CLI Service.
org.apache.hive.service.cli.thrift. ThriftCLIServiceClient	Thrift CLI Service Client.
org.apache.hive.service.cli.thrift. ThriftHttpCLIService	Service to handle requests over HTTP.
org.apache.hive.service.cli.thrift. ThriftHttpServlet	Thrift Http servlet.
org.apache.hive.spark.client. MetricsCollection	Provides metrics collected for a submitted job.
org.apache.hive.spark.client. SparkClientUtilities	Utilities for spark client.
org.apache.hive.spark.client.rpc. Rpc	Encapsulates the RPC functionality.
org.apache.hive.spark.client.rpc. RpcConfiguration	Definitions of configuration keys and default values for the RPC layer.
org.apache.hive.spark.client.rpc. RpcServer	An RPC server.

Changed Interfaces in Hive 2.1

The following interfaces have changed in Hive 2.1:

Interface	Description
org.apache.hadoop.hive.common. ValidTxnList	Models the list of transactions that should be included in a snapshot.
org.apache.hadoop.hive.metastore. AlterHandler	Interface for Alter Table and Alter Partition code
org.apache.hadoop.hive.metastore. IMetaStoreClient	Wrapper around hive metastore thrift api
org.apache.hadoop.hive.metastore. RawStore	
org.apache.hadoop.hive.metastore. PartitionExpressionProxy	The proxy interface that metastore uses for variety of QL operations (metastore can't depend on QL because QL depends on metastore; creating metastore-client module would be a proper way to solve this problem).
org.apache.hadoop.hive ql.exec.persistence. MapJoinTableContainer	
org.apache.hadoop.hive ql.exec.spark. SparkShuffler	
org.apache.hadoop.hive ql.exec.spark. SparkTran	
org.apache.hadoop.hive ql.exec.spark.session. SparkSession	
org.apache.hadoop.hive ql.exec.spark.status. SparkJobStatus	SparkJobStatus identify what Hive want to know about the status of a Spark job.
org.apache.hadoop.hive ql.exec.vector.expressions. VectorExpressionWriter	Interface used to create Writable objects from vector expression primitives.
org.apache.hadoop.hive ql.exec.vector.mapjoin.hashtable. VectorMapJoinHashTable	
org.apache.hadoop.hive ql.io. InputFormatChecker	Check for validity of the input files.
org.apache.hadoop.hive ql.io.orc. Reader	The interface for reading ORC files.
org.apache.hadoop.hive ql.io.orc. RecordReader	A row-by-row iterator for ORC files.
org.apache.hadoop.hive ql.io.orc. Writer	The HIVE interface for writing ORC files.
org.apache.hadoop.hive ql.io.sarg. SearchArgument	Primary interface for SearchArgument , which are the subset of predicates that can be pushed down to the RecordReader.
org.apache.hadoop.hive ql.lockmgr. HiveTxnManager	An interface that allows Hive to manage transactions.
org.apache.hadoop.hive ql.metadata.formatting. MetaDateFormatter	Interface to format table and index information.
org.apache.hadoop.hive ql.plan. OperatorDesc	
org.apache.hadoop.hive ql.security.authorization.plugin. HiveAuthorizationValidator	Interface used to check if user has privileges to perform certain action.
org.apache.hadoop.hive ql.security.authorization.plugin. HiveAuthorizer	Interface for hive authorization plugins.
org.apache.hadoop.hive ql.stats. StatsAggregator	An interface for any possible implementation for gathering statistics.
org.apache.hadoop.hive ql.stats. StatsPublisher	An interface for any possible implementation for publishing statics.

Interface	Description
org.apache.hadoop.hive.shims. HadoopShims	In order to be compatible with multiple versions of Hadoop, all parts of the Hadoop interface that are not cross-version compatible are encapsulated in an implementation of this class.
org.apache.hive.hcatalog.streaming. StreamingConnection	Represents a connection to a HiveEndPoint.
org.apache.hive.hcatalog.streaming. TransactionBatch	Represents a set of Transactions returned by Hive.
org.apache.hive.service.cli. ICLIService	
org.apache.hive.service.cli. RowSet	
org.apache.hive.service.cli.operation. TableTypeMapping	
org.apache.hive.service.cli.session. HiveSession	
org.apache.hive.service.cli.session. HiveSessionBase	Methods that don't need to be executed under a doAs context are here.
org.apache.hive.spark.client. JobContext	Holds runtime information about the job execution context.
org.apache.hive.spark.client. SparkClient	Defines the API for the Spark remote client.

Removed API in Hive 2.1

The following classes and interfaces are not available with Hive 2.1:

Removed Classes

Class	Description
org.apache.hadoop.hive.common.metrics.Metrics	Metrics Subsystem - allows exposure of a number of named parameters/counters via jmx, intended to be used as a static subsystem Has a couple of primary ways it can be used: (i) Using the set and get methods to set and get named parameters (ii) Using the incrementCounter method to increment and set named parameters in one go, rather than having to make a get and then a set.
org.apache.hadoop.hive.hbase.HBaseStatsAggregator	A class that implements the StatsAggregator interface through HBase.
org.apache.hadoop.hive.hbase.HBaseStatsPublisher	A class that implements the StatsPublisher interface through HBase.
org.apache.hadoop.hive.hbase.HBaseStatsSetupConstants	HBase constants statistics setup.
org.apache.hadoop.hive.hbase.HBaseStatsUtils	Utilities for hbase statistics.
org.apache.hadoop.hive.metastore.ProtectMode	Protection Mode.
org.apache.hadoop.hive.metastore.txn.CompactionTxnHandler	Extends the transaction handler with methods needed only by the compactor threads.
org.apache.hadoop.hive.metastore.txn.TxnHandler	A handler to answer transaction related calls that come into the metastore server.
org.apache.hadoop.hive.metastore.txn.ValidCompactorTxnList	And implmentation of org.apache.hadoop.hive.common.ValidTxnList for use by the compactor.
org.apache.hadoop.hive.ql.exec.DefaultFetchFormatter	Serializes row by user specified serde and call toString() to make string type result

Class	Description
org.apache.hadoop.hive ql.exec.Heartbeater	Class to handle heartbeats for MR and Tez tasks.
org.apache.hadoop.hive ql.exec.vector.RandomRowObjectSource	Generates object inspector and random row object[].
org.apache.hadoop.hive ql.exec.vector.VectorAssignRowDynBatch	Assigns specified columns of a VectorizedRowBatch row from a Writable row Object[].
org.apache.hadoop.hive ql.exec.vector.VectorAssignRowSameBatch	Assigns specified columns of a VectorizedRowBatch row from a Writable row Object[].
org.apache.hadoop.hive ql.exec.vector.VectorSerializeRowNoNulls	Serializes columns from a row in a VectorizedRowBatch into a serialization format.
org.apache.hadoop.hive ql.exec.vector.VectorizedColumnarSerDe	VectorizedColumnarSerDe is used by Vectorized query execution engine for columnar based storage supported by RCFile.
org.apache.hadoop.hive ql.exec.vector.expressions.VectorUDFDayOfMonthLong	Expression to get day of month.
org.apache.hadoop.hive ql.exec.vector.expressions.VectorUDFHourLong	Returns hour of day.
org.apache.hadoop.hive ql.exec.vector.expressions.VectorUDFMinuteLong	Returns minute value.
org.apache.hadoop.hive ql.exec.vector.expressions.VectorUDFMonthLong	Returns month value.
org.apache.hadoop.hive ql.exec.vector.expressions.VectorUDFSecondLong	Expression to get seconds.
org.apache.hadoop.hive ql.exec.vector.expressions.VectorUDFTimestampFieldLong	Abstract class to return various fields from a Timestamp or Date.
org.apache.hadoop.hive ql.exec.vector.expressions.VectorUDFUnixTimeStampLong	Return Unix Timestamp.
org.apache.hadoop.hive ql.exec.vector.expressions.VectorUDFWeekOfYearLong	Expression to get week of year.
org.apache.hadoop.hive ql.exec.vector.expressions.VectorUDFYearLong	Expression to get year as a long.
org.apache.hadoop.hive ql.exec.vector.mapjoin.fast.VectorMapJoinFastIntHashUtil	Utilities for mapr join in vectorization mode.
org.apache.hadoop.hive ql.io.VectorizedRCFileInputFormat	A MapReduce/Hive Vectorized input format for RC files.
org.apache.hadoop.hive ql.io.VectorizedRCFileRecordReader	RCFileRecordReader.
org.apache.hadoop.hive ql.io.orc.FileDump	A tool for printing out the file structure of ORC files.
org.apache.hadoop.hive ql.io.orc.InStream	Class to define input stream.
org.apache.hadoop.hive ql.io.orc.Metadata	Metadata stored in underlying db.
org.apache.hadoop.hive ql.io.orc.MetadataReader	Class to read and process metadata.
org.apache.hadoop.hive ql.io.orc.OrcProto	Class to serialize data stored in orc.
org.apache.hadoop.hive ql.io.orc.OrcUtils	Utilities to process orc files.
org.apache.hadoop.hive ql.io.orc.RecordReaderFactory	Factory to create ORC tree readers.
org.apache.hadoop.hive ql.io.orc.RecordReaderUtils	Stateless methods shared between RecordReaderImpl and EncodedReaderImpl.

Class	Description
org.apache.hadoop.hive.ql.io.orc.StripeStatistics	Information about index data stored in stripe.
org.apache.hadoop.hive.ql.io.orc.TreeReaderFactory	Factory for creating ORC tree readers.
org.apache.hadoop.hive.ql.log.PidDailyRollingFileAppender	Logging pids in file.
org.apache.hadoop.hive.ql.optimizer.calcite.HiveConfigContext	Hive configuration context.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveLimit	Define limit operator.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveSort	Define sort operator.
org.apache.hadoop.hive.ql.parse.VariableSubstitution	The Hive variable substitution mechanism was designed to avoid some of the code that was getting baked into the scripting language on top of Hive.
org.apache.hadoop.hive.ql.session.DependencyResolver	Creating list of dependency jars.
org.apache.hadoop.hive.ql.stats.CounterStatsAggregator	Counter statistics aggregator.
org.apache.hadoop.hive.ql.stats.CounterStatsAggregatorSpark	Counter statistics aggregator for Spark.
org.apache.hadoop.hive.ql.stats.CounterStatsAggregatorTez	This class aggregates stats via counters and does so for Tez Tasks.
org.apache.hadoop.hive.ql.stats.CounterStatsPublisher	Counter statistics publisher.
org.apache.hadoop.hive.ql.udf.UDFRegExp	UDFRegExp.
org.apache.hadoop.hive.shims.Hadoop20SShims	Implementation of shims against Hadoop 0.20 with Security.
org.apache.hadoop.hive.shims.HiveEventCounter	Hive event counter.
org.apache.hadoop.hive.shims.Jetty20SShims	In order to be compatible with multiple versions of Jetty, all parts of the Jetty interface that are not cross-version compatible are encapsulated in an implementation of this class.
org.apache.hadoop.mapred.WebHCatJTShim20S	This is in org.apache.hadoop.mapred package because it relies on JobSubmissionProtocol which is package private
org.apache.hive.benchmark.vectorization.VectorizationBenchmark	Measures the performance for vectorization.
org.apache.hive.jdbc.ZooKeeperHiveClientHelper	Resolve to a host:port by connecting to ZooKeeper and picking a host randomly.
org.apache.hive.service.cli.Column	Column.
org.apache.hive.service.cli.Type	Type.
org.apache.hive.service.cli.thrift.TArrayTypeEntry	Array type entry.
org.apache.hive.service.cli.thrift.TBinaryColumn	Binary column.
org.apache.hive.service.cli.thrift.TBoolColumn	Boolean column.
org.apache.hive.service.cli.thrift.TBoolValue	Boolean value.
org.apache.hive.service.cli.thrift.TByteColumn	Byte column.
org.apache.hive.service.cli.thrift.TByteValue	Byte value.

Class	Description
org.apache.hive.service.cli.thrift.TCLIService	Command line interface service.
org.apache.hive.service.cli.thrift.TCLIServiceConstants	Command line interface constants.
org.apache.hive.service.cli.thrift.TCancelDelegationTokenReq	Cancel delegation token request.
org.apache.hive.service.cli.thrift.TCancelDelegationTokenResp	Cancel delegation token response.
org.apache.hive.service.cli.thrift.TCancelOperationReq	Cancel operation request.
org.apache.hive.service.cli.thrift.TCancelOperationResp	Cancel operation response.
org.apache.hive.service.cli.thrift.TCloseOperationReq	Close operation request.
org.apache.hive.service.cli.thrift.TCloseOperationResp	Close operation response.
org.apache.hive.service.cli.thrift.TCloseSessionReq	Close session request.
org.apache.hive.service.cli.thrift.TCloseSessionResp	Close session response.
org.apache.hive.service.cli.thrift.TColumn	Column.
org.apache.hive.service.cli.thrift.TColumnDesc	Column description.
org.apache.hive.service.cli.thrift.TColumnValue	Column value.
org.apache.hive.service.cli.thrift.TDoubleColumn	Double column.
org.apache.hive.service.cli.thrift.TDoubleValue	Double value.
org.apache.hive.service.cli.thrift.TExecuteStatementReq	Execute statement request.
org.apache.hive.service.cli.thrift.TExecuteStatementResp	Execute statement response.
org.apache.hive.service.cli.thrift.TFetchOrientation	Fetch orientation.
org.apache.hive.service.cli.thrift.TFetchResultsReq	Fetch results request.
org.apache.hive.service.cli.thrift.TFetchResultsResp	Fetch results response.
org.apache.hive.service.cli.thrift.TGetCatalogsReq	Get catalogs request.

Removed Interfaces

Interface	Description
org.apache.hadoop.hive.ql.exec. <i>FetchFormatter</i>	(For internal-use only) Used in ListSinkOperator for formatting final output
org.apache.hadoop.hive.ql.io.orc. <i>BinaryColumnStatistics</i>	Statistics for binary columns.
org.apache.hadoop.hive.ql.io.orc. <i>BooleanColumnStatistics</i>	Statistics for boolean columns.
org.apache.hadoop.hive.ql.io.orc. <i>ColumnStatistics</i>	Statistics that are available for all types of columns.
org.apache.hadoop.hive.ql.io.orc. <i>CompressionCodec</i>	Compress the in buffer to the out buffer.
org.apache.hadoop.hive.ql.io.orc. <i>CompressionCodec.Modifier</i>	Compress the in buffer to the out buffer.
org.apache.hadoop.hive.ql.io.orc. <i>ConversionTreeReaderFactory</i>	Factory for creating ORC tree readers.
org.apache.hadoop.hive.ql.io.orc. <i>DateColumnStatistics</i>	Statistics for DATE columns.

Interface	Description
org.apache.hadoop.hive.ql.io.orc.DecimalColumnStatistics	Statistics for decimal columns.
org.apache.hadoop.hive.ql.io.orc.DirectDecompressionCodec	Decompression codec.
org.apache.hadoop.hive.ql.io.orc.DoubleColumnStatistics	Statistics for float and double columns.
org.apache.hadoop.hive.ql.io.orc.IntegerColumnStatistics	Statistics for all of the integer columns, such as byte, short, int, and long.
org.apache.hadoop.hive.ql.io.orc.PositionProvider	An interface used for seeking to a row index.
org.apache.hadoop.hive.ql.io.orc.StringColumnStatistics	Statistics for string columns.
org.apache.hadoop.hive.ql.io.orc.StripeInformation	Information about the stripes in an ORC file that is provided by the Reader.
org.apache.hadoop.hive.ql.io.orc.TimestampColumnStatistics	Statistics for Timestamp columns.
org.apache.hadoop.hive.ql.stats.StatsCollectionTaskIndependent	Marker interface to differentiate between stats publisher / aggregator which don't track stats per task, as oppose to others which do.

Deprecated API in Hive 2.1

The following classes, interfaces, and fields have been deprecated in Hive 2.1.

Deprecated Classes

org.apache.hadoop.hive.ql.exec.ByteWritable
org.apache.hadoop.hive.serde.Constants
org.apache.hadoop.hive.ql.io.FlatFileInputFormat
org.apache.hadoop.hive.ql.io.FlatFileInputFormat.FlatFileRecordReader
org.apache.hadoop.hive.ql.io.IgnoreKeyTextOutputFormat use HiveIgnoreKeyTextOutputFormat instead}
org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe.SerDeParameters
org.apache.hadoop.hive.ql.exec.UDAF Either implement GenericUDAFResolver2 or extend AbstractGenericUDAFResolver instead.

Deprecated Interfaces

org.apache.hadoop.hive.serde2.Deserializer
org.apache.hadoop.hive.ql.udf.generic.GenericUDAFEvaluator.AggregationBuffer use GenericUDAFEvaluator.AbstractAggregationBuffer instead
org.apache.hadoop.hive.ql.udf.generic.GenericUDAFResolver Use GenericUDAFResolver2 instead.
org.apache.hadoop.hive.serde2.Serde
org.apache.hadoop.hive.serde2.Serializer

Deprecated Fields

org.apache.hadoop.hive.serde2.avro.AvroSerdeUtils.AVRO_SERDE_SCHEMA
org.apache.hadoop.hive.serde2.avro.AvroSerdeUtils.SCHEMA_DOC
org.apache.hadoop.hive.serde2.avro.AvroSerdeUtils.SCHEMA_LITERAL
org.apache.hadoop.hive.serde2.avro.AvroSerdeUtils.SCHEMA_NAME
org.apache.hadoop.hive.serde2.avro.AvroSerdeUtils.SCHEMA_NAMESPACE
org.apache.hadoop.hive.serde2.avro.AvroSerdeUtils.SCHEMA_RETRIEVER
org.apache.hadoop.hive.serde2.avro.AvroSerdeUtils.SCHEMA_URL
org.apache.hive.hplsql.HplsqlParser.tokenNames <i>Use HplsqlParser.VOCABULARY instead.</i>
org.apache.hive.hplsql.HplsqlLexer.tokenNames <i>Use HplsqlLexer.VOCABULARY instead.</i>

Deprecated Methods

org.apache.hadoop.hive.metastore.IMetaStoreClient.addDynamicPartitions(long, String, String, List<String>) <i>in Hive 1.3.0/2.1.0 - will be removed in 2 releases</i>
org.apache.hadoop.hive.metastore.HiveMetaStoreClient.addDynamicPartitions(long, String, String, List<String>)
org.apache.hadoop.hive.serde2.ColumnProjectionUtils.appendReadColumnIDs(Configuration, List<Integer>) <i>for backwards compatibility with <= 0.12, use appendReadColumns</i>
org.apache.hive.hcatalog.api.HCatCreateTableDesc.Builder.bucketCols(List<String>, int)
org.apache.hive.hcatalog.api.HCatCreateTableDesc.Builder.collectionItemsTerminatedBy(char)

Troubleshooting Hive and Tez

This section includes Hive and Tez troubleshooting tips.

HDFS Literal Deprecated

Starting in Hive-2.3, the `hdfs` literal is deprecated. Specifying a table location using the `hdfs` URI scheme will cause queries to fail because the Hive parser recognizes the `hdfs` literal in the `LOCATION` key word and triggers HDFS encryption, which is not supported.

If you use the `hdfs` literal with the `LOCATION` keyword in Hive queries:

```
CREATE TABLE IF NOT EXISTS i (id INT) LOCATION 'hdfs:///i';
```

The system logs the following warning:

```
LOG.warn("hdfs:// is deprecated filesystem and will be removed in future
releases. Use maprfs://
instead");
```

To avoid `hdfs` literal issues, update all instances of `hdfs` with `maprfs` in tables, partitions, and databases. Also update the `hive-site.xml` file to remove `hdfs` from the URI scheme list.

Update hive-site.xml

Remove `hdfs` from the `hive.exim.uri.scheme.whitelist` Hive configuration property in `hive-site.xml`, as shown:

```
<property>

<name>hive.exim.uri.scheme.whitelist</
name>
    <value>maprfs,...,s3</value>
</property>
```

Update Tables and Partitions

To replace the table and partition location with `maprfs`, run:

```
MariaDB [hive]> update SDS set
LOCATION = REPLACE(LOCATION, 'hdfs',
'maprfs') where LOCATION like
'%hdfs%';
```

Update Databases

To replace the database location with `maprfs`, run:

```
MariaDB [hive]> update
DBS set DB_LOCATION_URI =
REPLACE(DB_LOCATION_URI, 'hdfs',
'maprfs') where DB_LOCATION_URI like
'%hdfs%';
```

Prohibited usage of `datanucleus.schema.autoCreateAll` property

The usage of the `datanucleus.schema.autoCreateAll` property is prohibited in all cases. Instead of using this property, you must run the `schematool` command. Refer to [HIVE-21302](#) for more information.

WebHCat

Secure WebHCat operations depend on the Hive metastore having Kerberos enabled. If Kerberos is not enabled for the Hive metastore, null pointer exceptions similar to the following will appear:

```
2013-10-06 20:38:55,198 ERROR metastore.RetryingHMSHandler
(RetryingHMSHandler.java:invoke(134)) -
MetaException(message:java.lang.NullPointerException)

java.util.concurrent.ThreadPoolExecutor$Worker.runTask(ThreadPoolExecutor.ja
va:895)
    at
java.util.concurrent.ThreadPoolExecutor$Worker.run(ThreadPoolExecutor.java:9
18)
```

If you are updating to the `mapr-hive-2.3.6-mapr-1912 (EEP-6.3.0)` package, you should manually replace the old `webhcat-default.xml` configuration file with the new one and restart the WebHCat service:

```
cp /opt/mapr/hive/hive-2.3/hcatalog/etc/webhcat.new/
webhcat-default.xml /opt/mapr/hive/hive-2.3/hcatalog/etc/webhcat/
```

Hive in an Azure Cluster

When Hive services are installed on an Azure cluster, it is possible that the services will not start because Azure assigns too long (over 64 symbols) host names. Perform following steps to fix this issue:

NOTE: This issue is fixed on MapR core 6.0.1 starting from build 20180320175756.GA-1.x86_64.

1. Edit the /etc/hosts file:

```
nano /etc/hosts
```

This is an example of a /etc/hosts file for an Azure cluster:

```
127.0.0.1    localhost localhost.localdomain localhost4
localhost4.localhostdomain
::1         localhost localhost.localdomain localhost6
localhost6.localhostdomain
172.24.8.4  anaikregtestc73522602-cluster-com-mapr-vm0.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm0
172.24.8.5  anaikregtestc73522602-cluster-com-mapr-vm1.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm1
172.24.8.6  anaikregtestc73522602-cluster-com-mapr-vm2.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm2
172.24.8.7  anaikregtestc73522602-cluster-com-mapr-vm3.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm3
172.24.8.8  anaikregtestc73522602-cluster-com-mapr-vm4.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm4
```

2. Add a short alias for each node:

NOTE: You can use any short alias. In this example, vm0, vm1, vm2, vm3, and vm4 are used:

```
127.0.0.1    localhost localhost.localdomain localhost4
localhost4.localhostdomain
::1         localhost localhost.localdomain localhost6
localhost6.localhostdomain
172.24.8.4  anaikregtestc73522602-cluster-com-mapr-vm0.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm0 vm0
172.24.8.5  anaikregtestc73522602-cluster-com-mapr-vm1.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm1 vm1
172.24.8.6  anaikregtestc73522602-cluster-com-mapr-vm2.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm2 vm2
172.24.8.7  anaikregtestc73522602-cluster-com-mapr-vm3.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm3 vm3
172.24.8.8  anaikregtestc73522602-cluster-com-mapr-vm4.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm4 vm4
```

3. Perform step 1 and 2 for each node in the cluster.

Tez Upgrade Issues

- Preserving configuration on Ubuntu is not supported from EEP 4.1.1 and EEP 5.0.0 (1803) to EEP 6.0.0 (1808) or EEP 5.0.1 (1808).
- Preserving Tomcat configuration is not supported from any previous EEP to EEP 6.0.0 (1808).

- You must manually stop the Tomcat service and delete the Tomcat folder as a precondition if you are updating or upgrading Tez from the following EEPs:
 - EEP 4.0.0
 - EEP 4.1.0

User Names, Group Names, and LDAP

LDAP configuration allows you to use group names and usernames with spaces, so it is possible to name groups with spaces in them, for example, domain users. The following structure is possible in the MapR FileSystem:

```
drwxr-xr-x - afischer domain users 0 2018-10-03 16:10 /
user/abc
drwxr-xr-x - mapr mapr 0 2018-10-05 16:51 /
user/def
drwxr-xr-x - dschexnayder domain users 8 2018-10-10 13:30 /
user/xyz
drwxr-xr-x - mapr mapr 1 2018-10-09 14:23 /user/
hive
drwxr-xr-x - mapr mapr 11 2018-10-10 01:56 /user/
mapr
drwxr-xr-x - mlitovsky domain users 0 2018-10-06 11:08 /user/
hjbs
drwxr-xr-x - pcurtis domain users 5 2018-10-04 19:33 /user/
jknd
drwxr-xr-x - mapr mapr 3 2018-10-08 16:29 /user/
ewkd
drwxr-xr-x - talvarez domain users 0 2018-10-04 17:02 /
user/lkd
```

According to [HADOOP-12505](#), the Hadoop community does not allow spaces in group names, and because of that so does Hive. Each time you perform a query in Hive on a group name that has a space, you will see the following exception:

```
-chgrp: 'domain users' does not match expected pattern for group
```

The workaround is to not use spaces in group names or user names.

HiveServer 2 takes time to start because of get_all_databases

Materialized view registry and cache is introduced in [HIVE-14496](#) for Hive 2.3.0.

The goal of the cache is to avoid parsing and creating logical plans for the materialized views at query runtime. When a query arrives, you need to consult this cache and extract the logical plans for the views (which are already parsed) from it. Materialized view registry class scans all databases and tables in each database during initialization and that may cause long time to start HiveServer2.

Property `hive.materializedview.enable.views.registry` is added to control the usage of materialized view registry:

Property: `hive.materializedview.enable.views.registry`

Default value: true

Description: In case of a large amount of databases and tables in Hive, usage of materialized view registry and cache force HiveServer2 to scan all of them in order to cache the query plan for a view. This leads to an extremely long time for HiveServer2 to start.

This property is used to disable view registry and cache for this case. To disable materialized view registry and cache, add the following to `hive-site.xml` and restart Hive services.

```
<property>
  <name>hive.materializedview.enable.views.registry</name>
  <value>>false</value>
</property>
```

Database and Table Names Containing a Dot (.)

HIVE-16907 rejects queries with database and table names that contain a dot (.), and this behavior is backported to Hive 2.3.

Databases and tables that contain a dot (.) in the name are not supported now. For example:

```
{code}
insert into `tdb.t1` select * from t2;
{code}
Throws error:
{code}
FAILED: SemanticException
org.apache.hadoop.hive.ql.parse.SemanticException: Line 1:12 Table or
database name may not contain dot(.) character 'tdb.t1'
{code}
```

Avoid using unsupported characters in database and table names.

Hive Logging

This section describes Hive logging for Hive 2.1 and later releases and includes information about log splitting.

Hive Logging (Hive 2.3 and Later)

For Hive 2.3 and later starting with EEP 6.3.0, this topic describes the folder structure of the Hive logs and includes details about the log-file contents and how log files are installed in multinode installations.

Hive Log Folder Structure

Table 1 shows the Hive log folder structure:

Table

Folder or File			Description
<code>\${HIVE_HOME}/log</code>			Root folder for all Hive logs
	<code>hive-\${ADMIN_USER}-hiveserver2-\${HOSTNAME}.out</code> <code>hive-\${ADMIN_USER}-metastore-\${HOSTNAME}.out</code> <code>init_derby_db_\${TIMESTAMP}.log</code>		Each service has a separate file for logging
<code>\${HIVE_HOME}/log/\${ADMIN_USER}</code>			Root folder for admin cluster logs
		<code>\${ADMIN_USER}-hiveserver2-\${HOSTNAME}.log</code> <code>\${ADMIN_USER}-metastore-\${HOSTNAME}.log</code> <code>\${ADMIN_USER}-cli-\${HOSTNAME}.log</code>	Cluster admin log files

Table (Continued)

Folder or File				Description
<code>\${HIVE_HOME}/log/\${ADMIN_USER}/webhcat/</code>				Root folder for webHcat logs
			<code>webhcat.log</code> <code>webhcat-console.log</code> <code>webhcat-console-error.log</code>	WebHcat log files
<code>\${HIVE_HOME}/log/\${OTHER_USER}</code>				Root folder for a user other than the admin user
		<code>\${OTHER_USER}-cli-\${HOSTNAME}.log</code>		CLI log for a user other than the admin user

In Table 1:

This element	Represents
<code>\${HIVE_HOME}</code>	The Hive home folder, which is usually <code>/opt/mapr/hive/hive</code> .
<code>\${ADMIN_USER}</code>	The admin user of a cluster that runs HiveServer2 and HiveMetastore daemons. Usually, this is the <code>mapr</code> user.
<code>\${HOSTNAME}</code>	The name of the host where the daemon runs.
<code>\${TIMESTAMP}</code>	The date and time of log creation.
<code>\${OTHER_USER}</code>	A user other than the admin user.
<code>\${OTHER_USER}-cli-\${HOSTNAME}.log</code>	The log file that is created when <code>\${OTHER_USER}</code> launches the Hive CLI.

Content of Log Files

Table 2 shows the content of the log files:

Table

File Name	Description
<code>hive-\${ADMIN_USER}-hiveserver2-\${HOSTNAME}.out</code>	Contains information about when the HiveServer2 daemon was started and the PID of the file.
<code>hive-\${ADMIN_USER}-metastore-\${HOSTNAME}.out</code>	Contains information about when the HiveMetastore daemon was started and the PID of the file.
<code>\${ADMIN_USER}-hiveserver2-\${HOSTNAME}.log</code>	Contains information from the HiveServer2 daemons. This file also contains the job progress.
<code>\${ADMIN_USER}-metastore-\${HOSTNAME}.log</code>	Contains information from the HiveMetastore daemons.
<code>\${ADMIN_USER}-cli-\${HOSTNAME}.log</code>	Created when a user runs the Hive CLI over the <code>\${ADMIN_USER}</code> . This file contains the job progress.
<code>\${OTHER_USER}-cli-\${HOSTNAME}.log</code>	Created when a user runs the Hive CLI over the <code>\${OTHER_USER}</code> . This file also contains the job progress.
<code>init_derby_db_\${TIMESTAMP}.log</code>	Created if and only if Hive was configured for Apache Derby through cluster installation.

Log Files in a Multinode Hive Installation

Table 3 shows a Hive multinode installation (that is, Hive packages installed on different nodes):

Table

	Hive Metastore	HiveServer2	HiveWebHCat
node1	ε		
node2		ε	
node3			ε

See Table 4 for the log configurations:

Table

File or Folder Name	node1	node2	node3
hive-\${ADMIN_USER}-metastore- \${HOSTNAME}.out	ε		
\${ADMIN_USER}-metastore- \${HOSTNAME}.log	ε		
hive-\${ADMIN_USER}-hiveserver2- \${HOSTNAME}.out		ε	
\${ADMIN_USER}-hiveserver2- \${HOSTNAME}.log		ε	
/webhcat/			ε
webhcat.log			ε
webhcat-console.log			ε
webhcat-console-error.log			ε
/\${ADMIN_USER}/	ε	ε	ε

Related concepts

[Disabling Log Splitting of Hive Log Files](#) on page 5152

By default, Hive log files are split into HiveServer2 and Metastore log files, but you can disable log splitting by editing the `hive-env.sh` file.

[Splitting Hive Logs into HiveServer2 and Metastore logs by Process ID](#) on page 5152

Starting from the 1904 release, you can split Hive log files into HiveServer2 and Metastore log files by process ID.

Hive Logging (Hive 2.1 and Later)

For certain Hive 2.1 and later releases, this topic describes the folder structure of the Hive logs and includes details about the log-file contents and how log files are installed in multinode installations.

The Hive log information in this topic applies to Hive 2.1 and later releases beginning with the 1803 release-date identifier. Included are the Hive releases in Ecosystem Packs (EEPs) 3.0.3, 3.0.4, 3.0.5, 4.1.1, 4.1.2, 4.1.3, 4.1.4, 5.0.x, 6.0.x, 6.1.1, and 6.2.0. For more information about release-date identifiers, see [Release History for Ecosystem Packs](#) on page 7748.

Default log folder structure

Hive logs have the following folder structure:

```

${HIVE_HOME}/log
${HIVE_HOME}/log/hive-${ADMIN_USER}-hiveserver2-${HOSTNAME}.out
${HIVE_HOME}/log/hive-${ADMIN_USER}-metastore-${HOSTNAME}.out
${HIVE_HOME}/log/init_derby_db_${TIMESTAMP}.log
${HIVE_HOME}/log/${ADMIN_USER}

```

```

${HIVE_HOME}/log/${ADMIN_USER}/${ADMIN_USER}-hiveserver2-${HOSTNAME}.log
${HIVE_HOME}/log/${ADMIN_USER}/${ADMIN_USER}-metastore-${HOSTNAME}.log
${HIVE_HOME}/log/${ADMIN_USER}/webhcat/
${HIVE_HOME}/log/${ADMIN_USER}/webhcat/webhcat.log
${HIVE_HOME}/log/${ADMIN_USER}/webhcat/webhcat-console.log
${HIVE_HOME}/log/${ADMIN_USER}/webhcat/webhcat-console-error.log
${HIVE_HOME}/log/${OTHER_USER}
${HIVE_HOME}/log/${OTHER_USER}/${OTHER_USER}-hiveserver2-${HOSTNAME}.log

```

Here:

```

${HIVE_HOME} - Hive home folder. Usually this is /opt/mapr/hive/hive.
${ADMIN_USER} - Admin user of cluster that runs HiveServer2 and
HiveMetastore daemons. Usually this is mapr.
${HOSTNAME} - Name of the host where a daemon runs.
${TIMESTAMP} - Date and time of log creation.
${OTHER_USER} - Not an admin user.

```

Content of log files

Files `$HIVE_HOME/log/hive-${ADMIN_USER}-hiveserver2-${HOSTNAME}.out` and `$HIVE_HOME/log/hive-${ADMIN_USER}-metastore-${HOSTNAME}.out` contain information about when HiveServer2 and HiveMetastore daemons are started, and what are their PIDs.

Files `$HIVE_HOME/log/${ADMIN_USER}/${ADMIN_USER}-hiveserver2-${HOSTNAME}.log` and `$HIVE_HOME/log/${ADMIN_USER}/${ADMIN_USER}-hiveserver2-${HOSTNAME}.log` contain information from HiveServer2 and HiveMetastore daemons. File `${ADMIN_USER}-hiveserver2-${HOSTNAME}.log` also contains job progress.

The `${HIVE_HOME}/log/${OTHER_USER}/${OTHER_USER}-hiveserver2-${HOSTNAME}.log` file is created when somebody runs Hive CLI over the `${OTHER_USER}`. The `${OTHER_USER}-hiveserver2-${HOSTNAME}.log` file contains job progress.

The `${HIVE_HOME}/log/init_derby_db-${TIMESTAMP}.log` file is created if and only if Hive was configured for Derby Db through cluster installation.

Log files on multi node Hive installation

Consider Hive multi node installation (that is Hive packages are installed on different nodes). See Table 1:

Table

	Hive Metastore	HiveServer2	HiveWebHCat
node1	ε		
node2		ε	
node3			ε

See Table 2 for log configurations.

Table

	node1	node2	node3
<code>\${HIVE_HOME}/logs/hive-\${ADMIN_USER}-metastore-\${HOSTNAME}.out</code>	ε		
<code>\${HIVE_HOME}/logs/\${ADMIN_USER}/\${ADMIN_USER}-metastore-\${HOSTNAME}.log</code>	ε		
<code>\${HIVE_HOME}/logs/hive-\${ADMIN_USER}-hiveserver2-\${HOSTNAME}.out</code>		ε	

Table (Continued)

	node1	node2	node3
<code>\${HIVE_HOME}/logs/\${ADMIN_USER}/\${ADMIN_USER}-hiveserver2-\${HOSTNAME}.log</code>		ε	
<code>\${HIVE_HOME}/logs/\${ADMIN_USER}/webhcat/</code>			ε
<code>\${HIVE_HOME}/logs/\${ADMIN_USER}/webhcat/webhcat.log</code>			ε
<code>\${HIVE_HOME}/logs/\${ADMIN_USER}/webhcat/webhcat-console.log</code>			ε
<code>\${HIVE_HOME}/logs/\${ADMIN_USER}/webhcat/webhcat-console-error.log</code>			ε
<code>\${HIVE_HOME}/logs/\${ADMIN_USER}</code>	ε	ε	ε

Related concepts

[Disabling Log Splitting of Hive Log Files](#) on page 5152

By default, Hive log files are split into HiveServer2 and Metastore log files, but you can disable log splitting by editing the `hive-env.sh` file.

[Splitting Hive Logs into HiveServer2 and Metastore logs by Process ID](#) on page 5152

Starting from the 1904 release, you can split Hive log files into HiveServer2 and Metastore log files by process ID.

Disabling Log Splitting of Hive Log Files

By default, Hive log files are split into HiveServer2 and Metastore log files, but you can disable log splitting by editing the `hive-env.sh` file.

This information is valid for Hive-2.1+ starting from the EEP-1803 release.

Disabling Log Splitting of Hive Log Files

You can disable splitting the Hive log files into HiveServer2 and Metastore log files. To write all logs to the `hive.log` file, use these steps:

1. Edit the `hive-env.sh` file to set `SPLIT_HIVE_LOGS_INTO_FILES` property to `false`.

```
export SPLIT_HIVE_LOGS_INTO_FILES="false"
```

NOTE: To restore the default behavior from your previous Hive log configuration, set the `SPLIT_HIVE_LOGS_INTO_FILES` property to `true`, or comment out this property and restart Hive services.

2. Restart Hive services.

Splitting Hive Logs into HiveServer2 and Metastore logs by Process ID

Starting from the 1904 release, you can split Hive log files into HiveServer2 and Metastore log files by process ID.

To enable this feature, you must create a `hive-log4j2.properties` file, if one does not already exist, and then edit it:

1. If the `hive-log4j2.properties` file does not exist, create it from the template:

```
cp /opt/mapr/hive/hive-<version>/conf/
hive-log4j2.properties.template /opt/mapr/hive/hive-<version>/conf/
hive-log4j2.properties
```

2. Edit the `hive-log4j2.properties` file to replace Daily Rolling File Appender (DRFA) with the PID appender:

```
#property.hive.root.logger = DRFA
property.hive.root.logger = PID
#appenders = console, DRFA
appenders = console, PID
```

3. Restart Hive services.

The resultant Hive log structure is as follows:

The HiveServer2 log is located at:

```
${HIVE_HOME}/log/<ADMIN_USER>/
<ADMIN_USER>-hiveserver2-<HOSTNAME>.log.<PID>@<HOSTNAME>
```

Where:

- `${HIVE_HOME}` is the home folder for Hive.
- `<ADMIN_USER>` is the administrator user of the cluster. Typically, `mapr`.
- `<HOSTNAME>` is the host where HiveServer2 log file is placed.
- `<PID>` is the process ID of HiveServer2.

The Metastore log is located at:

```
${HIVE_HOME}/log/<ADMIN_USER>/
<ADMIN_USER>-metastore-<HOSTNAME>.log.<PID>@<HOSTNAME>
```

Where:

- `${HIVE_HOME}` is the home folder for Hive.
- `<ADMIN_USER>` is the administrator user of the cluster. Typically, `mapr`.
- `<HOSTNAME>` is the host where Hive Metastore log file is placed.
- `<PID>` is the process ID of Hive Metastore.

Logging CLI session

After splitting logs for HiveServer2 and Hive Metastore, CLI log appears separately for each CLI session at `${HIVE_HOME}/logs/<USERNAME>`.

A log file is created for every launched CLI session:

```
${HIVE_HOME}/log/<USERNAME>/
<USERNAME>-hiveserver2-<HOSTNAME>.log.<PID>@<HOSTNAME>
```

Where `<PID>` is process identifier of the CLI session.

Viewing Hive Audit Logs

Starting in EEP 7.1.0, you can view Hive audit logs for connected, disconnected, and total connected users.

To view audit logs, add the following property in the `hive-site.xml` file:

```
<property>
  <name>hive.enable.full.list.of.connected.users</name>
  <value>true</value>
</property>
```

By default, logs are updated every five seconds.

The following table describes the Hive Parameters used to manage the user audit logs:

Parameter	Default value	Description
hive.enable.full.list.of.connected.users	false	Enables the logging of the users currently connected to Hive when set to true. Use for debugging purposes only.
hive.full.list.of.connected.users.update.interval	5	Enables the log updates for currently connected Hive users in seconds. Must be used with the <code>hive.enable.full.list.of.connected.users</code> parameter. Use for debugging purposes only.

How to View Audit Logs

Enable the `hive.enable.full.list.of.connected.users` property in `hive-site.xml` file. You can view audit logs for connected, disconnected, and total connected users in HiveServer2 logs located in `${HIVE_HOME}/logs/mapr/mapr-hiveserver2-<hostname>.log` directory.

The following examples show you how the audit logs look in different scenarios:

Logs display for new user connection

Log entries for connected users provide the current session ID, username, IP address of the user, and the authentication type.

```
INFO [HiveServer2-Handler-Pool:
Thread-51] HiveSessionImpl.audit:
Connected:
sessionId=4c25b6d6-6e8e-4d56-83ba-52ea
271d0545 user=mapr ip=192.168.33.11
auth=MAPRSASL
```

Logs display for disconnected user

Log entries for disconnected users provide the current session ID, username, IP address of the user, and the authentication type.

```
INFO [HiveServer2-Handler-Pool:
Thread-51] HiveSessionImpl.audit:
Disconnected:
sessionId=4c25b6d6-6e8e-4d56-83ba-52ea
271d0545 user=mapr ip=192.168.33.11
auth=MAPRSASL
```

Logs display for total connected users

Log entries for total connected users start with a message `-Start of connected users list`, and provides the current session ID, username, IP address of the user, operation count, active time, idle time,

authentication type, and end with a message- End of the connected user's list.

```
INFO [pool-4-thread-1]
SessionManager.audit: Start of the
connected users list

INFO [pool-4-thread-1]
SessionManager.audit:
sessionId=c6261d49-1a71-4404-8cad-9cac
11a28151 user=mapr ip=192.168.33.11
operationCount=0 activeTime(s)=268
IdleTime(s)=268, auth=MAPRSASL

INFO [pool-4-thread-1]
SessionManager.audit:
sessionId=36b4d8d4-f201-43da-90eb-cb68
3d343b80 user=mapr ip=192.168.33.11
operationCount=0 activeTime(s)=198
IdleTime(s)=197, auth=MAPRSASL

INFO [pool-4-thread-1]
SessionManager.audit:
sessionId=32b50c8a-28ca-46a5-bbcd-963c
9b22af7f user=mapruser1
ip=192.168.33.11 operationCount=0
activeTime(s)=4 IdleTime(s)=4,
auth=PAM

INFO [pool-4-thread-1]
SessionManager.audit: End of the
connected user's list
```

How to Audit a Hive Query

The audit log in HiveServer2 allows you to trace the activities of a Hive query. The log entries for a Hive query includes username, user's IP address, query ID, query type, and query string.

To audit a Hive query, run any Hive query and then see the HiveServer2 logs located in \${HIVE_HOME}/logs/mapr/mapr-hiveserver2-<hostname>.log directory.

```
INFO [HiveServer2-Background-Pool: Thread-54]
Driver.audit: user=mapr ip=192.168.33.11
queryId=mapr_20210426155754_ace67f82-9a0c-4d0e-9ac5-c529b9798ec7 query
type=SHOWTABLES queryStr=show tables
```

HttpFS

HttpFS provides a service that enables you to submit HTTP REST calls to distributed file systems. You can use HttpFS to perform read and write operations on the file system.

Beginning with release 7.1.0, HttpFS is a part of mapr-hadoop. For HttpFS to work correctly, you must install the following Hadoop packages:

- mapr-hadoop-util
- mapr-hadoop-client
- mapr-hadoop-core

For more information about the Hadoop packages, see [Installing Hadoop and YARN](#) on page 295.

This section includes the following topics:

Authentication on Secure Clusters for HttpFS

In secure clusters, HttpFS can use any of the following authentication methods:

- HttpFS authentication, such as native security (MapR-SASL)
- Kerberos (for which additional configuration is required)
- Plain security using PAM, which is determined automatically

In a secure cluster, HttpFS runs a script to set the following properties by default. In a non-secure cluster, you must add the following properties manually to the `httpfs-site.xml` file:

```
httpfs.hadoop.authentication.type=multiauth
httpfs.authentication.type=multiauth
```

Configuring HttpFS

You can configure the following features to perform distributed file system operations securely through HttpFS.

The following topics describe how to configure various security mechanisms for HttpFS.

Kerberos Authentication for HttpFS

Complete the following steps to enable Kerberos security on nodes that run the HttpFS service:

Modify the `httpfs-site.xml` File

About this task

A Kerberos-ready version of the `httpfs-site.xml` file called `httpfs-site.xml.kerberos` is provided in `/opt/mapr/hadoop/hadoop-3.3.x/etc/hadoop/httpfs-site.xml`. Edit this file and specify the Kerberos principal name for the nodes running HttpFS, restart the HttpFS server, and then test the set-up. Each step is explained here.

To set up the `httpfs-site.xml` file for each node running the HttpFS service, follow these steps:

Procedure

1. Assign a new name to the existing `httpfs-site.xml` file (to preserve the original version when the file gets overwritten in step 2):

```
cd /opt/mapr/hadoop/hadoop-3.3.x/etc/hadoop
cp httpfs-site.xml httpfs-site.xml.original
```

2. Edit the `httpfs-site.xml` file, and insert the principal name as shown, substituting your fully qualified domain name and realm for `<node_name>@<REALM>`:

```
<property>
<name>httpfs.authentication.type</name>
<value>kerberos</value>
</property>

<property>
<name>httpfs.hadoop.authentication.type</name>
<value>kerberos</value>
</property>

<property>
<name>httpfs.authentication.kerberos.principal</name>
<value>HTTP/<node_name>@<REALM></value>
</property>

<property>
<name>httpfs.authentication.kerberos.keytab</name>
<value>/opt/mapr/conf/mapr.keytab</value>
</property>

<property>
<name>httpfs.hadoop.authentication.kerberos.principal</name>
<value>mapr/<node_name>@<REALM></value>
</property>

<property>
<name>httpfs.hadoop.authentication.kerberos.keytab</name>
<value>/opt/mapr/conf/mapr.keytab</value>
</property>

<property>
<name>httpfs.authentication.kerberos.name.rules</name>
<value>DEFAULT</value>
</property>
```

3. Restart the HttpFS server so the changes will take effect:

```
maprcli node services -name httpfs -action restart -nodes <node_name>
```

4. Test that security is in place by entering the following command to create a file in the file system. The command will fail if security is not set up correctly:

```
curl --negotiate -u : -b ~/cookiejar.txt -c ~/cookiejar.txt -i -X PUT
"http://<node_name>:14000/webhdfs/v1/user/mapr/some_file?op=MKDIRS"
```

PAM Authentication for HttpFS

About this task

Complete the following steps to enable PAM authentication for HttpFS.

Procedure

1. Add the `httpfs.hadoop.authentication.type` and `httpfs.authentication.type` properties to the `/opt/mapr/hadoop/hadoop-3.3.4/etc/hadoop/httpfs-site.xml` file, as shown:

```
<property>
  <name>httpfs.hadoop.authentication.type</name>
  <value>multiauth</value>
</property>

<property>
  <name>httpfs.authentication.type</name>
  <value>multiauth</value>
</property>
```

NOTE: On secure clusters, the **multiauth** authentication is enabled by default.

2. Restart the HttpFS service:

```
maprcli node services -name httpfs -action restart -nodes <space
delimited list of nodes>
```

3. After restarting the service, run cURL with the PUT operation, as shown in this example:

NOTE: If HttpFS is configured with plain authentication through PAM, the cURL request must contain a username and password.

```
curl -X PUT "https://mapr:mapr@<node_name>:14000/webhdfs/v1/tmp/example?
op=mkdirs"
```

SSL Security for HttpFS

About this task

On a secure cluster, HttpFS uses the secure-by-default configuration. Use the following topics to explicitly enable custom security on HttpFS.

You also need to enable SSL if [custom security](#) is enabled.

Verifying SSL Security for HttpFS

You need to run `curl` commands to verify that HTTPS is enabled for HttpFS.

Procedure

Run one of the following `curl` commands to check that HTTPS is enabled. These commands fetch the file **some_file.txt** from the file system under `/user/mapr` and attempt to open it securely over HTTPS.

- To check if HTTPS is enabled, run the following command

```
curl -u <user_name> -k
"https://<node_name>:14000/webhdfs/v1/user/mapr/some_file.txt?op=open"
```

- If you configured Hue to use SSL encryption with certificate-based authentication for communication with HttpFS, run the following command

- ```
curl -u <user_name> -k
--cert /opt/mapr/hue/hue-<version>/cert.pem
--key /opt/mapr/hue/hue-<version>/hue_private_keystore.pem
"https://<node_name>:14000/webhdfs/v1/user/mapr/some_file.txt?op=open"
```

### Enabling SSL Security for HttpFS

You can enable SSL security for HttpFS using an `ssl_keystore` and `ssl_truststore`. These are generated automatically for a secure cluster in `/opt/mapr/conf/`. When using SSL on nonsecure clusters, you must manually generate a keystore and truststore.

### About this task

To enable SSL security for HttpFS with credential provider, use the following steps:

### Procedure

1. Enable SSL in `etc/hadoop/httpfs-site.xml` configuration file:

```
<property>
 <name>httpfs.ssl.enabled</name>
 <value>true</value>
 <description>
 Whether SSL is enabled. Default is false, i.e. disabled.
 </description>
</property>
```

2. Use the credential provider to create secure SSL passwords:

```
hadoop credential create ssl.server.keystore.password -value 123 \
-provider localjceks://file/home/mapr/httpfs.jceks
```

```
hadoop credential create ssl.server.keystore.keypassword -value 123 \
-provider localjceks://file/home/mapr/httpfs_keypassword.jceks
```

3. Run the Java `keytool` command to create an SSL certificate for the HttpFS server:

```
keytool -genkey -alias jetty -keyalg RSA
```

You will be prompted to answer a series of questions to create a keystore file named `.keystore`.

- You must enter the same password for “keystore password” as the value of the property `ssl.server.keystore.password` set while creating secure SSL passwords.
- You must answer “What is your first and last name?” (i.e. “CN”) with the host name of the machine where the HttpFS Server will be running.

The `.keystore` file will be stored in the HttpFS user home directory.

4. Configure the `etc/hadoop/ssl-server.xml` file to set the SSL keystore location:

```
<property>
 <name>ssl.server.keystore.location</name>
 <value>/home/mapr/.keystore</value>
 <description>Keystore to be used. Must be specified.
</description>
</property>
```

- Configure the `/opt/mapr/hadoop/hadoop-3.3.4/etc/hadoop/https-site.xml` file with the following property to set credential provider path and enable the credential provider:

```
<property>
 <name>hadoop.security.credential.provider.path</name>
 <value>localjceks://file/home/lmccay/aws.jceks</value>
 <description>Path to interrogate for protected credentials.</description>
</property>
```

- Restart the HttpFS server:

```
maprcli node services -action restart -name https -nodes <node>
```

### User Impersonation for HttpFS

If you want HttpFS to impersonate a user from a set of hosts, or to impersonate a user that belongs to a set of groups, you can configure the proxy-user functionality. Configuring this functionality enables the proxy user to perform “doAs” operations. To configure proxy-user functionality, add configuration properties to the `https-site.xml` and `core-site.xml` files.

Complete the following steps to configure user impersonation for HttpFS:

- Add the following configuration properties to the `https-site.xml` file:
  - `https.proxyuser.#USER#.hosts`
  - `https.proxyuser.#USER#.groups`
- Replace `#USER#` with the user name of the proxy that can perform “doAs” operations. For the host property, you can add a list of host names as the value. For the group property, you can add a list of groups as the value. Alternatively, you can add a wildcard character (\*) as the value for host and group properties. To add multiple users, copy the property and replace `#USER#` with the proxy user name.

Host Example

```
<property>
 <name>https.proxyuser.mapr.hosts</name>
 <value>*</value>
</property>
```

Group Example

```
<property>
 <name>https.proxyuser.mapr.groups</name>
 <value>*</value>
</property>
```

To use impersonation, issue a cURL command with the `doas=<impersonated_user's name>` parameter.

#### Example 1

Where `user.name` is `mapr` and `doas` (or the impersonated user's name) is **sampleusername**.

```
curl -i -X PUT -T one
"http://<node_name>:14000/webhdfs/v1/user/mapr/TEST/one
?op=CREATE&user.name=mapr&doas=sampleusername&data=true"
-H "Content-Type:application/octet-stream"
```

#### Example 2

For any user (and password) other than the mapr user (for example, **test\_user1**), set the `hadoop.proxyuser.<user_name>.hosts</name>` property in the `/opt/mapr/hadoop/hadoop-3.3.x/etc/hadoop/httpfs-site.xml` file, as shown.

```
<property>
 <name>hadoop.proxyuser.<test_user1>.hosts</name>
 <value>*</value>
</property>
```

Run cURL.

Where `trueuser.name` is **test\_user1** and `doas` (or the impersonated user's name) is **test\_user2**.

```
curl -u fred -i -X PUT -T /etc/hosts --header "Content-Type:application/
octet-stream"
"http://<node_name>:14000/webhdfs/v1/<path_to_test_file>
?op=CREATE&doas=<test_user2>&data=true&user.name=<test_user1>"
```

### Network Timeout for HttpFS

The network timeout is the amount of idle time (in milliseconds) that can pass before the HttpFS network connection closes automatically. Depending on your installed EEP, you can use one of the following properties to control the network timeout:

EEP*	Timeout Property	Default Timeout (ms)	Config File
9.0.0 and later	<code>hadoop.http.idle_timeout.ms</code>	60000	<code>/opt/mapr/hadoop/hadoop-&lt;version&gt;/etc/hadoop/httpfs-site.xml</code>
7.0.0 through 8.1.0	<code>hadoop.http.max_idle_time.ms</code>	10000	<code>/opt/mapr/httpfs/httpfs-&lt;version&gt;/etc/hadoop/httpfs-site.xml</code>

\*For a guide to the supported EEPs, see [Ecosystem Pack Support and Lifecycle Status](#) on page 7664.

If your applications require the network connection to remain open longer than the default timeout, consider increasing the timeout value. To change the timeout value:

1. Add a timeout property to the `httpfs-site.xml` file. For the appropriate property and the location of the `httpfs-site.xml` file, see the nearby table.

For example, in a cluster installed with EEP 7.0.0, adding the following property to `/opt/mapr/httpfs/httpfs-<version>/etc/hadoop/httpfs-site.xml` sets a timeout value of 30 seconds:

```
<property>
 <name>hadoop.http.max_idle_time.ms</name>
 <value>30000</value>
</property>
```

2. Restart the HttpFS server so the changes take effect:

```
maprcli node services -name httpfs -action restart -nodes <node_name>
```

### Finishing HttpFS Configuration Changes

After making configuration changes for the `mapr-httpfs` package, run the `configure.sh` script on all nodes where the `mapr-httpfs` package was installed:

```
sudo bash /opt/mapr/server/configure.sh -R
```

### Creating a Test File in HttpFS

Following is an example of test file using CURL in via HttpFS.

#### Example

```
$: curl \
> -k \
> -i \
> -u mapr:mapr \
> -X PUT \
> -T /etc/passwd \
> -H 'Content-Type: application/octet-stream' \
> 'https://node7.cluster.com:14000/webhdfs/v1/tmp/testfile?
op=CREATE&data=true'
HTTP/1.1 100 Continue

```

### Troubleshooting HttpFS

#### About this task

To debug authentication issues, follow these steps:

#### Procedure

1. Edit the `log4j` properties file located at `/opt/mapr/hadoop/hadoop-3.3.x/etc/hadoop/` `httpfs-log4j.properties` and insert the following lines to activate debug capabilities:

```
log4j.logger.org.apache.hadoop.fs.http.server=DEBUG, httpfs
log4j.logger.org.apache.hadoop.lib=DEBUG, httpfs
log4j.logger.org.apache.hadoop.security.authentication.server=DEBUG,
httpfs
```

2. Search the logs located at `/opt/mapr/hadoop/hadoop-3.3.x/logs` for the words *ERROR* or *Exception*.

## Hue

Hue is the open source UI that interacts with Apache Hadoop and its ecosystem components, such as Hive, Pig, and Oozie. It is also a framework for creating interactive Web applications.

For information about Hue versions, see the [Ecosystem Support Matrix](#).

Hue is supported on the following browsers:

Windows	Linux	Mac
Chrome	Chrome	Chrome
Firefox 3.6+	Firefox 3.6+	Firefox 3.6+
Safari 5+		Safari 5+
Internet Explorer 8+		

### Hue Feature Support

The following table lists supported and unsupported Hue functionality:

Supported	Not Supported
<p>Query editors</p> <ul style="list-style-type: none"> <li>Hive (for performing queries on Apache Hive)</li> <li>Impala (for submitting interactive SQL and HiveQL queries)</li> <li>DB Query (for viewing data in MySQL, PostgreSQL, Oracle and Sqlite)</li> <li>Pig (for submitting Pig scripts)</li> <li>Job Designer (for creating and submitting MapReduce/Streaming/Java jobs)</li> <li>Spark (beta feature for submitting Spark jobs for hue-3.9.0/3.10.0)</li> <li>Drill (for performing queries on Apache Drill through JDBC) in hue-3.12</li> </ul> <p>Data browsers</p> <ul style="list-style-type: none"> <li>Metastore Tables (for managing databases, tables, and partitions of the Hive metastore)</li> <li>HBase browser (for creating, editing, and searching tables)</li> <li>Sqoop Transfer (for transferring bulk data between Hadoop and various types of structured datastores)</li> </ul> <p>Workflows</p> <ul style="list-style-type: none"> <li>Oozie (for creating and running workflow and coordinator jobs)</li> </ul> <p>Hue 4.X supports ADLS browser for accessing files and directories in Azure Data Lake Store.</p> <p>S3 Browser (for accessing files and directories in Amazon S3)</p> <p>File Browser (for accessing files and directories in file system)</p> <ul style="list-style-type: none"> <li>Job Browser (for accessing MapReduce applications)</li> <li>User Admin (for adding, deleting, and managing Hue users and groups)</li> </ul>	<p>Hue integration with the following components is not supported:</p> <ul style="list-style-type: none"> <li>Sentry 1.6, 1.7 on a secure cluster that uses Data Fabric-SASL authentication.</li> </ul> <p> <b>NOTE:</b> Sentry 1.6, 1.7 on a secure cluster that uses Kerberos authentication is supported.</p> <ul style="list-style-type: none"> <li>Solr Search</li> <li>Zookeeper</li> </ul>

### Configure Hue

After you install Hue, perform the following configuration steps:

1. Complete the general configuration steps. This includes integrating Hue with ResourceManager and HttpFS.
2. Perform the steps to integrate each additional component that you want to use with Hue.
  - Hive
  - HPE Data Fabric Database
  - Impala

- Oozie
- Spark

You may also want to:

- Configure Security
- Configure DB Query
- Configure Hue Interface Authentication

**NOTE:** The `hue.ini` file is the main configuration file for running Hue on a cluster. This file is located at `/opt/mapr/hue/hue-<version>/desktop/conf/hue.ini`. When you update the value of a property in the `hue.ini`, remove any hashes (`##`) that appear directly before the property name. You must also restart Hue for these changes to take effect.

### Configure General Hue Settings

The following topics provide instructions for configuring general Hue settings:

*Enable User Impersonation for Hue*

#### About this task

To enable Hue to submit requests on behalf of any other user, complete the following steps:

#### Procedure

1. Verify or configure the following lines to the `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/core-site.xml` file for all nodes running ResourceManager:

```
<property>
 <name>hadoop.proxyuser.<default_user>.hosts</name>
 <value>*</value>
</property>

<property>
 <name>hadoop.proxyuser.<default_user>.groups</name>
 <value>*</value>
</property>
```

2. To enable the Hue file browser to view files in the filesystem, add the following proxy user settings in the configuration block of the `https-site.xml`:

```
<!-- Hue HttpFS proxy user setting -->
<configuration>
 <property>
 <name>https.proxyuser.<default_user>.hosts</name>
 <value>*</value>
 </property>

 <property>
 <name>https.proxyuser.<default_user>.groups</name>
 <value>*</value>
 </property>
</configuration>
```

3. Perform any additional Hue configurations and then restart Hue so that the changes will take effect. See [Starting the Hue Webserver](#).

In most cases, `mapr` is the `<default_user>`. The `<default_user>` you specify must also be the `default_user` that is configured in the `[desktop]` section of the `hue.ini`.

**NOTE:** Based on the ecosystem components that you want to use, additional configuration may be required.

#### *Disable an Application in the Hue Interface (optional)*

##### **About this task**

If you want to disable an application (such as Impala), follow these steps:

##### **Procedure**

1. In the `[desktop]` section of the `hue.ini` file, uncomment the `# app_blacklist=` statement and insert the name of the app you want to disable (`impala` in this example).

**NOTE:** Do not remove `search` from the `app_blacklist`. The Hue UI will not work if the search application is enabled.

```
Comma-separated list of apps not to load at server startup.
Note that rdbms is the name used for dbquery.
app_blacklist=spark,zookeeper,search,impala,sqoop,rdbms
```

**NOTE:** After removing an application from `app_blacklist`, you must update the Hue internal database to create the tables required for the application that was enabled:

```
sudo /opt/mapr/server/configure.sh -R
```

2. Once all changes are made, restart Hue so the changes will take effect.

**NOTE:** You can re-enable a blacklisted application at any time, and then restart Hue.

```
maprcli node services -name hue -action restart -nodes <ip_address>
```

#### *Change the File Size Restriction for the File Browser (optional)*

##### **About this task**

The Hue File Browser will not open files that are 1.0 GB or greater. Starting with Hue 4.2, file size limitation equals 1.0 GB with no way to modify it.

##### *Prevent Hue from Creating User Home Directories*

Describes how to disable the automatic creation of user home directories.

By default, Hue creates a directory in the filesystem for a user when the user logs in to the Hue service.

For example, if a `/user` volume is configured in the filesystem, Hue creates a `/user/<username>` directory in the volume each time a user logs in to the Hue service. If a quota is not placed on that `/user` volume, a user could potentially place an unlimited amount of data in the volume.

If you do not want Hue to create a home directory for each user that logs in to the Hue service, disable the `ensure_home_directory` option in the `[desktop]` `[[auth]]` section of the `hue.ini` file, as shown:

```
[desktop]
 [[auth]]
 ensure_home_directory=false
```

Restart the Hue service for the setting to take effect.

**NOTE:** This functionality is available by default starting in EEP 7.1.0. Previous versions of EEP can obtain this functionality through a patch. See [Applying a Patch](#) on page 431.

### Configure Hue Interface Authentication

You can configure the following user authentication methods for the Hue interface:

Authentication Method	Description
Hue User Administration	Use the Hue interface to create and manage user accounts for each Hue user.
LDAP	Import LDAP users into Hue and then use LDAP to authenticate users with their LDAP credentials. For more information, see <a href="#">Configure Hue with LDAP</a> .
PAM	Use multiple PAM modules to authenticate users. PAM authentication is configured by default. When you use this method, you cannot edit users in the Hue interface.

#### *Using a Non-Default Authentication Method*

#### About this task

The default authentication method is PAM.

To edit the authentication method used for the Hue interface, complete the following steps:

#### Procedure

1. Set the backend property equal to your selected authentication method. For example, to use Hue's user authentication, select `desktop.auth.backend.AllowFirstUserDjangoBackend`.
2. If you choose not to use PAM, comment the `pam_service` property.

#### Example

Example hue.ini configured to use PAM Authentication

```
[[auth]]
Authentication backend. Common settings are:
- django.contrib.auth.backends.ModelBackend (entirely Django backend)
- desktop.auth.backend.AllowAllBackend (allows everyone)
- desktop.auth.backend.AllowFirstUserDjangoBackend
(Default. Relies on Django and user manager, after the first login)
- desktop.auth.backend.LdapBackend
- desktop.auth.backend.PamBackend - WARNING: existing users in Hue may be
unaccessible if they not exist in OS
- desktop.auth.backend.SpnegoDjangoBackend
- desktop.auth.backend.RemoteUserDjangoBackend
- libsaml.backend.SAML2Backend
- libopenid.backend.OpenIDBackend
- liboauth.backend.OAuthBackend
(Support Twitter, Facebook, Google+ and LinkedIn
backend=desktop.auth.backend.PamBackend

The service to use when querying PAM.
pam_service=sudo sshd login
```

### Configure Hue with LDAP

If you use LDAP to authenticate users, you can retrieve user account information from your LDAP database and import it directly into Hue's User Admin directory. This way, you do not have to use the Hue interface to create user accounts for each Hue user individually.

Once you import users, you can also use LDAP with Hue to authenticate users with their LDAP credentials. Each of these tasks is explained in the following sections:

#### Setting up Users from an LDAP Database

##### About this task

This diagram shows how the LDAP client embedded in Hue searches the LDAP server's database for user names, and then adds them to the User Admin directory for Hue.

The following table shows the parameters you need to set in the `ldap` section of the `hue.ini` file so you can import users.

**WARNING:** The `hue.ini` file is located at `/opt/mapr/hue/hue-<version>/desktop/conf/`.

Parameter	Description	Comments
<code>ldap_url</code>	The URL of your LDAP server.	
<code>base_dn</code>	Top of the search tree, which defines the search scope.	
<code>bind_dn</code>	Distinguished name (DN) of the user to bind as.	Can be omitted for anonymous searches.
<code>bind_password</code>	Password of the bind user.	Can be omitted for anonymous searches.
<code>user_filter</code>	Limits the scope of the search by applying a filter.	This parameter is optional.
<code>user_name_attr</code>	The attribute used for username in the LDAP schema.	Examples: <code>cn</code> (for common name) or <code>uid</code> (for user ID).

To set up Hue users by importing information from an LDAP database:

## Procedure

1. Establish communication with the LDAP server by setting the `ldap_url` parameter in the `ldap` section of the `hue.ini` file. Uncomment the line and change the value from the default ( `ldap://localhost` ) to the URL for your LDAP server.

```
URL of the LDAP server
ldap_url=ldap://localhost
```

2. Provide the `base_dn` information to define the search scope. Uncomment the line where `base_dn` is defined and replace with your `base_dn`.

```
The search base for finding users and groups
base_dn="DC=mycompany,DC=com"
```

3. If your LDAP server does not support anonymous searches, you need to provide the `bind_dn` and `bind_password`. Uncomment the lines with these parameters and change the values to your `bind_dn` and your `bind_password`.

```
Distinguished name of the user to bind as -- not necessary if the LDAP
server
supports anonymous searches
bind_dn="CN=ServiceAccount,DC=mycompany,DC=com"

Password of the bind user -- not necessary if the LDAP server
supports
anonymous searches
bind_password=
```

4. If you want to narrow the scope of the directory search, specify a `user_filter` in the `users` section under the `ldap` section of the `hue.ini` file. This is optional.

```
[[[users]]]

Base filter for searching for users
user_filter="objectclass=*"
```

5. Set the `user_name_attr` parameter in the `users` section under the `ldap` section of the `hue.ini` file. If your LDAP directory schema does *not* use the attribute `sAMAccountName` for the username, uncomment the line and change the value of the `user_name_attr` to the attribute you use. For example, if the directory schema uses the `uid` attribute, change the value of the parameter as shown:

```
[[[users]]]

The username attribute in the LDAP schema
user_name_attr=sAMAccountName
```

```
user_name_attr=uid
```

6. Restart `https` so `ldap` settings will take effect.
7. Restart Hue once all configuration changes have been made so the changes will take effect.

## Authenticating Hue Users with LDAP Credentials

This section explains how to edit the `ldap` section of the `hue.ini` file to enable Hue user authentication with LDAP credentials. These instructions assume you have completed the steps in [Setting up Users from an LDAP Database](#).

**WARNING:**

If you switch to authentication through LDAP credentials, the Hue User Admin users will lose superuser privileges unless you take one of the following actions:

- Import one or more superuser accounts from LDAP and assign them superuser permission.
- If you have already enabled the LDAP authentication back end, log into Hue using the LDAP back end, which will create an LDAP user. Next, disable the LDAP authentication back end and use User Admin to give the superuser permission to the new LDAP user.

Before you edit the parameters in the `hue.ini` file, determine whether your LDAP server allows anonymous searches.

- If anonymous searches *are* allowed, use the **direct bind** method.
- If anonymous searches *are not* allowed, use bind credentials (also known as **search and bind**).

The following flow chart shows which parameters you must specify for each of these authentication methods:

These are the parameters you need to set in the `ldap` section of the `hue.ini` file so you can authenticate Hue users with LDAP credentials:

Parameter	Description	Comments
search_bind_authentication	Determines which authentication method to use: search and bind, or direct bind.	<p>When set to <i>true</i>, Hue performs an LDAP search using <code>bind_dn</code> and <code>bind_password</code> as provided in <code>hue.ini</code>. The search can be further limited by the search filter <code>user_filter</code>.</p> <p>When set to <i>false</i>, Hue performs a direct bind to LDAP using the credentials provided from one of these sources:</p> <ul style="list-style-type: none"> <li>the UPN, formed by concatenating <code>&lt;shortname&gt;</code> (the user name provided on the Hue login page) and <code>nt_domain</code> (if <code>nt_domain</code> is specified)</li> <li>the <code>ldap_username_pattern</code> (if <code>nt_domain</code> is not specified)</li> </ul>
nt_domain	The NT domain to connect to. This parameter is <i>only</i> used with Active Directory.	<p>Used with the <i>direct bind</i> method of authentication.</p> <p>If <code>nt_domain</code> is specified, then <code>ldap_username_pattern</code> is ignored.</p>
ldap_username_pattern	Used to connect to directory services other than Active Directory.	<p>Used with the <i>direct bind</i> method of authentication.</p> <p>Usually takes the form <code>"cn=&lt;username&gt;,dc=example,dc=com"</code></p>
backend	The backend to use for authenticating users.	Needs to be set to <code>desktop.auth.backend.LdapBackend</code> for Hue authentication.

### Using Bind Credentials (Search and Bind)

#### About this task

To use the search and bind method for LDAP authentication, edit these parameters in the `ldap` section of the `hue.ini` file:

#### Procedure

1. Set `search_bind_authentication=true`.
2. In the `Authentication backend` section, add the following line after the `##backend=` statement: Hue searches `base_dn` for an entry with `user_name_attr` that contains the user name provided on the Hue login page.

```
backend=desktop.auth.backend.LdapBackend
```

3. Restart Hue once all configuration changes have been made so the changes will take effect.

### Using Direct Bind

**About this task**

To use the direct bind method for LDAP authentication, edit these parameters in the `ldap` section of the `hue.ini` file:

**Procedure**

1. Set `search_bind_authentication=false`.
2. If you are using the Active Directory directory service, uncomment the line with the `nt_domain` parameter. Change the value from `nt_domain=mycompany.com` to the NT domain you want to connect to.
3. If you are using any other directory service, uncomment the line with `ldap_username_pattern` and specify the format, such as the one shown here: Note that `<username>` will be replaced by the information provided on the Hue login page.

```
ldap_username_pattern="cn=<username>,dc=example,dc=com"
```

4. Restart Hue once all configuration changes have been made so the changes will take effect.

**Configure the Hue Database**

The Hue server stores user-account information, the job submission history, and Hive queries in one of the following supported databases:

- SQLite, the embedded Hue database (the default database)
- MySQL
- PostgreSQL
- Oracle
- MariaDB

**NOTE:** Using SQLite is not recommend.

*Configure Hue to Store Data in MySQL or MariaDB*

**About this task****Procedure**

1. To configure Hue to store data in MySQL, create a new database in MySQL and grant privileges to a Hue user to manage this database.

```
mysql> create database hue;
Query OK, 1 row affected (0.01 sec)
mysql> grant all on hue.* to 'hue'@'localhost' identified by
'secretpassword';
Query OK, 0 rows affected (0.00 sec)
```

2. Configure the database connection parameters in the `[desktop][[database]]` section of `hue.ini`. Set the following properties with your database connection parameters:

```
[desktop]
[[database]]
engine=mysql
host=<host>
port=3306
user=<user>
password='<password>'
name=<database>
```

Example of configuration:

```
[desktop]
[[database]]
engine=mysql
host=node1
port=3306
user=hue
password=hue_password
name=hue
```

If the connection is secured through SSL/TLS, specify the CA, Cert, and Key paths, as shown in the following example:

```
[desktop]
[[database]]
[[options]]
options='{ "ssl": { "key": "/path/to/client-key.pem", "cert": "/path/to/client-cert.pem", "ca": "/path/to/ca.pem" } }'
```

You can find detailed documentation for other options in the Django [Connecting to the Database](#) documentation.

3. Perform the initial data migration:

```
sudo /opt/mapr/server/configure.sh -R
```

4. Restart Hue:

```
maprcli node services -name hue -action restart -nodes <node_with_hue>
```

*Configure Hue to Store Data in PostgreSQL*

### About this task

**Procedure**

1. Install the following packages:

<b>CentOS</b>	<code>yum install gcc python-devel postgresql-devel</code>
<b>SLES</b>	<code>zypper install gcc python-devel postgresql-devel</code>
<b>Ubuntu</b>	<code>apt-get install gcc python-dev postgresql-server-dev-all</code>

2. Ensure that the `pg_config` command is in your PATH. For example, on CentOS with PostgreSQL 9.4 development package from the [postgresql.org](https://www.postgresql.org) official repository, you need to add the directory with `pg_config` manually:

```
export PATH="/usr/pgsql-9.4/bin:$PATH"
```

3. Install the Python `psycopg2` package in Hue:

```
cd /opt/mapr/hue/hue-<version>
source ./bin/activate
pip install psycopg2
deactivate
```

4. Configure database connection parameters in the `[desktop][[database]]` section of `hue.ini`. Set the following properties for your database connection parameters:

```
[desktop]
[[[database]]
engine=postgresql_psycopg2
host=<host>
port=5432
user=<user>
password=<password>
name=<database>
schema=<schema>
```

**Example of Configuration**

```
[desktop]
[[[database]]
engine=postgresql_psycopg2
host=node1
port=5432
user=hue
password=hue_password
name=hue
schema=public
```

5. Perform the initial data migration:

```
sudo /opt/mapr/server/configure.sh -R
```

## 6. Restart Hue:

```
maprcli node services -name hue -action restart -nodes <node_with_hue>
```

### Configure Hue to Store Data in Oracle Database

#### About this task

**NOTE:** To configure Hue with Oracle 12, you need the [Oracle 11 Instant Client](#) Base and SDK.

#### Procedure

1. Install the following packages:

<b>RedHat</b>	<code>yum install gcc libnsl</code>
<b>SLES</b>	<code>zypper install gcc</code>
<b>Ubuntu</b>	<code>apt-get install gcc</code>

2. Ensure that the library required to install the Oracle module in Hue is available through the `LD_LIBRARY_PATH` environment variable. The module that provides support for Oracle in Hue requires the `libcintsh.so` library to be available through the `LD_LIBRARY_PATH` environment variable. Typically, the library is located under the `$ORACLE_HOME` or `$ORACLE_HOME/lib` directories. Also, the library might include a version in the filename (for example, `libcintsh.so.11.1`), but the Oracle module for Hue requires it to be named `libcintsh.so`.

- a) Ensure that the `ORACLE_HOME` environment variable is set:

```
ORACLE_HOME="<path_to_oracle_installation>"
```

- b) Use the `find` command to locate the library:

```
find "$ORACLE_HOME" -name "libcintsh.so*"
```

- c) Go to the directory and ensure that the library is available and has the proper filename. If not, you can create a symbolic link:

```
ln -s libcintsh.so.11.* libcintsh.so
```

- d) Add the following variables to the Hue environment configuration by creating a file in `/opt/mapr/hue/hue-<version>/desktop/conf/env.d/`. For example, create `/opt/mapr/hue/hue-<version>/desktop/conf/env.d/99-custom.sh` with the following content:

```
export ORACLE_HOME="<path_to_oracle_installation>"
export LD_LIBRARY_PATH="$ORACLE_HOME:$LD_LIBRARY_PATH"
```

or the following, depending on your Oracle configuration:

```
export ORACLE_HOME="<path_to_oracle_installation>"
export LD_LIBRARY_PATH="$ORACLE_HOME/lib:$LD_LIBRARY_PATH"
```

### 3. Install the Python cx\_Oracle package in Hue:

```
cd /opt/mapr/hue/hue-<version>
. bin/activate
pip install cx_Oracle==5.3
deactivate
```

**NOTE:** Python cx\_Oracle version 5.3 is supported.

### 4. Configure the database connection parameters in the [desktop][database] section of hue.ini. Note these considerations:

- Make sure that you have the appropriate permissions to use LOBs; for example, SQL GRANT on SYS.DBMS\_LOB.
- SID refers to the Oracle system ID, which is used to uniquely identify the database.

```
[desktop]
...
[[database]]
engine=oracle
host=<host>
port=1521
user=<user>
password=<password>
name=<SID of the database>
```

- To achieve a multithreading environment, you can specify the options={'threaded': true} parameter in this section. For example:

```
[desktop]
...
[[database]]
engine=oracle
host=node1
port=1521
user=hue
password=hue_password
name=XE
options={'threaded': true}
```

By setting the port=0 parameter, you can use the Oracle Service Name instead of specifying the SSID. For example:

```
[desktop]
...
[[database]]
engine=oracle
port=0
user=hue
password=hue_password
name=node1:1521/hue
```

### 5. Invoke configure.sh to perform the initial data migration:

```
sudo /opt/mapr/server/configure.sh -R
```

## 6. Restart Hue:

```
maprcli node services -action restart -nodes <node_with_hue> -name hue
```

### Configure Hue with Security

Based on the Hue version and the version of the other components that Hue communicates with, you can configure the following security features:

**NOTE:** You cannot enable both Kerberos and MapR-SASL on the same cluster.

#### *Configure Hue to use Kerberos*

After you set up a Kerberos principal and keytab file, you can configure Hue to use the Kerberos authentication protocol.

After you set up a Kerberos principal and keytab file, enable the Kerberos Ticket Renewal service, update `hue.ini` and `core-site.xml` with the required parameters, and restart the Warden and Hue services.

### Enabling the Kerberos Ticket Renewer Service

The Kerberos Ticket Renewer service (`kt_renewer`) renews tickets for the Hue service. Hue automatically starts the `kt_renewer` process on clusters that use Kerberos for authentication. Kerberos tickets have a default expiration time of 7 days. The `kt_renewer` service extracts the Kerberos ticket from the keytab file and renews the ticket before it expires.

You can access the `kt_renewer` process log files in the following locations:

- `${HUE_HOME}/logs/kt_renewer.out`
- `${HUE_HOME}/logs/kt_renewer.log`

To use the Kerberos Ticket Renewer service:

1. Enable the Kerberos Ticket Renewer Service:
  - In the `kdc.conf` file, add the `max_renewable_life` parameter.
  - In the `krb5.conf` file, add the `renew_lifetime` parameter.
2. Update the `hue.ini` file to include the Kerberos credentials cache path (`ccache_path`) and ticket renewal frequency (`keytab_reinit_frequency`), as shown in the following example:

```
[desktop]
[[kerberos]]
...
Path to keep Kerberos credentials cached
ccache_path=/tmp/custom_hue_krb5_ccache
Frequency in seconds with which Hue will renew its
keytab
keytab_reinit_frequency=86400
...
```

### Modifying the hue.ini File

In the `kerberos` section of the `hue.ini` file, make the following changes:

1. Supply the path to Hue's Kerberos keytab file.
2. Supply the Kerberos principal name for Hue.
3. Supply the path to kinit.

4. In the `[[yarn_clusters]] [[default]]` section:
  - If you are using a certificate signed by the CA (Certificate Authority), set the `ssl_cert_ca_verify` value to `True`.
  - If you are using a self-signed certificate or no certificate, leave the value set to `False`.
5. **For Hue with secure Hive:** In the `beeswax` section, make sure that the `hive_conf_dir` property points to a directory containing a valid `hive-site.xml` file (either the original or a synced copy).
6. **Optional:** To enable SSL encryption, see [Enable SSL Encryption Between Hue and Hive](#).
7. Make sure that you specified a fully-qualified domain name (FQDN) for all services integrated with Hue that uses Kerberos:

**HttpFS:** Set the `webhdfs_url` property in the `[hadoop] [[hdfs_clusters]] [[default]]` section.

**HiveServer2:** Set the `hive_server_host` property in the `[beeswax]` section.

**Impala:** Set the `server_host` property in the `[impala]` section.

**Spark:** Set the `livy_server_url` property in the `[impala]` section.

**NOTE:** Support for Kerberos integration with Livy was introduced in Hue 4.X.

**HBase:** Set the `hbase_clusters` property in the `[hbase]` section.

**Drill:** Refer to section.

The changes are summarized in the following `hue.ini` files, which you can use as a template:

```
[desktop]
[[kerberos]]
Path to Hue's Kerberos keytab file
hue_keytab=/opt/mapr/conf/mapr.keytab

Kerberos principal name for Hue
hue_principal=mapr/<hostname>@<realm>
Substitute your hostname and realm in the example below
hue_principal=mapr/perfnode181.perf.lab@dev-maprtech

Path to keep Kerberos credentials cached
ccache_path=/tmp/custom_hue_krb5_ccache
Frequency in seconds with which Hue will renew its keytab
keytab_reinit_frequency=86400

Path to kinit
Note that the actual path depends on which Linux OS you are using
kinit_path=/usr/bin/kinit

[beeswax]
If Kerberos security is enabled, use fully-qualified domain name
(FQDN)
hive_server_host=<FQDN of Hive Server>
Hive configuration directory, where hive-site.xml is located.
hive_conf_dir=/opt/mapr/hive/hive-<version>/conf
Change this if your Hive is secured
security_enabled=true
Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
mechanism=GSSAPI

[impala]
```

```

Host of the Impala Server (one of the Impalad)
server_host=<FQDN of Impalad>
Kerberos principal
impala_principal=mapr/perfnode181.perf.lab@dev-maprtech

[hadoop]
...
[[hdfs_clusters]]
[[[default]]]
Enter the filesystem uri
fs_defaultfs=maprfs:///

Use WebHdfs/HttpFs as the communication mechanism.
Domain should be the NameNode or HttpFs host.
Default port is 14000 for HttpFs.
webhdfs_url=https://<FQDN of HttpFS>:14000/webhdfs/v1

Change this if your HDFS cluster is secured
security_enabled=True

Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
mechanism=GSSAPI
...
[[[yarn_clusters]]]
[[[default]]]
Enter the host on which you are running the ResourceManager
resourcemanager_host=localhost

The port where the ResourceManager IPC listens on
resourcemanager_port=8032

Whether to submit jobs to this cluster
submit_to=true

Change this if your YARN cluster is secured
security_enabled=true

URL of the ResourceManager API
resourcemanager_api_url=https://localhost:8090

URL of the ProxyServer API
proxy_api_url=https://localhost:8090

URL of the HistoryServer API
history_server_api_url=https://localhost:19890

Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
mechanism=GSSAPI

In secure mode (HTTPS), if SSL certificates from Resource Manager's
Rest Server have to be verified against certificate authority
ssl_cert_ca_verify=False

[spark]
The Livy Server URL.
livy_server_url=https://<FQDN of Livy Server>:8998

Whether Livy requires client to perform Kerberos authentication.
security_enabled=True

Security mechanism of authentication none/GSSAPI/MAPR-SECURITY.
mechanism=GSSAPI

[liboozie]

```

```
The URL where the Oozie service runs on. This is required in order for
users to submit jobs.
oozie_url=https://<FQDN of Oozie>:<oozie_port_number>/oozie

Requires FQDN in oozie_url if enabled
security_enabled=true
Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
mechanism=GSSAPI

[hbase]
Comma-separated list of HBase Thrift servers for clusters in the format
of '(name|host:port)'.
Use full hostname with security.
If using Kerberos we assume GSSAPI SASL, not PLAIN.
hbase_clusters=(Cluster|<FQDN of Hbase Thrift Server>:9090)
Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
mechanism=GSSAPI
```

**NOTE:** You need to manually set `security_enabled` property to `true` and `mechanism` property to `GSSAPI` for a Kerberised environment. These options are automatically configured only on a `mapr-SASL` cluster.

### Modifying the `core-site.xml` File

In the `core-site.xml` file, provide the shortname for the Kerberos principal as shown. In addition, verify that you configured the proxyuser during configuration. See [Configure Hue](#) for details.

```
<!-- Hue security configuration -->
<property>
 <name>hue.kerberos.principal.shortname</name>
 <value>mapr</value>
</property>
<property>
 <name>hadoop.proxyuser.mapr.groups</name>
 <value>*</value> <!-- A group that all users of Hue belong to, or the
wildcard value "*" -->
</property>
<property>
 <name>hadoop.proxyuser.mapr.hosts</name>
 <value><hue_server_FQDN></value>
</property>
```

### Restarting Warden and Hue

After you make all the changes to the files listed above, restart Warden and Hue so the changes will take effect.

#### *Configure Hue to use MapR-SASL*

You can configure Hue to use MapR-SASL for its communications with various components on a secure cluster. Hue automatically detects and sets the security configuration of the cluster and its components. Therefore, in some cases, minimal configuration is required.

The following components are supported by Hue with MapR-SASL:

- HttpFS
- YARN and Spark History Server
- Hive
- Livy

- HBase Thrift
- Oozie
- Drill

**NOTE:** For secure by default clusters or for clusters where the customSecurity flag is not added, Hue automatically sets security\_enabled to true and mechanism to MAPR-SECURITY for these components. In all other cases, \${security\_enabled} and \${mechanisms} variables are set to false and none respectively, but these options can be configured manually for custom setups.

An example of a default configuration with automatically defined security\_enabled and mechanism properties for HttpFS is as follows:

```
[hadoop]
[[hdfs_clusters]]
HA support by using HttpFs
[[[default]]]
...
Change this if your HDFS cluster is secured
security_enabled=${security_enabled}

Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
mechanism=${mechanism}
...
```

An example of a manual configuration of security\_enabled and mechanism properties for HttpFS is as follows:

```
[hadoop]
[[hdfs_clusters]]
HA support by using HttpFs
[[[default]]]
...
Change this if your HDFS cluster is secured
security_enabled=true

Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
mechanism=MAPR-SECURITY
...
```

**NOTE:** After you configure the hue.ini, you must restart Hue. However, if you configure multiple sections of the same file, you can restart Hue one time after your updates are complete.

#### *Configure LDAP Authentication Between Hue and Hive*

##### **About this task**

You can configure Hue to use LDAP Authentication when it communicates with HiveServer2. Before you configure Hue to use LDAP authentication with HiveServer2, verify that HiveServer2 is configured to use LDAP authentication. For more information, see [Configure HiveServer2 to use LDAP Authentication](#) on page 4971.

Complete the following steps to configure LDAP authentication between Hue and Hive:

##### **Procedure**

1. Configure Hue to connect to Hive with LDAP authentication:

- a) Configure the [beeswax] section of the hue.ini: set mechanism option.

```
[beeswax]
...
Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
mechanism=LDAP
```

- b) Configure the [beeswax] section of the hue.ini (for Hive integration only):

```
[beeswax]
...
Override the default desktop username and password of the hue user
used for authentications with other services.
e.g. Used for LDAP/PAM pass-through authentication.
auth_username=sampleuser
auth_password=123456
...
```

Or configure the [desktop] section of the hue.ini to set the username and password for all services that require username/password authentication:

```
[desktop]
...
Default LDAP/PAM/.. username and password of the hue user used
for authentications with other services.
Inactive if password is empty.
e.g. LDAP pass-through authentication for HiveServer2 or Impala.
Apps can override them individually.
auth_username=sampleuser
auth_password=123456
...
```

2. **Optional:** Configure Hue to authenticate users through LDAP. See [Configure Hue with LDAP](#).
3. Restart Hue:

```
maprcli node services -name hue -action restart -nodes <space delimited
list of nodes>
```

### *Configure PAM Authentication Between Hue and Hive*

#### **About this task**

In Hue 3.10, you can configure Hue to use PAM authentication when it communicates with HiveServer2. Before you configure Hue to use PAM authentication with HiveServer2, verify that HiveServer2 is configured to use PAM authentication. See [Configure HiveServer2 to Use PAM Authentication](#) for more information.

Complete the following steps to configure PAM authentication between Hue and Hive:

## Procedure

1. Configure the [beeswax] section of the hue.ini file. Set the mechanism option to none. Set the auth\_username and auth\_password options in the [desktop] or [beeswax] sections of hue.ini (where auth\_username and auth\_password are the user credentials for the user who authenticates the Hue service with HiveServer2).

The following example summarizes these changes:

```
[desktop]
...
Default LDAP/PAM/.. username and password of the Hue user used
for authentication with other services.
Inactive if password is empty.
e.g. LDAP pass-through authentication for HiveServer2 or Impala.
Apps can override them individually.
auth_username=mapr
auth_password=<user_password>
...
[beeswax]
...
Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
mechanism=none
```

2. Restart Hue:

```
maprcli node services -name hue -action restart -nodes <Hue node>
```

### Configure File Upload Restrictions in Hue

Allows administrators to control which file types users can upload through the **File Browser**.

### About this task

Starting with the DEP 10.1.0 release, Hue 4.11.0 allows administrators to control which file types users can upload through the File Browser.

Filtering is based strictly on the file name extension, not file content. The check uses the last suffix after the final dot (.) and is case-insensitive.

If both allow and restrict lists are defined, restrict takes precedence.

### Default Behavior (No Restrictions Configured)

By default, both parameters in hue.ini are commented out:

```
[filebrowser]
restrict_file_extensions=.exe, .zip, .rar, .tar, .gz
allow_file_extensions=.tsv, .csv, .xlsx
```

### Behavior in Default State

When both settings remain commented:

- All file extensions are allowed.
- No filtering is applied during upload.
- Files with any extension (including .exe, .zip, etc.) can be uploaded.
- Files without extensions are also allowed.

In this state, Hue performs no extension-based validation. This is the out-of-the-box behavior after installation unless explicitly configured otherwise.

### Configuration Location

Edit:

```
/opt/mapr/hue/hue-4.11.0/desktop/conf/hue.ini
```

Under:

```
[filebrowser]
```

### Configuration Options

#### Restrict Extensions

Blocks specific file types:

```
[filebrowser]
restrict_file_extensions=.exe, .zip, .rar, .tar, .gz
```

#### Allow Extensions

Permits only specified types:

```
[filebrowser]
allow_file_extensions=.csv, .tsv, .xlsx
```

### Combined Example

```
[filebrowser]
restrict_file_extensions=.exe, .zip, .rar, .tar, .gz
allow_file_extensions=.csv, .tsv, .xlsx
```

### Behavior:

- .exe, .zip, .rar, .tar, .gz - Blocked
- .csv, .tsv, .xlsx - Allowed
- Any other extension - Blocked
- Files without extension - Blocked

### Restart Requirement

After updating hue.ini, restart Hue:

```
maprcli node services -name hue -action restart -nodes <node>
```

Changes take effect only after a restart.

#### NOTE:

- Validation is extension-based only (no MIME/content inspection).
- The final extension determines behavior (archive.tar.gz & gz).
- Recommended for production: combine both restrict and allow lists for stricter control.

*Enable SSL Encryption Between Hue and Hive***About this task**

Hue automatically determines when SSL encryption is enabled in Hive by reading the `hive-site.xml` file.

**Procedure**

1. The following example shows how to correctly configure the directory path where the `hive-site.xml` file is located in the `hive_conf_dir` property in `[beeswax]` section of the `hue.ini` file:

```
[beeswax]
...
Hive configuration directory, where hive-site.xml is located
hive_conf_dir=/opt/mapr/hive/hive-2.3/conf
```

2. The following examples show how to enable or disable Hue verification of service certificates by configuring `ssl_cacerts` and `ssl_validate` properties in `[desktop]` section of the `hue.ini` file:

**Example for enabling certificate verification:**

```
[desktop]
...

Path to default Certificate Authority certificates. As example: /
path/to/cacert.pem
ssl_cacerts=/opt/mapr/conf/ssl_truststore.pem

Choose whether Hue should validate certificates received from the
server.
ssl_validate=true
```

**Example for disabling certificate verification:**

```
[desktop]
...

Path to default Certificate Authority certificates. As an example: /
path/to/cacert.pem
ssl_cacerts=

Choose whether Hue should validate certificates received from the
server.
ssl_validate=false
```

3. After you change these properties, restart Hue to apply your changes:

```
maprcli node services -name hue -action start -nodes <hostname>
```

*Enable SSL Encryption Between Hue and HttpFS***About this task**

As of HttpFS 1.0-1504 and Hue 3.7-1505, you can enable SSL encryption and mutual-based authentication between Hue and HttpFS on a secure cluster that is version 4.0.2 or greater.

Complete the following steps to enable SSL encryption and mutual-based authentication between Hue and HttpFS on a secure cluster:

**Procedure**

1. Configure HttpFS to use SSL or verify that HttpFS is configured to use SSL. For details, see [SSL Security for HttpFS](#).
2. Set the `webhdfs_url` property in the `[hadoop] [[hdfs_clusters]] [[[default]]]` section of the `hue.ini` file to contain the correct URL for HttpFS with the HTTPS schema and domain of the HttpFS server:

```
[hadoop]
[[hdfs_clusters]]
[[[default]]]
 # Use WebHdfs/HttpFs as the communication mechanism.
 # Domain should be the NameNode or HttpFs host.
 # Default port is 14000 for HttpFs.
 webhdfs_url=https://node1.cluster.com:14000/webhdfs/v1
```

3. You can enable or disable Hue verification of service certificates by configuring `ssl_cacerts` and `ssl_validate` properties in the `[desktop]` section of the `hue.ini` file.

**Example for enabling certificate verification:**

```
[desktop]
...

Path to default Certificate Authority certificates. As example: /
path/to/cacert.pem
ssl_cacerts=/opt/mapr/conf/ssl_truststore.pem

Choose whether Hue should validate certificates received from the
server.
ssl_validate=true
```

**Example for disabling certificate verification:**

```
[desktop]
...

Path to default Certificate Authority certificates. As example: /
path/to/cacert.pem
ssl_cacerts=

Choose whether Hue should validate certificates received from the
server.
ssl_validate=false
```

4. [OPTIONAL] Configure mutual authentication between Hue and HttpFS. Add the following configuration in the `hue.ini` file under the `[hadoop] [[hdfs_clusters]] [[[default]]]` section.

- `mutual_ssl_auth=True`
- `ssl_cert=/path/to/certificate.pem`
- `ssl_key=/path/to/private_key.pem`

Use absolute paths for `ssl_cert` and `ssl_key`. Hue does not support private keys with a passphrase in this step.

The changes are summarized in the following example in the `hue.ini` file, which you can use as a template:

```
[hadoop]
[[hdfs_clusters]]
HA support by using HttpFs
[[[default]]]
Use WebHdfs/HttpFs as the communication mechanism.
Domain should be the NameNode or HttpFs host.
Default port is 14000 for HttpFs.
webhdfs_url=https://node1.cluster.com:14000/webhdfs/v1
...
SSL certificate based authentication
ssl_cert=/path/to/certificate.pem
ssl_key=/path/to/private_key.pem
```

##### 5. Restart Hue.

```
maprcli node services -name hue -action start -nodes <ip_address>
```

##### 6. To test that SSL encryption is enabled for HttpFS, run the following command:

```
curl -k --cert /path/to/certificate.pem --key /path/to/private_key.pem
"https://node1.cluster.com:14000/webhdfs/v1?
op=GETFILESTATUS&user.name=mapr"
```

#### *Troubleshoot Hue Security Issues*

To troubleshoot Kerberos security issues, enable the debugger by changing the following setting in the `/opt/mapr/conf/env.sh` file:

```
uncomment the following line to debug client kerberos issues
#MAPR_KERBEROS_DEBUG="-Dsun.security.krb5.debug=true -Dsun.security.spnego.d
ebug=true -Djavax.net.debug=all"
```

Under the Hue installation directory, check `logs/runcpserver.log` for errors. Some sample error messages are shown below.

#### **Could not start SASL**

If you see this message, try using [renewable tickets](#):

```
TypeError: TTransportException('Could not start SASL: Error in
sasl_client_start (-1) SASL(-1): generic failure: GSSAPI Error: Unspecified
GSS failure. Minor code may provide more information (Ticket expired)',)
is not JSON serializable
```

Run the `kinit` command to generate a new ticket with a long running lifetime, then restart the Hue webserver.

## Configuration Error

If you see this message, it means that the ticket generated by the `kinit` command from `mapr login kerberos` was not copied to `/tmp/hue_krb5_ccache`:

```
Caused by: javax.security.auth.login.LoginException: Configuration Error - useTicketCache should be set to true to use the ticket cache /tmp/hue_krb5_ccache
```

This can happen when you generate a new ticket after the original ticket expires and forget to copy it into the ticket cache. Run the following command to copy the ticket into the ticket cache:

```
kinit -k -t /opt/mapr/conf/mapr.keytab -c /tmp/hue_krb5_ccache mapr/perfnode181.perf.lab@dev-maprtech
```

## Password incorrect while getting initial credentials

This message (Password incorrect while getting initial credentials) appears when you create a keytab file, but try to authenticate with a password. The act of creating a keytab causes a new random key to be placed in the Kerberos database and into the keytab file (`/opt/mapr/conf/mapr.keytab`). That key does not have a password associated with it, so you can only authenticate using the keytab.

If you want to authenticate with a password, run the `cpw` command in `kadmin` instead of the `ktadd` command.

## Integrate Hue

This section contains the following topics with information for integrating Hue with other ecosystem components:

### Integrate Hue with HPE Data Fabric Database Binary Tables

You can use the Hue HBase application to access HPE Data Fabric Database binary tables.

**NOTE:** In order to use the Hue HBase application, you need to install the HBase Client and the HBase Thrift Gateway. For more information, see the [Installing Manually](#) on page 152.

#### Step 1: Setting up HPE Data Fabric Database Binary Table Mapping

To use the Hue HBase application to access HPE Data Fabric Database binary tables, you need to set the `hbase.table.namespace.mappings` property.

### Table Mapping Naming Conventions

A table mapping takes the form `name:map`, where `name` is the table name to redirect and `map` is the modification made to the name. The value in `name` can be a literal string or contain the `*` wildcard. When mapping a name with a wild card, the mapping is treated as a directory. Requests to tables with names that match the wild card are sent to the directory in the mapping.

When mapping a name that is a literal string, you can choose from two different behaviors:

- End the mapping with a slash to indicate that this mapping is to a directory. For example, the mapping `mytable1:/user/aaa/` sends requests for table `mytable1` to the full path `/user/aaa/mytable1`.
- End the mapping without a slash, which creates an alias and treats the mapping as a full path. For example, the mapping `mytable1:/user/aaa` sends requests for table `mytable1` to the full path `/user/aaa`.

**Example: Map Table Names to HPE Data Fabric Database**

In the following example, the `hbase.table.namespace.mappings` property is set so that any flat table name, such as `mytable`, is treated as a HPE Data Fabric Database table in the directory `/tables_dir/mytable`.

```
<property>
 <name>hbase.table.namespace.mappings</name>
 <value>*:/tables_dir</value>
</property>
```

Once you finish enabling table mapping in the `core-site.xml` file, start (or restart) the HBase thrift server so the changes will take effect.

```
maprccli node services -name hbasethrift -action start -nodes node001
```

**Step 2: Configure Hue for HPE Data Fabric Database****About this task**

To configure Hue for HPE Data Fabric Database, edit the `hbase` section of the `hue.ini` file, which looks like this:

```
[hbase]
Comma-separated list of HBase Thrift servers for
clusters in the format of '(name|host:port)'.
hbase_clusters=(Cluster|localhost:9090)

Hard limit of rows or columns per row fetched before truncating.
truncate_limit = 500
```

In this file, make the following changes:

**Procedure**

1. Uncomment the `## hbase_clusters=(Cluster|localhost:9090)` statement and provide the list of HBase Thrift servers.

```
hbase_clusters=(<clustername1>|<hostname1>:9090),(<clustername2>|
<hostname2>:9090)[,...]
```

2. Uncomment the `truncate_limit` statement and change the value if necessary.

**Integrate Hue with Hive**

Describes how to integrate Hue with Hive through settings in the `hue.ini` file.

**About this task**

By default, Hue connects to a single instance of HiveServer2 through the `hive_server_host` parameter in `hue.ini`; however, if high availability (HA) is enabled for HiveServer2, Hue can leverage that. If one instance of HiveServer2 goes down, the client automatically connects to another instance of HiveServer2.

**Verify the Hive Version**

Before you integrate Hue with HiveServer2 (HA or single instance), verify that the path specified in the `hive_conf_dir` property applies to the Hive version that you have installed. If needed, update the path to reflect the Hive version that you have installed.

```
Hive configuration directory, where hive-site.xml is located
hive_conf_dir=/opt/mapr/hive/hive-<version>/conf
```

If Hue and Hive are installed on separate nodes, you must also copy the Hive conf directory to the Hue node.

### Integrating Hue with HiveServer2 High Availability

If you want Hue to leverage HiveServer2 HA, [enable high availability for HiveServer2](#), and update the `hue.ini` file to include the following properties and settings:

```
[beeswax]
#Whether to use service discovery for llap.
hive_discovery_llap = true
#Is llap (hive server interactive) running in HA.
hive_discovery_llap_ha = true
#Whether to use service discovery for HiveServer2.
hive_discovery_hs2 = true
[libzookeeper]
#ZooKeeper ensemble; comma-separated list of host/port.
ensemble=<host:port>:5181
```

Note that the `hive_server_host` and `hive_server_port` properties in `hue.ini` are not required if using HiveServer2 HA. Service discovery overrides the server and thrift port.

Perform any additional Hue configurations and then restart Hue for changes to take effect. See [Starting the Hue Webserver](#).

### Integrating Hue with a Single Instance of HiveServer2

Update the beeswax section of the `hue.ini` file to include the following properties and settings:

 **NOTE:** This is not required on a single node cluster.

```
[beeswax]
Host where HiveServer2 is running.
If Kerberos security is enabled, use fully-qualified domain name (FQDN).
hive_server_host=<FQDN of Hive Server>

Port that HiveServer2 Thrift server runs on.
hive_server_port=10000
```

Perform any additional Hue configurations and then restart Hue for changes to take effect. See [Starting the Hue Webserver](#).

### Configuring Data and Metadata Directories

When Hue and Hive are used together, they are usually configured to share metadata and data directories. However, you can create separate directories for Hue and Hive.

The locations of the shared directories are specified by the following properties in the `hive-site.xml` file:

- `hive.metastore.uris` (the hostname and port of the Hive Metastore node)

- `hive.metastore.warehouse.dir` (the directory where the default database for the warehouse is located)

See [Configure Shared Hive Data and Metadata Directories for Hue](#) and [Configure Separate Hive Data and Metadata Directories for Hue](#) for more information.

*Configure Shared Hive Data and Metadata Directories for Hue*

### About this task

To configure shared Hive data and metadata directories for Hue:

### Procedure

1. Change the `hive.metastore.uris` property as shown:

```
<property>
 <name>hive.metastore.uris</name>
 <value>thrift://localhost:9083</value>
 <description> URI where clients contact Hive metastore server </
description>
</property>
```

**NOTE:** The `hive.metastore.warehouse.dir` property can keep its default value and does not need to be changed.

2. Enable Hue impersonation by setting the following property to true.

```
<property>
 <name>hive.metastore.execute.setugi</name>
 <value>true</value>
 <description> Set this property to enable Hive Metastore service
impersonation in unsecure mode.
 In unsecure mode, setting this property to true causes the metastore
to execute DFS operations
 using the client's reported user and group permissions. Note that
this property must be set on
 BOTH the client and server sides. </description>
</property>
```

3. Set the location of the `sharelib`.

```
<property>
 <name>oozie.service.WorkflowAppService.system.libpath</name>
 <value>/oozie/share/lib</value>
</property>
```

4. To enable the Hive Metastore service to share the embedded Derby database, add the following property blocks to the `hive-site.xml` file on the node running `hiveserver2` to point to the location of the Derby metastore:

```
<property>
 <name>javax.jdo.option.ConnectionURL</name>
 <value>jdbc:derby:;databaseName=/<local dir>/metastore_db;create=true</value>
 <description>JDBC connect string for a JDBC metastore</description>
</property>

<property>
 <name>javax.jdo.option.ConnectionDriverName</name>
 <value>org.apache.derby.jdbc.EmbeddedDriver</value>
 <description>Driver class name for a JDBC metastore</description>
</property>
```

5. To enable the Hive Metastore service to share a MySQL database, add the following property blocks to the `hive-site.xml` file:

```
<property>
 <name>javax.jdo.option.ConnectionURL</name>
 <value>jdbc:mysql://<ip_address>:3306/hive_11?createDatabaseIfNotExist=true</value>
</property>

<property>
 <name>javax.jdo.option.ConnectionDriverName</name>
 <value>com.mysql.jdbc.Driver</value>
</property>

<property>
 <name>javax.jdo.option.ConnectionUserName</name>
 <value><UserName></value>
 <description>Substitute the actual username</description>
</property>

<property>
 <name>javax.jdo.option.ConnectionPassword</name>
 <value><Password></value>
 <description>Substitute the actual password</description>
</property>
```

### *Configure Separate Hive Data and Metadata Directories for Hue*

#### **About this task**

If you want to store Hue data and metadata in separate directories from Hive data and metadata, follow these steps:

#### **Procedure**

1. Copy `hive-site.xml` to a new location. (The original `hive-site.xml` file remains in the previous location for use by Hive.)
2. Edit `hue.ini` and change the `hive_conf_dir` property so it points to the new location for `hive-site.xml`.

3. Change the `hive.metastore.warehouse.dir` property in the new `hive-site.xml` file so it points to the directory where Hue data will be located.
4. Change the `hive.metastore.uris` property so it points to the directory for Hue's `metastore_db`.
5. Set the `hive.metastore.execute.setugi` property to `true`.

```
<property>
 <name>hive.metastore.execute.setugi</name>
 <value>true</value>
 <description> Set this property to enable Hive Metastore service
impersonation in non-secure mode.
 In non-secure mode, setting this property to true causes the
metastore to execute DFS operations
 using the client's reported user and group permissions. Note that
this property must be set on
 BOTH the client and server sides. </description>
</property>
```

## Integrate Hue with Spark (Experimental Only)

### About this task

You can configure Hue to use the Spark Notebook UI. This allows users to submit Spark jobs from Hue.

**NOTE:** Spark Notebook is a feature that utilizes the Spark REST Job Server (Livy). The `mapr-livy` package must be installed on a node where the `mapr-spark` package is installed or the Livy service will not start.

### Procedure

1. In the `[spark]` section of the `hue.ini`, set the `livy_server_host` parameter to the host where the Livy server is running.

```
[spark]
IP or hostname of livy server.
livy_server_url=https://<host>:8998
```

**NOTE:** If the Livy server runs on the same node as the Hue UI, you are not required to set this property as the value defaults to the local host.

2. Restart Hue.

```
maprccli node services -name hue -action restart -nodes <hue node>
```

### Results

#### Additional Information

- If needed, you can use the Control System or `maprccli` to start, stop, or restart the Livy Server. For more information, see [Managing Services](#) on page 1397.

**NOTE: Troubleshooting Tip**

If you have more than one version of Python installed, you may see the following error when executing Python samples:

```
Py4JJavaError: An error occurred while calling
z:org.apache.spark.api.python.PythonRDD.collectAndServe...
```

**Workaround:**

Set the following environment variables in `/opt/mapr/spark/spark-<version>/conf/spark-env.sh`:

```
export PYSARK_PYTHON=/usr/bin/python2.7
export PYSARK_DRIVER_PYTHON=/usr/bin/python2.7
```

**Integrate Hue with Drill**

Starting in EEP 6.0, Drill is officially supported with Hue. When you integrate Drill with Hue, users can run Drill queries from the Hue interface and visualize data.

Drill integrates with Hue through configuration options in the `/opt/mapr/hue/hue-<version>/conf/hue.ini` file. A user can authenticate to Hue through Plain, Kerberos, or Data Fabric-SASL authentication. The user that authenticates to Hue is the user that runs the Drill queries from Hue.

When connecting to Drill, Hue performs outbound impersonation to Drill as the user that authenticated to Hue. Drill accepts the outbound impersonation from Hue as an inbound impersonation. Drill then performs outbound impersonation to the filesystem or MapR Database.

**NOTE:** In a secure cluster, you can only access the Hue interface through HTTPS.

**NOTE:** SSL encryption is currently not supported.

**Prerequisites**

Note the following prerequisites before you integrate Hue with Drill:

- The cluster must have the latest versions of [Hue](#), [Drill](#), and [HTTPFS](#) installed. Hue uses HTTPFS to communicate with the file system. You can see the latest component versions in the [Component Versions for Released EEPs](#). If you install Hue and Drill on a secure cluster, Hue and Drill are installed with the default security configurations and outbound impersonation is enabled.
- **Installer**

When you install Hue and Drill using the Installer, HTTPFS is installed automatically, and Hue is automatically configured to integrate Drill without having to perform any manual configuration. The installer configures a Zookeeper connection to Drill in `hue.ini`, by default.
- **Manual Installation**
  - Install HTTPFS and then configure Hue, as described in the following section, *Configuring Hue*
- In a secure cluster, Drill must have [user impersonation enabled](#).

- Drill has an inbound impersonation policy option, `exec.impersonation.inbound_policies`, that allows the Hue process user (proxy user) to impersonate the Hue authenticated user as an outbound impersonation from Hue to Drill. This option is automatically configured when Drill and Hue are installed using the Installer with default security enabled, or when you run `configure.sh` on a secure cluster. If you do not run `configure.sh`, you must manually add this option to the impersonation configuration in the `/opt/mapr/drill/drill-<version>/conf/drill-override.conf` file, as shown:

```
impersonation.enabled: true,
impersonation.max_chained_user_hops: 3,
exec.impersonation.inbound_policies: "[{proxy_principals:{users:
[\"mapr\"]},target_principals:{users:[\"*\"]}}]",
```

- If you plan to use Kerberos for authentication, you will need to include the Hue keytab file and Kerberos principal name for Hue in the `hue.ini` file. If needed, complete the steps listed in the [Creating a Kerberos Principal and Extracting the Kerberos Ticket from the keytab File](#) sections on the [Configure Hue to use Kerberos](#) on page 5177 page.

## Configuring Hue

If you manually installed Hue, Drill, and HTTPFS, you must modify the `hue.ini` file to include the configuration information needed for Hue to connect with Drill and HTTPFS. The `hue.ini` file contains sections where you configure Hue to integrate with various components, like Drill and HTTPFS. You can access the `hue.ini` file in the `/opt/mapr/hue/hue-<version>/desktop/conf` directory. Start/Restart the services after you update the `hue.ini` file.

**NOTE:** If you installed Hue and Drill using the Installer, these options are populated automatically in the `hue.ini` file; no configuration is required. In a secure cluster, the authentication mechanism defaults to MAPR-SECURITY.

Complete the following steps to integrate Hue with Drill:

### 1. Edit the Drill configuration in `hue.ini`.

The `hue.ini` file contains a `[[[drill]]]` section under which you can see configuration options needed for Hue to connect with Drill. You must uncomment an option (remove the `#` character) in the `hue.ini` file for the option to take effect.

The following tables list and describe the Drill options with possible values and also provide examples:

Options	Descriptions	Examples
<code>connection_type=</code>	<p>Tells Hue how to connect to Drill. Enter one of the following values:</p> <ul style="list-style-type: none"> <li><code>direct</code></li> <li><code>zookeeper</code></li> </ul> <p>A direct connection is a connection in which Hue connects directly to a Drillbit. A ZooKeeper connection is a connection in which Hue communicates with ZooKeeper and ZooKeeper provides Hue with a Drillbit to connect with.</p>	<code>connection_type=zookeeper</code>

drillbits=	Enter the node IP address of the Drillbit that Hue connects with. Only enter a node address if using the "direct" connection_type.	drillbits=10.10.100.2:31010 To list multiple Drillbits, separate each IP address by a comma, as shown: drillbits= <a href="#">10.10.100.2:31010</a> , <a href="#">10.10.100.3:31010</a>  <b>NOTE:</b> Port 31010 is the user port between nodes in a Drill cluster. This port is needed for an external client to connect into the cluster nodes and for the Drill Web Console.
zk_quorum=	Enter the list of ZooKeeper node IP addresses in the ZooKeeper quorum. Only enter the IP addresses for the ZooKeeper quorum if using the "zookeeper" connection_type.	zk_quorum=10.10.100.3:5181, 10.10.100.4:5181, 10.10.100.5:5181
zk_cluster_id=	Enter the name of the Drill cluster that you want Hue to connect to.	zk_cluster_id=dev-drillbits
mechanism=	<p>The type of authentication enabled. Enter one of the following values:</p> <ul style="list-style-type: none"> <li>• None</li> <li>• GSSAPI</li> <li>• Data Fabric-SECURITY</li> </ul> <p>Use None for Plain authentication. Use GSSAPI for Kerberos authentication. Use MAPR-SECURITY for maprsasl.</p> <p>If you set the mechanism to "none" and impersonation is enabled, you must set the username and password to the admin or proxy user that will impersonate Hue end users. You can set these with the user= and password= options.</p> <p>If you set the mechanism to GSSAPI, you must also include the ccache_path= option. For this option, enter the caching location for Kerberos credentials, for example:  ccache_path=/tmp/  hue_krb5_ccache</p> <p> <b>NOTE:</b> See <a href="#">Configure Hue to use Kerberos</a> on page 5177</p> <p>You can set the Drill Kerberos principal and/or Hue impersonation using the option named "options=." See "options=" below.</p>	mechanism=none

user=	<p>If using Plain authentication, enter the username. If using another authentication mechanism, do not enter a value.</p> <p>Set the username to the admin or proxy user that will impersonate Hue end users.</p> <p>If impersonation is disabled, the you can set the user to any user. Hue will connect to Drill as the user specified.</p>	user=mapr
password=	<p>If using Plain authentication, enter the password. If using another authentication mechanism, do not enter a value.</p> <p>Set the password for the admin or proxy user that will impersonate Hue end users.</p> <p>If impersonation is disabled, set the password for the use specified.</p>	password=mapr8
password_script=	<p>Indicates which script to run for the database password when a password is required and the password= option is not set. Enter the location of the script.</p> <p>The following shell script is an example of a password script:</p> <pre>#!/bin/bash case \$1 in drill) echo "password_1";; some-output) echo "password_2";; *) echo "wrong argument" &gt;&amp;2 exit 1;; esac</pre>	password_script='/root/hue_password_script/password_script.sh drill'
options=	<p>Additional options related to impersonation and Kerberos authentication. This option takes the following values:</p> <ul style="list-style-type: none"> <li>• impersonation</li> <li>• principal</li> </ul> <p>Impersonation enables or disables outbound impersonation in Hue. Principal is the Drill service principal when Kerberos authentication is enabled.</p>	<pre>options='{ "impersonation": true, "principal": "mapr/ localhost@REALM" }' options='{ "impersonation": true}' options='{ "impersonation": false}'</pre>

## 2. Add the HTTPFS URL in hue.ini.

The hue.ini file contains a [[[default]]] section in the [hadoop] block under which you can see HDFS configuration options. You must uncomment an option (remove the # character) in the hue.ini file for the option to take effect.

In the [[[default]]] section of the [hadoop] block, enter the IP address of the HTTPFS node as the value for the webhdfs\_url= option, as shown:

```
Use WebHdfs/HttpFs as the communication mechanism.
Domain should be the NameNode or HttpFs host.
Default port is 14000 for HttpFs.
webhdfs_url=https://<httpfs-node-ip-address>:14000/webhdfs/v1
```

## 3. Start the services.

Start/Restart Hue, Drill, and HTTPS to apply the updated configurations, as shown in the following examples:

```
maprcli node services -name hue -action start -nodes
<hue-node-ip-address>

maprcli node services -name drill-bits -action start -nodes
<list-of-drill-node-ip-addresses>

maprcli node services -name httpfs -action start -nodes
<httpfs-node-ip-address>
```

## Run Drill Queries in Hue

Once you have configured Hue and started the services, you can run Drill queries from Hue and visualize your data.

Complete the following steps to run Drill queries in Hue:

1. In your web browser, enter the Hue URL to navigate to the Hue web interface, as shown:

```
http://hue-node-ip-address:8888
```

2. If prompted, enter your user credentials. The Hue interface opens.
3. In the **Query** drop-down, select **Editor > Drill**. The left navigation panel displays the list of schemas available in Drill.
4. Select a schema, for example dfs.default, and then enter a query in the text field.
5. Click the blue play button to execute the query. Query results display.
6. Optionally, you can use the buttons to the left of the query results to visualize the data.

*Configure Hue to use Drill on a MapR-SASL-Secured Cluster*

You can configure Hue to use Drill on a MapR-SASL cluster.

## Procedure

1. Configure Hue to use Drill:

- a) In the `hue.ini`, go to the Drill section, and set the parameters. For example:

```
[librdbms]
[[databases]]
 [[drill]]

 # Name to show in the UI.
 nice_name="Drill"

 # Database backend to use.
 engine=drill

 # Connection type. This can be:
 # 1. direct
 # 2. zookeeper
 connection_type=direct

 # Drillbit address for direct connection.
 drillbits=<node>:31010

 # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY.
 mechanism=MAPR-SECURITY

 # Available options:
 # "impersonation" to enable or disable outbound impersonation.
 # "principal" of Drill service. Used when Kerberos authentication
 is enabled.
 options='{ "impersonation": true, "principal": "mapr/
 <node>@REALM" }'
```

2. Restart Hue to apply the updated configuration:

```
maprccli node services -name hue -action restart -nodes <node>
```

#### *Configure Hue to use Drill on Kerberos-Secured Cluster*

You can configure Hue to use Drill on a Kerberos-secured cluster.

### **Procedure**

1. Configure Hue to use Drill:

- a) In the `hue.ini`, go to the Drill section, and set the parameters. For example:

```
[librdbms]
[[databases]]
 [[drill]]

 # Name to show in the UI.
 nice_name="Drill"

 # Database backend to use.
 engine=drill

 # Connection type. This can be:
 # 1. direct
 # 2. zookeeper
 connection_type=direct

 # Drillbit address for direct connection.
 drillbits=<node>:31010

 # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY.
 mechanism=GSSAPI

 # Available options:
 # "impersonation" to enable or disable outbound impersonation.
 # "principal" of Drill service. Used when Kerberos authentication
 is enabled.
 options='{ "impersonation": true, "principal": "mapr/
 <node>@REALM" }'
```

2. Restart Hue to apply the updated configuration:

```
maprcli node services -name hue -action restart -nodes <node>
```

#### *Configure Hue to use Drill on PAM-Secured Cluster*

You can configure Hue to use Drill on a Pluggable Authentication Modules (PAM) secured cluster.

### **Procedure**

1. Configure Hue to use Drill:

- a) In the `hue.ini`, go to the Drill section, and set the parameters. For example:

```
[librdbms]
 [[databases]]
 [[drill]]

 # Name to show in the UI.
 nice_name="Drill"

 # Database backend to use.
 engine=drill

 # Connection type. This can be:
 # 1. direct
 # 2. zookeeper
 connection_type=direct

 # Drillbit address for direct connection.
 drillbits=<node>:31010

 # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY.
 mechanism=none

 # Username to authenticate with when connecting to the database.
 # Used with plain authentication (mechanism set to "none").
 user=<user>

 # Password matching the username to authenticate with when
 # connecting to the database.
 # Used with plain authentication (mechanism set to "none").
 password=<password>
```

2. Restart Hue to apply the updated configuration:

```
maprcli node services -name hue -action restart -nodes <node>
```

#### *Configure Hue to use Drill on an Unsecured Cluster*

You can configure Hue to use Drill on an unsecure cluster.

### **Procedure**

1. Configure Hue to use Drill:

- a) In the `hue.ini`, go to the Drill section, and set the parameters. For example:

```
[librdbms]
 [[databases]]
 [[drill]]

 # Name to show in the UI.
 nice_name="Drill"

 # Database backend to use.
 engine=drill

 # Connection type. This can be:
 # 1. direct
 # 2. zookeeper
 connection_type=direct

 # Drillbit address for direct connection.
 drillbits=<node>:31010

 # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY.
 mechanism=none
```

2. Restart Hue to apply the updated configuration:

```
maprcli node services -name hue -action restart -nodes <node>
```

#### *Configure Hue to Connect to Drill Using the Drill ODBC Driver*

Describes how to connect Hue to Drill using the Drill ODBC Driver.

Starting in EEP 7.0.0 (Hue 4.6.0.0 and Drill 1.16.1.0), you can install the Drill ODBC driver and then use the driver to connect Hue to Drill. Note that the Drill ODBC Driver is not available for Ubuntu.

For Hue, the ODBC Driver provides better performance than the JDBC Driver. The ODBC Driver is invoked directly from the Python VM of the Hue process whereas Hue must launch a separate Java Gateway process with the JDBC Driver to translate the Python instructions to JVM instructions, which degrades performance.

#### **Prerequisites**

Before you connect Hue to Drill:

- [Install the Drill ODBC Driver on your system.](#)
- Install the unixODBC package on your system:

```
yum install unixODBC
```

- (Optional) Configure the ODBC DSN (Data Source Name) in the `~/.odbc.ini` file, as described in [Apache Drill Docs: Configuring ODBC on Linux](#).

#### **Configuring Hue to Connect to Drill**

To configure Hue to connect to Drill through the Drill ODBC Driver, add the Drill ODBC interpreter entry in the notebook section of `hue.ini` using the `sqlalchemy` interface, as shown in the following example:

```
[notebook]
...
```

```
[[interpreters]]
...
[[[drillodbc]]]
name=Drill ODBC
interface=sqlalchemy
Specify Drill ODBC connection parameters separated by "&".
Ensure that Drill ODBC drivers and unixODBC installed.
options='{ "url": "drill+odbc:///?"<ODBC connection parameters>" }'
```

The following example shows a Hue configuration with the ODBC DSN (Data Source Name) configured in `~/.odbc.ini`. Note that the `DelegationUID=${USER}` property enables outbound impersonation from Hue to Drill.

```
[notebook]
...
[[interpreters]]
...
[[[drillodbc]]]
name=Drill ODBC
interface=sqlalchemy
options='{ "url": "drill+odbc:///?"DSN=MapR Drill 64-bit&DelegationUID=${USER}" }'
```

The following example shows a Hue configuration that uses a Drillbit connection with default security (MapRSASL) enabled:

```
[notebook]
...
[[interpreters]]
...
[[[drillodbc]]]
name=DrillODBC
interface=sqlalchemy
options='{ "url": "drill+odbc:///?"Driver=/opt/mapr/drill/lib/64/
libdrillodbc_sb64.so&ConnectionType=Direct&HOST=node1.cluster.com&PORT=31010
&AuthenticationType=MapRSASL&DelegationUID=${USER}" }'
```

**NOTE:** If you do not use the DSN, you must manually specify the full path to the Drill ODBC Driver, for example:

```
Driver=/opt/mapr/drill/lib/64/libdrillodbc_sb64.so
```

### More information

<https://drill.apache.org/docs/odbc-configuration-reference/>

<https://drill.apache.org/docs/configuring-odbc-on-linux/>

[https://docs.datafabric.hpe.com/62/attachments/JDBC\\_ODBC\\_drivers/DrillODBCInstallandConfigurationGuide.pdf](https://docs.datafabric.hpe.com/62/attachments/JDBC_ODBC_drivers/DrillODBCInstallandConfigurationGuide.pdf)

### Integrate Hue With Spark

#### About this task

**IMPORTANT:** Hue integration with Spark is an experimental feature.

**Procedure**

1. In the [spark] section of the hue.ini file, set the livy\_server\_url parameters to the host and port where the Livy server is running:

```
[spark]
The Livy Server URL.
livy_server_url=https://node10.cluster.com:8998
```

2. To configure Hue to use Spark modes, modify livy.conf (vim /opt/mapr/livy/livy-<version>/conf/livy.conf):

- a) If Spark jobs run on local mode, set the livy.spark.master property:

```
...
What spark master Livy sessions should use.
livy.spark.master = local[*]
...
```

- b) If Spark jobs run on YARN mode, set the livy.spark.master and livy.spark.deployMode properties (client or cluster). For example:

```
...
What spark master Livy sessions should use.
livy.spark.master = yarn
What spark deploy mode Livy sessions should use.
livy.spark.deployMode = cluster
...
```

- c) If Spark jobs run on Standalone mode, set the livy.spark.master property. For example:

```
What spark master Livy sessions should use.
livy.spark.master = spark://ubuntu500:7077
```

- d) If Spark jobs run on Mesos mode, set the livy.spark.master property. For example:

```
What spark master Livy sessions should use.
livy.spark.master = mesos://<mesos-master-node-ip>:5050
```

**NOTE:** Integration of Spark on Mesos with Hue is not supported in cluster deployment mode.

3. If you want to be able to access Hive through Spark in Hue, configure Spark with Hive, and set livy.repl.enableHiveContext to true in livy.conf. For example:

```
...
Whether to enable HiveContext in livy interpreter, if it is true
hive-site.xml will be detected
on user request and then livy server classpath automatically.
livy.repl.enableHiveContext = true
...
```

4. If you plan to use PySpark, you must set the PYTHONPATH environment variable in `livy-env.sh` (`/opt/mapr/livy/livy-<version>/conf/livy-env.sh`):

```
...
export PYTHONPATH=$SPARK_HOME/python/lib/py4j-<version>-
src.zip:$SPARK_HOME/python/:$PYTHONPATH
```

For example:

```
...
export PYTHONPATH=$SPARK_HOME/python/lib/py4j-0.10.7-
src.zip:$SPARK_HOME/python/:$PYTHONPATH
```

5. Ensure that R is installed on the node if you plan to run SparkR. To install R to run SparkR jobs:

**On Ubuntu**

```
sudo apt-get install r-base
```

**On Red Hat / Rocky**

```
sudo yum install R
```

6. Restart the Spark REST Job Server (Livy).

```
maprcli node services -name livy -action restart -nodes <livy node>
```

7. Restart Hue:

```
maprcli node services -name hue -action restart -nodes <hue node>
```

### Integrate Hue with Relational Databases

There are two options for integrating Hue with relational databases:

- SQLAlchemy interpreter interface (*recommended*)
- RDBMS Hue application (*legacy*)

The Hue UI can be integrated to browse and query the following databases:

- MySQL/MariaDB (supported only with the SQLAlchemy interface)
- Oracle
- PostgreSQL
- SQLite

### Integrate with the SQLAlchemy Interpreter Interface

You can connect different databases by adding corresponding entries into the `[notebook]` `[[interpreters]]` section of the `hue.ini`.

In the new section, you need to specify `interface=sqlalchemy` and the SQLAlchemy connection string in the `url` field of the `options` parameter.

Later on this page you can find examples of connection configurations for different relational databases. Additional information about the SQLAlchemy connection options can be found in the following SQLAlchemy documentation:

[Engine Configuration — SQLAlchemy 1.3 Documentation](#)**Integrate with MySQL / MariaDB**

Here is an example of integrating the Hue UI with MySQL / MariaDB:

```
[notebook]
...
[[interpreters]]
...
[[mysql]]
name = MySQL
interface=sqlalchemy
https://docs.sqlalchemy.org/en/latest/dialects/mysql.html
options='{"url": "mysql+mysqlconnector://root:secret@database:3306/hue"}'
```

For information about SQLAlchemy MySQL/MariaDB connector options, see the following article:

[MySQL / MySQL-Connector — SQLAlchemy 1.3 Documentation](#)

**NOTE:** The default SQLAlchemy MySQL dialect is not available in Hue 4.11. Instead, you must use mysql+mysqlconnector.

**Integrate with Oracle**

Before integrating the Hue UI with an Oracle Database, you must install the cx\_Oracle Python module in Hue. To do this, follow steps 1-3 in the [Configure Hue to Store Data in Oracle Database](#) documentation.

For more information about the SQLAlchemy Oracle connector options, see the following article:

[Oracle / cx\\_Oracle – SQLAlchemy 1.3 Documentation](#)

```
[notebook]
...
[[interpreters]]
...
[[oracle]]
name = Oracle
interface=sqlalchemy
options='{"url": "oracle://hue:hue@host:1521/hue"}'
```

**Integrate with PostgreSQL**

Before integrating Hue UI with the PostgreSQL RDBMS, install the psycopg2 Python module. To do this, follow steps 1-3 in the [Configure Hue to Store Data in PostgreSQL](#) documentation.

For more information about SQLAlchemy PostgreSQL connection options, see the following article:

[PostgreSQL / psycopg2 – SQLAlchemy 1.3 Documentation](#)

Here is an example of integrating the Hue UI with PostgreSQL:

```
[notebook]
...
[[interpreters]]
...
[[postgresql]]
name = PostgreSQL
interface=sqlalchemy
options='{"url": "postgresql://hue:hue@host:5432/hue"}'
```

**Integrate with SQLite**

For information about SQLAlchemy SQLite connector options, see the following article:

## SQLite / Pysqlite — SQLAlchemy 1.3 Documentation

Here's an example of integrating the Hue UI with SQLite:

```
[notebook]
...
[[interpreters]]
...
[[[sqlite]]]
 name = SQLite
 interface=sqlalchemy
 options='{"url": "sqlite:///relative/path/to/database/file.db"}'
 # options='{"url": "sqlite:///absolute/path/to/database/file.db"}'
```

### Integrate with the RDBMS Hue Application

Beginning with Hue 4.11:

- The following method is obsolete.
- MySQL integration is not supported in the RDBMS Hue application.

To configure access to a relational database server through the Hue RDBMS application, you need to add your database configuration as an entry in the `[librdbms][[databases]]` section of `hue.ini`. You also need to add a corresponding entry to the `[notebook][[interpreters]]` section with the same section name and the interface parameter set to `rdbms`.

**Table**

Parameter	Used for SQLite?	Value
nice_name	Yes	The nice_name of the current configuration entry.
engine	No	The database back end to use. Available values are: <ul style="list-style-type: none"> <li>• oracle</li> <li>• postgresql</li> <li>• sqlite</li> </ul>
host	No	The IP or hostname of the database server to connect to.
port	No	The ports that the database server is listening to. The default ports are: <ul style="list-style-type: none"> <li>• PostgreSQL:5432</li> <li>• Oracle Express Edition:1521</li> </ul>
name	Yes	The database name to connect to. Leave this property empty if you do not want to connect to a specific database on your database server. For SQLite, this is the path to the database file.
user	No	The user name to authenticate with when connecting to the database server.
password	No	The password for the user name that you will authenticate with when connecting to the database server.
password_script	No	As an alternative to specifying the password explicitly in the <code>hue.ini</code> , you can use the <code>password_script</code> parameter to specify the path to the executable file that will be invoked by Hue to read the password.
options	Yes	For additional options to send to the database server when connecting, see this page: <a href="https://docs.djangoproject.com/en/1.11/ref/databases/">https://docs.djangoproject.com/en/1.11/ref/databases/</a>

Following are examples for connecting to different relational databases.

### Integrate with Oracle

Before integrating Hue UI with an Oracle database, install the `cx_Oracle` Python module in Hue. To do this, follow steps 1-3 in the [Configure Hue to Store Data in Oracle Database](#) documentation.

Here is an example of integrating the Hue UI with Oracle:

```
[librdbms]
...
[[databases]]
...
[[[oracle]]]
nice_name="Oracle DB"
name=example_database
engine=oracle
host=example.host
port=1521
user=example_user
password=example_password

...
[notebook]
...
[[interpreters]]
...
[[[oracle]]]
 name = Oracle
 interface=rdbms
```

### Integrate with PostgreSQL

Before integrating Hue UI with the PostgreSQL RDBMS, install the `psycopg2` Python module. To do this, follow steps 1-3 in the [Configure Hue to Store Data in PostgreSQL](#) documentation.

Here is an example of integrating the Hue UI with PostgreSQL:

```
[librdbms]
...
[[databases]]
...
[[[postgresql]]]
nice_name="PostgreSQL DB"
name=mysqldb
engine=postgresql
host=example.host
port=5432
user=example_user
password=example_password

...
[notebook]
...
[[interpreters]]
...
[[[postgresql]]]
 name = PostgreSQL
 interface=rdbms
```

### Integrate with SQLite

Here is an example of integrating the Hue UI with SQLite:

```
[librdbsms]
...
[[databases]]
...
[[[sqlite]]]
nice_name=SQLite
name=/path/to/sqlite.db
engine=sqlite

...
[notebook]
...
[[interpreters]]
...
[[[sqlite]]]
 name = sqlite
 interface=rdbsms
```

### Use Hue

This section provides information about using Hue, but it does not duplicate the Hue documentation.

You can also refer to the [Hue documentation](#).

This section includes the following topics:

#### Logging in to Hue 4.X

Once Hue is installed and the configuration files have been edited, direct your browser to the IP address where you installed Hue.

#### Procedure

- Open the Hue homepage: `ip_address>:8888`  
The following screen appears:

- Sign in with your username, enter the password mapr and click **Sign in**. You can find your username in the `/opt/mapr/conf/daemon.conf` file.

### Using Hue Welcome Tour

After your first login, you will be introduced to the new features in Hue 4 by the "Welcome Hue 4!" tour.

#### Procedure

1. Start the welcome tour.  
The following screen appears:

2. You are first introduced to the navigation bar:

3. You are introduced to the superuser menu:

4. You are introduced to the left assist panel:

5. You are introduced to the main working zone:

6. You are introduced to the right assist panel:

7. You then come to the end of the tour:

### Getting Started with the Quick Start Wizard (Hue 4.X)

With the Quick Start Wizard you can check configuration, install examples, and create users.

Click on **Hue Administration** in the user menu:

### Step 1: Check Configuration

**Step 2: Examples****Step 3: Users**

**NOTE:** By default, the Hue interface is configured to use PAM for authentication; so you cannot create or import users. For more information, see [Configure Hue Interface Authentication](#).

**User Administration in Hue 4.X**

By default, the Hue interface is configured to use PAM for authentication; so you cannot use the Hue interface to create users or edit their passwords.

**NOTE:** For more information, see [Configure Hue Interface Authentication](#).

This section contains the following topics:

### Changing Your Password

Once you log in, you can change your Hue password.

#### About this task

To change your Hue password, perform the following steps:

#### Procedure

1. Click on your **Username** at the top right of the navigation menu bar and select **Edit Profile** from the drop-down menu. In this example, the username is **mapr**.

The *Hue Users* dialog box opens.

2. Enter your current password in the *Current password* field and enter your new password in the *New Password* field. Retype the password in the *Password confirmation* field.

**User Admin** **Users** Groups Permissions

## Hue Users - Edit user: mapr

**Step 1: Credentials (required)** Step 2: Names and Groups Step 3: Advanced

Username

Password

Password confirmation

Create home directory ☐

[Back](#) [Next](#) [Update user](#)

3. Click **Update user**.

### *Adding Users*

When you click on your username, all users are displayed.

### **About this task**

To create more users, follow these steps:

### **Procedure**

1. Click on your **Username** at the top right of the navigation menu bar and select **Manage Users** from the drop-down menu.

In this example, the username is **mapr**.

2. The *Hue Users - Create user* dialog box opens.

Click **Add user** to finish the process. If you want to assign superuser privileges to the user, click **Next** to proceed to the next screen.

3. Fill in the *Username*, *New Password*, and *Password confirmation* fields.
4. (Optional) Fill in the user's name and email address, and assign a group.

**User Admin** Users Groups Permissions

## Hue Users - Create user

Step 1: Credentials (required) Step 2: Profile and Groups Step 3: Advanced

First name

Last name

Email address

[Back](#) [Next](#) [Add user](#)

5. (Optional) Assign superuser privileges to the user that you just added by checking the *Superuser status* box.

**User Admin** Users Groups Permissions

## Hue Users - Create user

Step 1: Credentials (required) Step 2: Profile and Groups Step 3: Advanced

Active ☒

Superuser status ☐

[Back](#) [Next](#) [Add user](#)

6. Click **Add User**.

### Managing HPE Data Fabric Database Binary Tables in Hue 4.X

You can create and manage HPE Data Fabric Database binary tables in the HBase Browser of the Hue interface.

This section includes the following sections:

*Using the Hbase Browser*

When you open the Hbase Browser, you can view the all the directories and HPE Data Fabric Database binary tables available in the file system.

You can use the HBase Browser to create, edit, and search for HPE Data Fabric Database binary tables. However, you cannot enable, disable, or drop HPE Data Fabric Database binary tables.

**NOTE:** The browser also lists HPE Data Fabric Database JSON tables. However, their appearance is not different from that of HPE Data Fabric Database binary tables. You cannot edit JSON tables.

*Creating a HPE Data Fabric Database Binary Table*

You can create a new HPE Data Fabric Database Binary Table.

**Procedure**

1. In the Hbase Browser, click **New Table**.
2. In the **Table Name** field, provide the full name of the table that you want to create. For example, my\_new\_table.

**Create New Table**

Table Name:

Column Families:  
 [Add a column property](#)

[Add an additional column family](#)

[Cancel](#) [Submit](#)

3. In the *Column Families* field, you can add column families and column properties.
4. Click **Submit**. The table that you created appears in the Hbase Browser:

**Home - Cluster** [Switch Cluster ▾](#)

[Drop](#) [New Table](#)

<input type="checkbox"/>	Table Name
<input type="checkbox"/>	new_table1
<input type="checkbox"/>	my_new_table

No data available in table

 /
 

-  user
-  oozie
-  tmp
-  opt
-  installer
-  apps
-  hbase
-  var

## Starting the Hue Webserver

After you configure the `hue.ini`, you need to start the Hue Webserver and verify that it has started.

### Procedure

1. To start/restart the Hue Webserver, run the following command:

- If Hue is installed on a cluster node (the common use case and recommended practice), run the following command to start the Hue webserver:

```
maprcli node services -name hue -action start -nodes <ip_address>
```

- If Hue is installed on a cluster node (the common use case and recommended practice), run the following command to restart the Hue webserver:

```
maprcli node services -name hue -action restart -nodes <ip_address>
```

- If Hue is installed on an edge node (not recommended), run the following command to start the Hue webserver:

```
/opt/mapr/hue/hue-<version>/bin/hue-server start
```

2. To verify that the Hue webserver started, enter: `lsof -i:8888`

The output from this command should look similar to this:

COMMAND	PID	USER	FD	TYPE	DEVICE	SIZE/OFF	NODE	NAME
python2.6 (LISTEN)	27688	mapr	3u	IPv4	69955314	0t0	TCP	*:ddi-tcp-1
python2.6 (LISTEN)	27691	mapr	3u	IPv4	69955314	0t0	TCP	*:ddi-tcp-1

You can also check Hue webserver logs to verify that Hue webserver started. If the Hue webserver was installed on a *cluster* node or an *edge* node, the log is found here:

```
/opt/mapr/hue/hue-<version>/logs/runcpserver.log
```

## Livy

Apache Livy is primarily used to provide integration between Hue and Spark.

Beginning with EEP 4.0.0, Livy is included as its own package in EEP repositories. Before EEP 4.0.0, Livy was included as `mapr-hue-livy` and released only as a part of Hue. For more information about Livy, see [Apache Livy](#).

This documentation set covers the following topics for Livy:

- [Installing Livy](#) on page 317
- [Configure Livy](#) on page 5223
- [Pre-Upgrade Steps for Livy](#) on page 510
- [Upgrading Livy](#) on page 530
- [Post-Upgrade Steps for Livy](#) on page 548

### Livy Limitations

This page describes some limitations of the HPE Data Fabric implementation of Apache Livy.

Current limitations are as follows:

- The Livy programmatic Java/Scala/Python API is not supported.
- Livy artifacts are not published in the public Maven repository with other HPE Data Fabric artifacts.

### Configure Livy

This topic describes how to configure Livy.

For information about the required package names to configure the Livy server, see [Livy](#) on page 5222.

### Configure Livy with Security

On secure clusters, MapR-SASL authentication, encryption, and impersonation for Livy are enabled by default.

The Livy user interface is available on port 8998. To start the user interface, open a browser, and navigate to the following address:

```
https://<hostname>:8998
```

### Configure Livy on Kerberos

This topic describes how to configure Livy on Kerberos.

To configure Livy on Kerberos, add the following properties to the `livy.conf` file:

```
livy.server.auth.type = kerberos
livy.server.auth.kerberos.principal = HTTP/_HOST@HADOOP.LOCALDOMAIN
livy.server.auth.kerberos.keytab = $KEYTAB
livy.server.launch.kerberos.principal = $USER/_HOST@HADOOP.LOCALDOMAIN
livy.server.launch.kerberos.keytab = $KEYTAB
```

For example:

```
livy.server.auth.type = kerberos
livy.server.auth.kerberos.principal = HTTP/node2.cluster.com@NODE2
livy.server.auth.kerberos.keytab = /opt/mapr/conf/mapr.keytab
livy.server.launch.kerberos.principal = mapr/node2.cluster.com@NODE2
livy.server.launch.kerberos.keytab = /opt/mapr/conf/mapr.keytab
```

### Livy UI on Kerberos

**NOTE:** You can login to the Livy UI on a Kerberos setup only using a web browser configured with SPNEGO.

The other option is to configure multiauth authentication on Kerberized configurations to allow you to login to Livy UI not only with SPNEGO/MapR-Negotiation mechanisms but also with PAM credentials.

### Configure Livy with Custom SSL Encryption

This topic describes how to configure Livy with custom SSL encryption.

### Procedure

1. By default, on a secure cluster, Livy reads the `ssl-server.xml` file and configures SSL from this file.

2. If you want to use custom SSL configuration, add the following properties to the `livy.conf` file:

```
Use this keystore for the SSL certificate and key.
livy.keystore = <path-to-ssl_keystore>

Specify the keystore password.
livy.keystore.password = <password>

Specify the key password.
livy.key-password = <password>
```

### Configure Livy with Spark Modes

This topic describes how to configure Livy with different Spark modes.

Use these steps to configure Livy:

1. Modify the `livy.conf` file (`/opt/mapr/livy/livy-<version>/conf/livy.conf`):
  - a. If Spark jobs run in local mode, set the `livy.spark.master` property:

```
...
What spark master Livy sessions should use.
livy.spark.master = local[*]
...
```

- b. If Spark jobs run in YARN mode, set the `livy.spark.master` and `livy.spark.deployMode` properties (client or cluster). For example:

```
...
What spark master Livy sessions should use.
livy.spark.master = yarn
What spark deploy mode Livy sessions should use.
livy.spark.deployMode = client
...
```

or

```
...
What spark master Livy sessions should use.
livy.spark.master = yarn
What spark deploy mode Livy sessions should use.
livy.spark.deployMode = cluster
...
```

- c. If Spark jobs run in Standalone mode, set the `livy.spark.master` and `livy.spark.deployMode` properties (client or cluster). For example:

```
...
What spark master Livy sessions should use.
livy.spark.master = spark://node:7077
What spark deploy mode Livy sessions should use.
livy.spark.deployMode = client
...
```

or

```
...
What spark master Livy sessions should use.
livy.spark.master = spark://node:7077
What spark deploy mode Livy sessions should use.
livy.spark.deployMode = cluster
...
```

- d. If Spark jobs run in Mesos mode, set the `livy.spark.master` property. For example:

```
What spark master Livy sessions should use.
livy.spark.master = mesos://<mesos-master-node-ip>:5050
```

2. To you want to use impersonation with Livy, set `livy.impersonation.enabled` to `true` in `livy.conf`. For example:

```
If livy should impersonate the requesting users when creating a new
session.
livy.impersonation.enabled = true
```

3. If you want to be able to access Hive through Spark for Livy, you should configure Spark with Hive, and set `livy.repl.enableHiveContext` to `true` in `livy.conf`. For example:

```
...
Whether to enable HiveContext in livy interpreter, if it is true
hive-site.xml will be detected
on user request and then livy server classpath automatically.
livy.repl.enableHiveContext = true
...
```

**NOTE:** If Hive is installed on a cluster and if Spark is configured on Hive, this property is set to `true` by default: `livy.repl.enableHiveContext = true`.

4. To apply the needed changes, restart the Livy service:

```
maprcli node services -name livy -action restart -nodes <livy node>
```

## HPE Data Fabric Streams Clients and Tools

Describes the supported HPE Data Fabric Streams tools and clients.

### HPE Data Fabric Streams Tools

Starting in EEP 8.0.0 and Core 6.2, Kafka 2.6.1.0 supports the following tools and components:

- Kafka Streams API 1.1
- KSQL 6.0.0.0
- Kafka REST 6.0.0.0
- Kafka Connect 10.0.0.0
- Kafka Schema Registry 6.0.0.0
- Spark Streaming

For a complete list of supported versions in each EEP, see [Component Versions for Released Ecosystem Packs](#) on page 7704.

The following points describe the Kafka tools and provide links to additional information:

- [Kafka Streams](#) on page 5243: This tool is a programming library used for creating Java or Scala streaming applications.
- [KSQL](#) on page 5227: This tool is an open source streaming SQL engine that implements continuous, interactive queries.
- [Kafka Schema Registry](#): This tool provides a RESTful interface for storing and retrieving Avro schemas.
- [Kafka REST Proxy](#) on page 5254: This tool is used as a RESTful interface to HPE Data Fabric Streams.
- [Kafka Connect](#) on page 5294: This tool is used to stream data between HPE Data Fabric Streams and other storage systems.

### HPE Data Fabric Streams Clients

HPE Data Fabric Streams client applications can be developed for HPE Data Fabric Streams (as of HPE Data Fabric 5.2.1 with EEP 3.0). The HPE Data Fabric Streams clients are based on distributions of librdkafka that work with HPE Data Fabric Streams.

- HPE Data Fabric Streams C Client - Used to develop HPE Data Fabric Streams applications in C. See [HPE Data Fabric Streams C Applications](#) on page 4006
- HPE Data Fabric Streams Java Client - Used to develop HPE Data Fabric Streams applications in Java. See [HPE Data Fabric Streams Java Applications](#) on page 3964
- HPE Data Fabric Streams Python Client - Used to develop HPE Data Fabric Streams applications in Python. This client is available as of MapR 5.2.1 with EEP 3.0. See [HPE Data Fabric Streams Python Applications](#) on page 4542

**Table**

Core release	EEP Release	Kafka librdkafka version
As of HPE Data Fabric 7.10.0	As of 9.4.0	2.6.0**
As of HPE Data Fabric 7.9.0	As of 9.3.1	2.0.2*
As of HPE Data Fabric 6.0.1	As of 5.0	0.11.3

\*Librdkafka 2.0.2 in core 7.9 is **not** compatible with HPE Data Fabric Stream clients for Python<sup>1</sup> or C#<sup>2</sup> applications. Nodes running Python or C# applications should not be upgraded to HPE Data Fabric 7.9.

\*\*Librdkafka 2.6.0 in core 7.10 is **not** compatible with HPE Data Fabric Stream clients for C#<sup>2</sup> applications. Nodes running C# applications should not be upgraded to HPE Data Fabric 7.10.

<sup>1</sup>[HPE Data Fabric Streams Python Applications](#) on page 4542

<sup>2</sup>[HPE Data Fabric Streams C#/ .NET Applications](#) on page 4553

## KSQL

KSQL is an open-source streaming SQL engine that implements continuous, interactive queries.

Use KSQL to query, read, write, and process data in real-time, at scale, through SQL commands. KSQL interacts directly with the [Kafka Streams API](#), eliminating the need for a Java application.

The KSQL data flow architecture is designed such that the user interacts with the KSQL server and the KSQL server interacts with the HPE Data Fabric Streams server.

## Use Cases

Common use cases include fraud detection, personalization, notifications, real-time analytics, and sensor data and IoT.

## Architecture

A set of KSQL processes run as a cluster, and the KSQL server process completes queries. You can dynamically add more processing capacity by starting more instances of the KSQL server. These instances are fault-tolerant: if one fails, the others continue the work. Queries are launched using the interactive KSQL command line client, which sends commands to the cluster over a REST API. The command line allows you to inspect the available streams and tables, issue new queries, check the status of and terminate running queries.

## KSQL Server

The KSQL server runs the engine that completes KSQL queries. This includes processing, reading, and writing data to and from the target Kafka cluster. KSQL servers form KSQL clusters and can run in containers, virtual machines, and bare-metal machines. You can add and remove servers in a KSQL cluster during live operations to elastically scale processing capacity. You can deploy different KSQL clusters to achieve workload isolation.

## KSQL CLI

You can interactively write KSQL queries through the KSQL command line interface (CLI). The KSQL CLI acts as a client to the KSQL server.

## KSQL Deployment Modes

You can deploy KSQL queries through Interactive or Non-Interactive mode.

### Interactive Mode

In Interactive mode, users interact with the KSQL server through a REST API, such as the KSQL CLI. Interactive mode is useful when users need to write and verify their queries interactively on a shared KSQL cluster. In interactive KSQL clusters, the authenticated KSQL user must have open access to create, read, write, delete topics, and use of any consumer group.

Starting in EEP 7.0.0 (Core 6.2.0 and KSQL 5.2.1.0), Interactive mode is recommended for production.

### Non-Interactive Mode (Headless Mode)

Non-interactive mode supports locked-down or “headless” deployment scenarios where interactive use of the KSQL cluster is disabled, thereby preventing KSQL CLI access. In this mode, you can write queries to an SQL file, which allows for version control, and lock down access to KSQL servers to prevent users from interacting directly with the KSQL cluster.

## KSQL Security

By default, KSQL is secured when installed on secured clusters (clusters secured by the data fabric ticket-based security). See [KSQL Security](#) on page 5228 for additional information.

### For More Information

- [Apache Kafka KSQL](#)
- [Configuring Apache Kafka KSQL Server](#)
- [Apache Kafka Streams](#)

### KSQL Security

Discusses KSQL security topics.

### KSQL Security Overview

By default, KSQL is secure when installed on a secure cluster. A secure cluster is a cluster installed with the default security (MapR-SASL) enabled. Default security provides authentication, encryption, impersonation, and authorization. For encryption, SSL/TLS protocols are supported.

### KSQL Communication Paths

The following image depicts the KSQL communication paths:

The following table lists the supported security mechanisms for the KSQL communication paths:

**NOTE:** Path B does not have a network connection and therefore does not need to be secured. However, impersonation works for this path through KSQL Server.

Security Features	Supported Mechanisms	Communication Paths Secured
<b>Authentication</b>	MapR-SASL (ticket-based security)	<b>D</b> - KSQL Server and ZooKeeper
		<b>A</b> - KSQL client (KSQL CLI/REST API) and KSQL server
		<b>C</b> - KSQL Server and Schema Registry
	Basic (PAM)	<b>A</b> - KSQL client (KSQL CLI/REST API) and KSQL server
		<b>C</b> - KSQL Server and Schema Registry
	Cookie	<b>A</b> - KSQL client (KSQL CLI/REST API) and KSQL server
<b>Encryption</b>	MapR-SASL (ticket-based security)	<b>D</b> - KSQL Server and ZooKeeper
		<b>A</b> - KSQL client (KSQL CLI/REST API) and KSQL server
		<b>C</b> - KSQL Server and Schema Registry
	SSL/TLS	<b>A</b> - KSQL client (KSQL CLI/REST API) and KSQL server
		<b>C</b> - KSQL Server and Schema Registry
<b>Authorization</b>	Based on filesystem permissions	<b>A</b> - KSQL client (KSQL CLI/REST API) and KSQL server
<b>Impersonation</b>	User impersonation	<b>A</b> - KSQL client (KSQL CLI/REST API) and KSQL Server
		<b>B</b> - KSQL Server to Streams for Apache Kafka
		<b>C</b> - KSQL Server and Schema Registry
<b>Auditing</b>	Not supported	--

## Impersonation

See [KSQL Impersonation](#) on page 5232.

## Authorization

See [KSQL Authorization](#) on page 5231.

## Authenticating to KSQL

To authenticate to the KSQL server from the KSQL CLI, include the `--auth` flag and indicate the authentication type for your KSQL environment, for example:

```
ksql --auth MAPRSASL http://<ip-address>:8084
//Note that 8084 is the default port for KSQL.
```

The default value for `--auth` is `MAPRSASL`. The `--auth` flag accepts the following values:

- `--auth BASIC` (For basic or PAM, the system prompts users for a username and password.)
- `--auth MAPRSASL` (For MapR-SASL, a mapr user ticket is used.)
- `--auth NONE` (For none, authentication is disabled.)

To connect the KSQL client to a KSQL server running in a remote cluster, include the `--cluster` option with the remote cluster name, as shown:

```
ksql --cluster my.mapr.cluster https://<ip-address>:8084
```

## KSQL COMMANDS

The KSQL COMMANDS internal topic is used to backup information about KSQL streams, KSQL tables, KSQL persistent queries, and so on. KSQL uses KSQL COMMANDS to restore the KSQL server state in case there is a fault or server restart.

Each KSQL Server cluster has a unique service ID which is provided through the `ksql.service.id` property. By default, the `ksql.service.id` is `_default`. To provide additional security, `ksql.service.id`-specific folders are created in the `ksql-internal-stream` stream.

**NOTE:** The `/apps` directory has only write access to `mapr` user. Therefore, the `/apps/ksql` directory cannot be modified or deleted by any user other than `mapr` user.

KSQL `ksql.service.id`-specific folders are created in the `/apps/ksql/` directory for every KSQL server cluster (represented by `ksql.service.id`).

## Default Stream

KSQL Server provides a default stream for topics when they are being processed. When KSQL Server is not impersonated (non-interactive or interactive+no-impersonation), the KSQL Server default stream is used.

## KSQL Cleanup

The KSQL cleanup feature is integrated to ensure that the underlying KSQL state (such as internal topics) are cleaned up correctly. See [Application Reset Tool](#) on page 5248 for more information.

## Deployment

The Warden service (mapr-warden) manages KSQL Servers in clusters.

**NOTE:** A service ID (`ksql.service.id`) is uniquely created for the KSQL implementation; this means that the user associated with the service ID cannot grant permissions to other users to use the same service ID.

## Cookie Authentication for KSQL

User credentials or challenge strings use cookies to sign requests. After cookies are received on the client side, user credentials or challenge strings are erased from memory. For KSQL, when cookies expire, you have to login again to get the new cookies. Default expiration time for cookies is one week.

## Specify a Custom KSQL Truststore Location on a Secure Cluster

By default, the KSQL CLI uses the truststore file located in `/opt/mapr/conf/ssl_truststore` on a secure cluster; however, you can specify a custom SSL truststore file location through properties set from the command line or in the `ksql-server.properties` file.

### Use the Default Truststore File

To use the default truststore file while working in the KSQL CLI, run:

```
ksql https://node1.cluster.com:8084
```

### Specify a Custom KSQL Truststore from the Command Line

Use the `--truststore` flag with the directory location where the SSL truststore file is located and the `--truststore-password` with the truststore password, as shown in the following example:

```
ksql https://node1.cluster.com:8084 --truststore /opt/mapr/conf/ssl_truststore2 --truststore-password test123
```

## For More Information

- [Apache Kafka KSQL](#)
- [Configuring Apache Kafka KSQL Server](#)

### *KSQL Authorization*

Describes authorization for Kafka KSQL.

In secure clusters, authorization is enabled by default. In non-secure clusters, authorization is disabled by default.

You can enable or disable authorization for KSQL in the `/opt/mapr/ksql/ksql-<version>/etc/ksql/ksql-server.properties` file through the following option:

```
authorization.enable=[true|false]
```

## Permissions

Permissions grant or deny access to users that run commands and maintain background processes that interact with KSQL internal data and structure information, such as persistent queries, tables, streams,

and server configuration. *Read* permission grants users and groups access to `FETCH`, `SHOW`, and `DESCRIBE`. *Modify* permission grants users and groups access to `ADD`, `UPDATE`, and `REMOVE`.

Each user or group in a cluster can have no permissions, *read* permission, *modify* permission, or both *read* and *modify* permission to the KSQL service. By default all Data Fabric cluster users have both *read* and *modify* permissions.

Internally, the authorization filter is based on *consumeperms* and *produceperms* for the KSQL Kafka store internal stream (`/apps/ksql/<service.id>/ksql-commands:ksql-authorization-auxiliary-topic`). *Consumeperms* correspond to the KSQL service *read* permissions. *Produceperms* correspond to the KSQL service *modify* permissions. These permissions can be changed by modifying the ACE of *produceperms* and *consumeperms* for `/apps/ksql/<service.id>/ksql-commands:ksql-authorization-auxiliary-topic`.

The following sections describe KSQL statements that require *read* and *modify* access.

### Statements that Require Read Access

<b>DESCRIBE [EXTENDED] ...</b>	List the columns in a stream or table along with its attributes and information.
<b>DESCRIBE FUNCTION ...</b>	Provides a description of a function including an input parameters and the return type.
<b>EXPLAIN ...</b>	Show the execution plan for a SQL expression or, given the ID of a running query, show the execution plan plus additional runtime information and metrics.
<b>PRINT ...</b>	Print the contents of Kafka topics to the KSQL CLI.
<b>SELECT ...</b>	Selects rows from a KSQL stream or table.
<b>SHOW ...</b>	List functions, streams, tables, queries, properties.
<b>SHOW TOPICS &lt;MAPR_STREAM&gt;</b>	List topics.

### Statements that Require Modify Access

<b>CREATE STREAM TABLE ... WITH (...)</b>	Create a new stream or table with the specified columns and properties.
<b>CREATE STREAM TABLE ... [WITH (...)] AS SELECT ...</b>	Create a new stream or table and continuously write the result of the <code>SELECT</code> query into the stream.
<b>INSERT INTO ... SELECT ...</b>	Stream the result of the <code>SELECT</code> query into an existing stream and its underlying topic.
<b>INSERT INTO ... VALUES ...</b>	Produce a row into an existing stream or table and its underlying topic based on explicitly specified values.
<b>DROP STREAM TABLE [IF EXISTS] ...</b>	Drops an existing stream or table.
<b>DROP STREAM TABLE [IF EXISTS] ... DELETE TOPIC</b>	Drops an existing stream or table and deletes the underlying topic.
<b>TERMINATE ...</b>	Terminate a persistent query.

#### *KSQL Impersonation*

Describes impersonation for Kafka KSQL.

The HPE Data Fabric Event Store implementation performs impersonation on behalf of KSQL CLI users in KSQL Servers. Impersonation authorizes the impersonated user to perform permission-sensitive operations.

**Requirement:** For impersonation to work, KSQL authentication must be enabled; otherwise, the server will not start and the system will return an error. When authentication is enabled, all commands run as the authenticated user instead of the KSQL principal. The KSQL principal is the user that started KSQL server.

You can enable or disable impersonation for KSQL in the `/opt/mapr/ksql/ksql-<version>/etc/ksql/ksql-server.properties` file through the following option:

```
impersonation.enable=[true|false]
```

### Related concepts

[KSQL Authorization](#) on page 5231

Describes authorization for Kafka KSQL.

### KSQL Configuration

Set KSQL configuration and security parameters in the `ksql-server.properties` file. The default port for KSQL is 8084.

### Configuring KSQL to Run in Non-Interactive (Headless) Mode

To run KSQL in non-interactive mode, set the parameters shown and then start KSQL.

**NOTE:** Note that the `ksql.default.stream` parameter is optional, but recommended. This parameter sets the default stream to consume from and send the messages to. The default stream is used if the topic name does not include the stream name. For example, if a message is sent to `exampleTopic` and this parameter is set to `/exampleStream`, then the message is sent to `/exampleStream:exampleTopic`.

Set the following properties in the `/opt/mapr/ksql/ksql-<version>/etc/ksql/ksql-server.properties` file:

```
ksql.command.topic.suffix=commands
ksql.service.id=app2
listeners=http://localhost:8084
ksql.default.stream=/sample-stream
```

Start KSQL:

```
$ KSQL_INSTALL_DIR/bin/ksql-server-start /opt/mapr/ksql/ksql-<version>/etc/ksql/ksql-server.properties --queries-file some-queries-file.sql
```

### Configuring KSQL to Run in Interactive Mode

The following example shows the configuration parameters that you must set in the `ksql-server.properties` file to run KSQL in interactive (distributed) mode:

```
ksql.command.topic.suffix=commands
ksql.service.id=app2
listeners=http://192.168.121.73:8084
ksql.default.stream=/sample-stream
```

**NOTE:** You must set the `listeners` parameter to an actual IP address.

### For more information

- For installation information, see [Installing KSQL](#) on page 307.
- For Apache Kafka information, see the [Apache Kafka Streams API](#), [Apache Kafka Producer Clients](#), and the [Apache Kafka Consumer Clients](#).

*KSQL Configuration Parameters*

Set the KSQL configuration parameters in the `/opt/mapr/ksql/ksql-<version>/config/ksql-server.properties` file. For more information about configuration parameters, see [KSQL Configuration Parameter Reference](#).

The following table describes some KSQL configuration parameters:

Parameter	Description
<code>ksql.default.stream</code>	The stream that is used when a topic is used without a stream name.
<code>ksql.schema.registry.enable</code>	Flag for enabling Avro format support with Schema Registry. Default value: false
<code>ksql.schema.registry.service.id</code>	Indicates the ID of the schema registry service. Default value: default_
<code>ksql.schema.registry.discovery.timeout</code>	The timeout (in milliseconds) for requests to Schema Registry URL storage. Default value: 60000
<code>ksql.schema.registry.discovery.retries</code>	The number of retries for Schema Registry URL discovery. Default value: 6
<code>ksql.schema.registry.discovery.interval</code>	The interval (in milliseconds) between retries for Schema Registry URL discovery. Default value: 15000

#### *KSQL Security Parameters*

Describes KSQL security parameters.

Security parameters provide an authentication, encryption, and impersonation layer between the KSQL clients and the KSQL Server. In secure clusters, KSQL is secured by default.

**Requirement:** Before you configure KSQL security parameters, verify that an `ssl_keystore` and an `ssl_truststore` file have been created.

The following table describes KSQL security parameters:

Parameter	Description	Type	Default
<code>ksql.schema.registry.maprsasl.auth</code>	Enable MapR Sasl authentication for Avro format with Schema Registry.	boolean	false
<code>authentication.cookie.expiration</code>	Authentication cookie expiration time in seconds.	long	7200 (2 hours)
<code>authorization.enable</code>	Set 'true' or 'false' to enable or disable authorization for KSQL service. See <a href="#">KSQL Authorization</a> on page 5231.	boolean	false
<code>authentication.enable</code>	Whether or not to enable authentication.	boolean	false
<code>impersonation.enable</code>	Whether or not to enable impersonation. If disabled, all manipulation will be performed from the admin of cluster user. See <a href="#">KSQL Impersonation</a> on page 5232.	boolean	false
<code>listeners</code>	Comma-separated list of listeners that listen for API requests over either HTTP or HTTPS. Each listener must include the protocol, hostname, and port. For example: <a href="http://localhost:8084">http://localhost:8084</a>	list	none
<code>ssl.cipher.suites</code>	A list of SSL cipher suites. This list is a comma-separated list. Leave blank to use Jetty's default.	list	none

Parameter	Description	Type	Default
ssl.cipher.suites.exclude	A list of disabled SSL cipher suites. This is a comma-separated list. Leave blank to use Jetty's default.	list	<ul style="list-style-type: none"> <li>• TLS_DHE.*</li> <li>• TLS_EDH.*</li> <li>• .DES.</li> <li>• .MD5.</li> <li>• .RC4.</li> </ul>
ssl.client.auth	Specifies whether or not to acquire the HTTPS client to authenticate via the server's trust store. <i>This option is not available in KSQL 6.0.</i>	boolean	false
ssl.client.authentication	Specifies whether or not to acquire the HTTPS client to authenticate via the server's trust store. Possible values are NONE, REQUESTED, and REQUIRED. <i>This option is available in KSQL 6.0.</i>	string	none
ssl.disabled.protocols	The list of SSL protocols that will not be accepted by clients. This is a comma-separated list.	list	<ul style="list-style-type: none"> <li>• SSLv3</li> <li>• TLSv1.0</li> </ul>
ssl.enabled.protocols	The list of SSL protocols that can be accepted from clients. The list is a comma-separated list. Leave blank to use Jetty's defaults.	list	empty
ssl.endpoint.identification.algorithm	The endpoint identification algorithm to validate the server hostname using the server certificate. IMPORTANT: Jetty requires that the key's CN, stored in the keystore, must match the FQDN if ssl_endpoint_identification_algorithm=https. Leave blank to use Jetty's default.	string	none
ssl.key.password	The password of the private key in the keystore file. This parameter should be taken from the /opt/mapr/conf/ssl-client.xml file. If this parameter is not set, the property value is obtained from the ssl-client.xml file.  <b>NOTE:</b> If the ssl-client.xml file is changed, restart KSQL.	string	empty
ssl.keymanager.algorithm	The algorithm used by the key manager factory for SSL connections. Leave blank to use Jetty's default.	string	empty
ssl.keystore.location	Location of the keystore file. This parameter should be taken from the /opt/mapr/conf/ssl-client.xml file. If this parameter is not set, the property value is obtained from the ssl-client.xml file.  <b>NOTE:</b> If the ssl-client.xml file is changed, restart KSQL.	string	empty
ssl.keystore.password	The store password for the keystore file. This parameter should be taken from the /opt/mapr/conf/ssl-client.xml file. If this parameter is not set, the property value is obtained from the ssl-client.xml file.  <b>NOTE:</b> If the ssl-client.xml file is changed, restart KSQL.	string	empty

Parameter	Description	Type	Default
ssl.keystore.type	The type of keystore file.	string	JKS
ssl.protocol	The SSL protocol used to generate the SslContextFactory.	string	TLS
ssl.provider	The SSL security provider name. Leave blank to use Jetty's default.	string	none
ssl.trustmanager.algorithm	The algorithm used by the trust manager factory for SSL connections. Leave blank to use Jetty's default.	string	none
ssl.truststore.location	Location of the trust store. Required only to authenticate HTTPS clients.	string	empty
ssl.truststore.password	The store password for the trust store file.	string	empty
ssl.truststore.type	The type of trust store file.	string	JKS
ssl.trustallcerts.enable	Set to true if you want to disable certificates verification.	boolean	false
headers.file	The option is used to specify the XML file that contains security and custom headers. The headers will be added to a response by the Jetty server.	string	empty

**Related reference**

[KSQL Security](#) on page 5228

Discusses KSQL security topics.

**KSQL Reference**

KSQL-specific commands are commands for setting your KSQL configuration, exiting the CLI, and so on.

Run the KSQL with --help to see the available options.

```
./bin/ksql --help
```

CLI commands include:

- help
- clear
- output
- output <format>
- history
- version
- exit

KSQL is started by issuing the `./bin/ksql` command and the KSQL statements are run in the KSQL command line once it starts.

**KSQL Statements****General Syntax**

KSQL is started by issuing the `./bin/ksql` command and the KSQL statements are run in the KSQL command line once it starts.

KSQL statements must be terminated with a semicolon (;).

For multi-line statements:

- In the CLI, you use a back-slash (\) to indicate continuation of a statement on the next line.
- Do not use backslashes (\) for multi-line statements in .sql files.

## CREATE STREAM

### CREATE STREAM WITH clause

Creates a new stream with the specified columns and properties.

```
CREATE STREAM stream_name ({ column_name data_type } [, ...])
 WITH (property_name = expression [, ...]);
```

### CREATE STREAM WITH clause and AS SELECT

Creates a new stream with the specified columns and properties along with the corresponding HPE Data Fabric Streams topic.

```
CREATE STREAM stream_name
 [WITH (property_name = expression [, ...])]
 AS SELECT select_expr [, ...]
 FROM from_item [, ...]
 [WHERE condition]
 [PARTITION BY column_name]
```

## CREATE TABLE

### CREATE TABLE WITH clause

Creates a new KSQL table with the specified columns and properties.

```
CREATE TABLE table_name ({ column_name data_type } [, ...])
 WITH (property_name = expression [, ...]);
```

### CREATE TABLE WITH clause and AS SELECT

Creates a new stream with the specified columns and properties along with the corresponding HPE Data Fabric Streams topic and stream.

```
CREATE TABLE table_name
 [WITH (property_name = expression [, ...])]
 AS SELECT select_expr [, ...]
 FROM from_item [, ...]
 [WINDOW window_expression]
 [WHERE condition]
 [GROUP BY grouping_expression]
 [HAVING having_expression];
```

## DESCRIBE

### DESCRIBE

Lists the columns in a stream or table along with their data type and other attributes.

```
DESCRIBE (stream_name|table_name);
```

**DESCRIBE EXTENDED**

Displays DESCRIBE information with additional runtime statistics, HPE Data Fabric Streams topic details, and the set of queries that populate the table or stream.

```
DESCRIBE [EXTENDED] (stream_name|table_name);
```

**EXPLAIN****EXPLAIN**

Shows the execution plan for a SQL expression or, given the ID of a running query, shows the execution plan plus additional runtime information and metrics.

```
EXPLAIN (sql_expression|query_id);
```

**DROP STREAM****DROP STREAM**

Drops an existing stream

```
DROP STREAM stream_name;
```

**DROP TABLE****DROP TABLE**

Drops an existing table.

```
DROP TABLE table_name;
```

**PRINT****PRINT**

Prints topic contents to the KSQL CLI.

**NOTE:** SQL grammar defaults to uppercase formatting. To print topics containing lower-case characters, use quotations.

```
PRINT qualified_name (FROM BEGINNING)? ((INTERVAL | SAMPLE) number)?
```

**Print Example**

```
ksql> print '/sample-stream:streams-pipe-input' FROM BEGINNING;
Format:STRING
3/16/18 1:04:39 AM EET , 1 , record1
3/16/18 1:04:39 AM EET , 5 , record5
3/16/18 1:04:39 AM EET , 6 , record6
3/19/18 4:22:51 PM EET , null , Hello
3/19/18 4:23:05 PM EET , null , Hello2
```

**SELECT**

**SELECT**

Selects rows from a KSQL stream or table. The result of this statement is not persisted in a topic and is only printed out in the console. To stop the continuous query in the CLI press Ctrl-C.

```
SELECT select_expr [, ...]
FROM from_item
[LEFT JOIN join_table ON join_criteria]
[WINDOW window_expression]
[WHERE condition]
[GROUP BY grouping_expression]
[HAVING having_expression]
EMIT CHANGES
[LIMIT count];
```

**SELECT CAST expression type**

Casts an expression's type to a new type.

```
CAST (expression AS data_type);
```

```
SELECT userid, CONCAT(CAST(COUNT(*) AS VARCHAR), '_HELLO')
FROM pageviews
WINDOW TUMBLING (SIZE 20 SECONDS)
GROUP BY userid
EMIT CHANGES;
```

**SELECT LIKE operator**

The LIKE operator is used for prefix or suffix matching. Currently KSQL supports %, which represents zero or more characters.

```
column_name LIKE pattern;
```

```
SELECT userid
FROM pageviews
WHERE userid LIKE '%4'
EMIT CHANGES;
```

**SHOW TOPICS****SHOW TOPICS**

Prints topic information for all topics for the default stream (specified by ksql.default.stream). If the default stream is not specified, then an exception is thrown.

```
SHOW TOPICS;
```

**SHOW TOPICS <stream\_name>**

Prints topic information for all topics from the specified stream. For example: /sample-stream

```
SHOW TOPICS '/sample-stream';
```

**SHOW STREAMS**

**SHOW STREAMS**

List the defined streams.

```
SHOW | LIST STREAMS;
```

**SHOW TABLES****SHOW TABLES**

List the defined TABLES.

```
SHOW | LIST TABLES;
```

**SHOW QUERIES****SHOW QUERIES**

List the running persistent queries.

```
SHOW | LIST QUERIES;
```

**SHOW PROPERTIES****SHOW PROPERTIES**

Lists the configuration setting that are currently in effect.

```
SHOW PROPERTIES;
```

**TERMINATE****TERMINATE**

Terminate a persistent query. Persistent queries run continuously until they are explicitly terminated

```
TERMINATE query_id;
```

*Scalar Functions*

The following are scalar functions for KSQL.

**Table**

Function	Example	Description
ABS	ABS(col1)	Absolute value of a value.
CEIL	CEIL(col1)	Ceiling of a value.
CONCAT	CONCAT(col1, '_hello')	Concatenate two strings.
EXTRACTJSONFIELD	EXTRACTJSONFIELD(message, '\$.log.cloud')	Given a string column in JSON format, extract the field that matches.
ARRAYCONTAINS	ARRAYCONTAINS(['1, 2, 3'], 3)	Given a JSON or AVRO array, checks if a search value is contained in it.
FLOOR	FLOOR(col1)	Floor of a value.
LCASE	LCASE(col1)	Convert a string to lowercase.
LEN	LEN(col1)	Length of a string.

**Table (Continued)**

Function	Example	Description
RANDOM	RANDOM()	Returns a random DOUBLE value between 0 and 1.0
ROUND	ROUND(col1	Round a value to the nearest BIGINT value.
STRINGTOTIMESTAMP	STRINGTOTIMESTAMP(col1, 'yyyy-MM-dd HH:mm:ss.SSS')	Converts a string value in the given format into the BIGINT value representing the timestamp.
SUBSTRING	SUBSTRING(col1, 2, 5)	Returns the substring with the start and end indices.
TIMESTAMP TO STRING	TIMESTAMP TO STRING(ROWTIME, 'yyyy-MM-dd HH:mm:ss.SSS')	Converts a BIGINT timestamp value into the string representation of the timestamp in the given format.
TRIM	TRIM(col1)	Trim the spaces from the beginning and the end of the string.
CASE	CASE(col1)	Convert a string to uppercase.

### Aggregate Functions

The following are aggregate functions for KSQL.

**Table**

Function	Example	Description
COUNT	COUNT(col1)	Counts the number of rows.
MAX	MAX(col1)	Returns the maximum value for a given column and window.
MIN	MIN(col1)	Returns the minimum value for a given column and window.
SUM	SUM(col1)	Sums the column values.
TOPK	TOPK(col1, K)	Returns the TopK values for the given column and window.
TOPKDISTINCT	TOPKDISTINCT(col1, K)	Returns the distinct TopK values for the given column and window.

### Pipe Code Sample

Provides sample code for a Pipe example.

The following is a Pipe code sample that moves an inputTopic to an outputTopic:

```
ksql> CREATE STREAM stream3 (message varchar) WITH (kafka_topic='/
sample-stream:inputTopic', value_format='DELIMITED');

ksql> CREATE STREAM stream4 WITH (kafka_topic='/
sample-stream:streams-pipe-output1', value_format='DELIMITED') AS SELECT *
FROM stream3;
```

### KSQL Demo

The following demo example creates a stream, performs a non-persistent query, and a persistent query.

## Setup

Complete the following steps to prepare your environment for querying:

1. Create a default stream using /sample-stream:

```
maprcli stream create -path /sample-stream
 -produceperm p -consumeperm p -topicperm p
```

2. Run the following script to generate test data that writes to an HPE Data Fabric Streams topic:

```
./bin/ksql-datagen quickstart=pageviews format=delimited
topic=/sample-stream:pageviews maxInterval=10000
```

3. Run KSQL CLI and create a KSQL table:

```
> ./bin/ksql http://<ksql-server>:8084
ksql> CREATE STREAM pageviews
 (viewtime BIGINT,
 userid VARCHAR,
 pageid VARCHAR)
 WITH (KAFKA_TOPIC='/sample-stream:pageviews',
 VALUE_FORMAT='DELIMITED');

ksql> CREATE TABLE PAGEVIEWS_TABLE
 WITH(KAFKA_TOPIC='/sample-stream:pageviews_table')
 AS
 SELECT userid,
 MAX(viewtime)
 FROM pageviews
 GROUP BY userid;
```

4. Run the SHOW TABLES command to list your KSQL tables:

```
ksql> SHOW TABLES;
```

## Run a Non-persistent Query

For a non-persistent query in KSQL 6.0, run:

```
ksql> SELECT * FROM PAGEVIEWS_TABLE WHERE userid='User_1';
```

## Run a Persistent Query

For a persistent query, do the following:

1. Create the topic, /sample-stream:input-topic:

```
maprcli stream topic create -path /sample-stream -topic input-topic
```

2. Create a KSQL input stream:

```
ksql> CREATE STREAM stream1 (message varchar) WITH
 (kafka_topic='/sample-stream:input-topic' ,
 value_format='DELIMITED');
```

3. Create persistent query with filtering:

```
ksql> CREATE STREAM stream2
 WITH (kafka_topic='/sample-stream:output-topic' ,
 value_format='DELIMITED')
 AS SELECT * FROM stream1 WHERE LEN(message) > 2;
```

4. List your queries:

```
ksql> SHOW QUERIES;
```

5. Run the provided sample code for the console producer:

```
/opt/mapr/kafka/kafka-<version>/bin/kafka-console-producer.sh
--broker-list fake.server.id:9092 --topic /sample-stream:input-topic
```

6. Run the provided sample code for the console consumer:

```
/opt/mapr/kafka/kafka-<version>/bin/kafka-console-consumer.sh
--bootstrap-server fake.server.id:9092
--topic /sample-stream:output-topic
```

7. Produce some data:

```
>Hi
>Hello
>No
>Yes
```

8. Get the next results:

```
Hello
Yes
```

### Auxiliary Scripts Location

The sample code for `kafka-console-producer.sh` and `kafka-console-consumer.sh` is packaged with Kafka. Once Kafka is installed, you can find them at:

```
/opt/mapr/kafka/kafka-<version>/bin/
```

### Kafka Streams

Kafka Streams is a programming library used for creating Java or Scala streaming applications and, specifically, building streaming applications that transform input topics into output topics.

Kafka Streams allows you to build moderately complex operational streaming applications faster by offloading common functions such as failure recovery, joins and enrichment, and aggregations and windowing.

Kafka Streams application is a distributed Java application that is launched with one or more Kafka Streams application instances. Kafka Streams applications can be built using the KStream library. A KStream application instance is required to be provided with an `application.id` property. The `application.id` property uniquely identifies the Kafka Streams distributed application.

**ATTENTION:** The Kafka Streams application must always be launched as the same user.

## Architecture

An application that uses the Kafka Streams API is a normal Java application. Package, deploy, and monitor it like you would do for any other Java application. There is no need to install separate processing clusters or similar special-purpose and expensive infrastructure.

**NOTE:** You can run one or more instances of your application. They run independently but will automatically discover each other and collaborate. In addition, you can elastically add and remove application instances during live operations. If one instance dies, another instance continues where that instance left off.

The following diagram shows an application that is running three (3) application instances.

## For More Information

[Apache Kafka Streams](#)

### Kafka Streams Configuration

Describes how to configure Kafka Streams.

### Kafka Streams Configuration

To configure Kafka Streams, set the following parameters in the Java API StreamsConfig instance:

- (Optional) Set the HPE Data Fabric Streams `streams.default.stream` configuration parameter. See [Apache Kafka Streams: Configuring a Streams Application](#) for more information about all of the configuration parameters, required and optional.

The default stream is used to consume from and send the messages to, if the topic name does not include the stream name. For example, if a message is sent to `exampleTopic` and this parameter is set to `/exampleStream`, then the message will be sent to `/exampleStream:exampleTopic`.

**NOTE:** If the default stream option is not set and the topic name is specified without a stream name, an exception is thrown.

- Set the Apache Kafka Streams `application.id` configuration parameter. See [Apache Kafka Streams: Configuring a Streams Application](#) for more information about all of the configuration parameters, required and optional.

#### For more information

- For installation information, see [Installing Kafka Streams](#) on page 308.
- For Apache Kafka Streams information, see [Apache Kafka Streams: Configuring a Streams Application](#).

#### Supported Apache Kafka Streams APIs

Specifies the supported and not supported Apache Kafka Streams APIs.

#### Supported APIs

MapR Kafka Streams uses the same APIs as Apache Kafka Streams. Behavior for HPE Data Fabric Streams is the same as for Apache Kafka Streams. See [Apache Kafka Streams documentation](#).

#### Not Supported APIs

The following stream methods in the `StreamsBuilder` class are not supported:

- `<K,V> KStream<K,V> stream(java.util.regex.Pattern topicPattern)`
- `<K,V> KStream<K,V> stream(java.util.regex.Pattern topicPattern, Consumed<K,V> consumed)`

Use the following stream method instead:

- `<K,V> KStream<K,V> stream(java.util.Collection<java.lang.String> topics)`

#### Running a Kafka Streams Java App

Describes how to set up and run a Kafka Streams Java application.

#### Setup

To set up your project, add the required dependencies to the `pom.xml` file, as shown in the example. Note that the versions you use may differ from the versions shown in the example. Version numbers typically change with new releases.

Maven artifacts are published to <https://repository.mapr.com/maven/>. You can also refer to [Maven Artifacts for the HPE Data Fabric](#) on page 5559 for dependency versions.

#### Example pom.xml

The following example shows the dependencies you must add to `pom.xml`.

```
<repository>
 <id>mapr-releases</id>
 <url>https://repository.mapr.com/maven/</url>
</repository>

...
<dependency>
 <groupId>org.apache.kafka</groupId>
 <artifactId>kafka-streams</artifactId>
```

```
<version>3.6.1.0-ee-930</version>
</dependency>
```

### Running a Kafka Streams App on a Cluster

To run a Kafka Streams Java application on a cluster:

1. Copy the <Kafka Streams Java application>.jar file to an arbitrary folder on your cluster.
2. Run the following shell command on your cluster:

```
java -cp "$(mapr clientclasspath):<path to Kafka Streams application
jar>" <Kafka Streams application main class>
```

### Pipe Code Sample

Provides sample code for a Pipe example.

The following is a Pipe code sample that moves records from an inputTopic to an outputTopic:

```
...
final StreamsBuilder builder = new StreamsBuilder();
KStream<String,String> source = builder stream(inputTopic);
source.to(outputTopic);
final Topology topology= builder.build();
final KafkaStreams streams=new KafkaStreams(topology, props);
...
streams.start();
...
```

### Kafka Streams Demo

Provides a Kafka Streams demo example that creates a stream and topics and runs the WordCountDemo class code. The sample code produces and consumes messages.

1. Create the a stream named /sample-stream:

```
maprcli stream create -path /sample-stream -produceperm p -consumeperm
p -topicperm p
```

2. Create word-count-input and word-count-output topics:

```
maprcli stream topic create -path /sample-stream -topic word-count-input
maprcli stream topic create -path /sample-stream -topic word-count-output
```

3. Build the word count application and copy its JAR file to your cluster.
4. Run the WordCountDemo class.
  - For Kafka 2.1.1 and earlier, run:

```
java -cp "$(mapr clientclasspath):<Word Count Application Name>.jar"
WordCountDemo
```

- For Kafka 2.6.1, run:

```
java -cp "$(mapr clientclasspath):/opt/mapr/kafka/kafka-<version>/libs/
kafka-eventstreams<version>.jar:<Word Count Application Name>.jar"
WordCountDemo
```

5. Run the console producer:

```
/opt/mapr/kafka/kafka-<version>/bin/kafka-console-producer.sh
--broker-list fake.server.id:9092
--topic /sample-stream:word-count-input
```

6. Run the console consumer:

```
/opt/mapr/kafka/kafka-<version>/bin/kafka-console-consumer.sh
--bootstrap-server fake.server.id:9092
--topic /sample-stream:word-count-output
--property print.key=true
```

7. Produce some input with the console producer:

```
>word27 word28 word27 word29
```

8. Get the following output:

```
word28 1
word27 2
Word29 1
```

### WordCountDemo Class Code

```
import org.apache.kafka.common.serialization.Serdes.StringSerde;
import org.apache.kafka.common.serialization.Serdes;
import org.apache.kafka.common.utils.Bytes;
import org.apache.kafka.streams.KafkaStreams;
import org.apache.kafka.streams.StreamsBuilder;
import org.apache.kafka.streams.StreamsConfig;
import org.apache.kafka.streams.Topology;
import org.apache.kafka.streams.kstream.*;
import org.apache.kafka.streams.state.KeyValueStore;

import java.util.Arrays;
import java.util.Locale;
import java.util.Properties;
import java.util.concurrent.CountDownLatch;

public class WordCountDemo {

 public static final String INPUT_TOPIC = "/
sample-stream:word-count-input";
 public static final String OUTPUT_TOPIC = "word-count-output"; //
Default stream will be used

 public static final String DEFAULT_STREAM = "/sample-stream";

 public static final String APP_ID = "app-id";
```

```

 public static void main(String[] args) {
 Properties props = new Properties();
 props.put(StreamsConfig.APPLICATION_ID_CONFIG, APP_ID);
 props.put(StreamsConfig.DEFAULT_KEY_SERDE_CLASS_CONFIG,
StringSerde.class);
 props.put(StreamsConfig.DEFAULT_VALUE_SERDE_CLASS_CONFIG,
StringSerde.class);

 props.put(StreamsConfig.COMMIT_INTERVAL_MS_CONFIG, 500); // Put
attention to this property
 props.put(StreamsConfig.STREAMS_DEFAULT_STREAM_CONFIG,
DEFAULT_STREAM);

 final StreamsBuilder builder = new StreamsBuilder();

 KStream<String, String> wordCountStream = builder.<String,
String>stream(INPUT_TOPIC)
 .flatMapValues(value ->
Arrays.asList(value.toLowerCase(Locale.getDefault()).split("\\W+")))
 .groupBy((key, value) -> value)
 .count(Materialized.<String, Long, KeyValueStore<Bytes,
byte[]>>as("counts-store"))
 .mapValues(x -> x.toString())

 .toStream();

 wordCountStream.to(OUTPUT_TOPIC, Produced.with(Serdes.String(),
Serdes.String()));

 final Topology topology = builder.build();
 final KafkaStreams streams = new KafkaStreams(topology, props);
 final CountDownLatch latch = new CountDownLatch(1);

 // attach shutdown handler to catch control-c
 Runtime.getRuntime().addShutdownHook(new
Thread("streams-shutdown-hook") {
 @Override
 public void run() {
 streams.close();
 latch.countDown();
 }
 });

 try {
 streams.start();
 latch.await();
 } catch (Throwable e) {
 e.printStackTrace();
 System.exit(1);
 }
 System.exit(0);
 }
 }

```

**NOTE:** The `kafka-console-producer.sh` and `kafka-console-consumer.sh` scripts are part of the **mapr-kafka** package.

### Application Reset Tool

This tool allows you to reset an application and force it to reprocess its data from scratch by using the application reset tool. This tool can be useful for development and testing, or when fixing bugs.

## Description

The application reset tool (ART) handles the Kafka Streams user topics (input, output, and intermediate topics) and internal topics differently when resetting the application.

The application reset tool does the following for each topic type:

- Input topics: Reset to the beginning of the topic. This means that it sets the application's committed consumer offsets for all partitions to each partition's earliest offset (for consumer group `application.id`).
- Intermediate topics: Skip to the end of the topic, i.e., set the application's committed consumer offsets for all partitions to each partition's `logSize` (for consumer group `application.id`).
- Internal topics: Delete the internal topic (this automatically deletes any committed offsets).

The application reset tool does not do the following:

- Reset output topics of an application. If any output (or intermediate) topics are consumed by downstream applications, it is your responsibility to adjust those downstream applications as appropriate when you reset the upstream application.
- Reset the local environment of your application instances. It is your responsibility to delete the local state on any machine on which an application instance was run.

See [Confluent Application Reset Tool](#) for additional reference information.

## Running the Application Reset Tool

Invoke the application reset tool from the command line:

```
/opt/mapr/bin/kafka-streams-application-reset.sh
```

The tool accepts the following parameters:

**NOTE:** Parameters can be combined as needed. For example, if you want to restart an application from an empty internal state, but not reprocess previous data, simply omit the `--input-topics` and `--intermediate-topics` parameters.

Option	Description
<code>--application-id &lt;String: id&gt;</code>	(Required) The Kafka Streams application ID ( <code>application.id</code> ).
<code>--default-stream</code>	The default stream that is used when the topic name is specified but the stream name is not.
<code>--config-file &lt;String: file name&gt;</code>	Property file containing configs to be passed to admin clients and embedded consumer.
<code>--dry-run</code>	Display the actions that would be performed without executing the reset commands.
<code>--input-topics &lt;String: list&gt;</code>	Comma-separated list of user input topics. For these topics, the tool will reset the offset to the earliest available offset.
<code>--intermediate-topics &lt;String: list&gt;</code>	Comma-separated list of intermediate user topics (topics used in the <code>through()</code> method). For these topics, the tool will skip to the end.

## Resetting your Local Environments

To reset the local environments of your application instances, you must delete your application's local state directory on any machines where the application instance was run. You must do this before restarting an application instance on the same machine. You can use either of these methods:

**NOTE:** This is a complete application reset

The API method `KafkaStreams#cleanUp()` in your application code. Manually delete the corresponding local state directory (default location: `/tmp/kafka-streams/<application.id>`). For more information, see `state.dir` `StreamsConfig` class.

## Example

In this example you are developing and testing an application locally and you want to iteratively improve your application via run-reset-modify cycles.

```
package mapr.examples.streams;

import ...;

public class ResetDemo {

 public static void main(String[] args) throws Exception {
 // Kafka Streams configuration
 Properties streamsConfiguration = new Properties();
 streamsConfiguration.put(StreamsConfig.APPLICATION_ID_CONFIG,
 "my-streams-app");
 // ...and so on...

 // Define the processing topology
 StreamsBuilder builder = new StreamsBuilder();
 builder.stream("my-input-topic")
 .selectKey(...)
 .through("rekeyed-topic")
 .countByKey("global-count")
 .to("my-output-topic");

 KStreams app = new KafkaStreams(builder.build(), streamsConfiguration);

 // Delete the application's local state.
 // Note: In real application you'd call `cleanUp()` only under
 // certain conditions. See tip on `cleanUp()` below.
 app.cleanUp();

 app.start();

 // Note: In real applications you would register a shutdown hook
 // that would trigger the call to `app.close()` rather than
 // using the sleep-then-close example we show here.
 Thread.sleep(30 * 1000L);
 app.close();
 }
}
```

You can then perform run-reset-modify cycles as follows:

```
Run your application
$ bin/kafka-run-class mapr.examples.streams.ResetDemo

After stopping all application instances, reset the application
```

```
$ bin/kafka-streams-application-reset.sh --application-id my-streams-app \
 --input-topics my-input-topic \
 --intermediate-topics rekeyed-topic

Now you can modify/recompile as needed and then re-run the application
again.
You can also experiment, for example, with different input data without
modifying the application.
```
